angioedema, also called **ANGIONEUROTIC EDEMA**, or **GIANT URTICARIA**, allergic disorder in which large, localized, painless swellings similar to hives appear under the skin. The swelling is caused by massive accumulation of fluid (edema) following exposure to an allergen (a substance to which the person has been sensitized) or, in cases with a hereditary disposition, after infection or injury. The reaction appears suddenly and persists for a few hours or days, occurring most often on the face, hands, feet, genitals, and mucous membranes.

A number of foods and drugs can precipitate allergic angioedema. The condition can usually be controlled with antihistamines or epinephrine and seldom poses serious danger to the affected person. In hereditary angioedema, caused by a defect in the immune system, swellings in the intestinal tract may produce pain, vomiting, or diarrhea, and edema of the larynx may cause death by asphyxiation. Hereditary angioedema usually first appears in late adolescence or early adulthood. It cannot be controlled by the same methods as allergic angioedema; however, drugs to treat this form have also been developed.

angiography, also called **ARTERIOGRAPHY**, radiographic examination of arteries and veins, one of the procedures of diagnostic imaging.

These structures cannot be differentiated from the surrounding organs in conventional radiography. It is therefore necessary to inject into the lumen of the vessels a substance that will distinguish them from the surrounding tissues. The contrast medium used is a water-soluble substance containing iodine. On the radiograph, iodine-containing structures cast a denser shadow than do other body tissues. The technique now in use was perfected in 1953.

A needle is used to puncture the main artery in the groin, armpit, or crook of the arm and to place a coiled wire in the artery. The needle is withdrawn, and a small, flexible hollow tube (catheter) is passed over the wire and into the artery. The wire is removed, and contrast medium is injected through the catheter. Both the arteries and the structures they supply with blood can be visualized. All organs of the body can be examined in this way. Radiographic evaluations of diseased arteries supplying the legs, the brain, and the heart are necessary before corrective surgical procedures are undertaken. *See also* angiocardiology.

Angiolieri, Cecco (b. c. 1260, Siena [Italy]—d. c. 1312), poet who is considered by some the first master of Italian comic verse.

It is known that Angiolieri married, had children, did military service, was exiled for a time, sometimes had trouble with the law, and was a lover of women, drink, and gambling. Apparently an irascible man, Angiolieri pours contempt in various sonnets upon his parents, his wife, his former mistress, and such contemporary poets as Dante and Guido Cavalcanti. Some critics, however, attribute his subject matter and attitude to the medieval goliard tradition, whose followers were writers of ribald and disrespectful verse, rather than to his own meanness of temper. In any event, poetic skill, vivid language, and a keen sense of the incongruities of life enliven his poems.

Angiolieri's works have been collected in *Sonetti burleschi e realistici dei primi due secoli* (1920; "Comic and Realistic Sonnets of the First Two Centuries") and in *Il canzoniere* (1946; "The Collection of Sonnets"), the latter a gathering of 150 poems. *The Sonnets of a Handsome and Well-Mannered Rogue*, translated by Thomas Chubb, appeared in 1970.

Angiolini, Gasparo, Gasparo also spelled **GASPARE**, pseudonym **ANGELO GASPARINI** (b. Feb. 9, 1731, Florence [Italy]—d. Feb. 6, 1803, Milan), Italian choreographer and composer who was among the first to integrate dance, music, and plot in dramatic ballets.

In 1757 he became ballet master of the Vienna court opera house, where his first ballet dramas frequently relied upon gesture to convey plot. In 1761, however, Angiolini collaborated with the composer Christoph Gluck to produce *Don Juan, ou le festin de pierre*, based on Molière's play of the same name; in this ballet much of the action was expressed through dance itself. In 1765 he choreographed the ballet *Sémiramis* to music by Gluck and in 1762 staged the ballet sequences in the original production of Gluck's *Orfeo ed Euridice*, which is significant in the history of opera for its dramatic unity and its increased emphasis on dance. In 1765 Angiolini became ballet master at the Imperial Theatre in St. Petersburg, where he choreographed several ballets to music of his own composition.

Angiolini's reforms were similar in basic intent to those of Christoph Willibald Gluck and Franz Hilverding; they also paralleled those of his rival, the choreographer Jean-Georges Noverre. In spite of their differences, both Angiolini and Noverre were instrumen-

tal in transforming ballet from its customarily disjointed, unemotional plots and emphasis on displays of technique to more expressive themes in which all elements were integrated.

angioma, congenital mass of blood vessels that intrudes into bone or other tissues, causing loss of tissue and, in the case of bone, structural weakening. Angiomas may occur in any bone and are often associated with angiomas of the skin or muscles. Most angiomas remain symptomless throughout life, but they may cause collapse of the vertebrae if they occur in the spine, and hemorrhage is a danger in some positions that expose them to stress. Treatment is usually by irradiation, which is supposed to cause clot formation within the mass of vascular tissue; it is believed the clot will then gradually calcify. Surgery is also done but involves a risk of hemorrhage.

angioneurotic edema: see angioedema.

angiosperm, any member of the more than 250,000 species of flowering plants (division Magnoliophyta) having roots, stems, leaves, and well-developed conductive tissues (xylem and phloem). Angiosperms are often differentiated from gymnosperms by their production of seeds within a closed chamber (the ovary), but this distinction is not always clear-cut. *Compare* gymnosperm.

A brief treatment of angiosperms follows. For full treatment, see MACROPAEDIA: Angiosperms.

The Magnoliophyta division is composed of two classes, the Liliopsida, or monocotyledons, and the Magnoliopsida, or dicotyledons. The embryo of monocots possesses one seed leaf (cotyledon) and the dicot embryo develops two. Other developmental differences that are used to distinguish the monocots include flower parts in threes, scattered conducting strands in the stem, and the absence of a cambium (the cell layer responsible for secondary growth). Dicots have flower parts in fours or fives, conducting strands arranged in a cylinder, and a cambium. Less reliable traits include the prominent parallel veins in a monocot leaf and the net-veined pattern of the leaf.

Angiosperms reflect an immense diversity in habit, size, and form. Species of angiosperms have been assigned to more than 300 families growing on every continent, including Antarctica. Some survive up to 1,000 years, while others live only a few weeks. They range in size from the floating duckweed, about 0.02 inch (0.5 mm), to *Eucalyptus regnans*, which grows to 300 feet (90 m).

Angiosperms have also adapted to an almost infinite variety of habitats—from freshwater lakes to brackish coastal waters; from rich, well-drained soils to arid desert regions and rocky ledges; from below sea level to high mountains.

Some angiosperms propagate vegetatively; *i.e.*, roots or stems (or sometimes other parts, or buds) can be separated from the main body and be planted. The great majority of angiosperms, however, reproduce principally by means of cross-pollination, *i.e.*, sexually. This reproduction by seeds involves the specialized reproductive organs (stamens or carpels or both) that are present in all flowers. After pollination and fertilization take place, the seed-bearing ovary matures and becomes the fruit, which may be dry (as is the case in a grain of wheat) or fleshy (as in a watermelon, tomato, or grape).

Angkor, archaeological site in what is now northwestern Cambodia, just 4 miles (6 km) north of the modern town of Siêm Réab. It was the capital of the Khmer (Cambodian) empire from the 9th to the 15th century. Its most imposing monuments are Angkor Wat, a temple complex built in the 12th century by King Suryavarman II (reigned 1113–c. 1150), and Angkor Thom, a temple complex built

about 1200 by King Jayavarman VII. (See also Southeast Asian arts.)

The city of Angkor served as the royal centre from which a dynasty of Khmer kings ruled one of the largest, most prosperous, and most sophisticated kingdoms in the history of Southeast Asia. From the last decade of the 9th century AD, when King Yaśovarman I moved his capital to Angkor, until the early years of the 13th century, the kings of Angkor ruled over a territory that extended from the tip of the Indochinese peninsula northward to Yunnan and from Vietnam westward to the

Ruined temples at Angkor Thom, Angkor, Cambodia
Emil Muench/Photo Researchers

Bay of Bengal. During this entire period, these rulers utilized the vast resources of labour and wealth at their disposal to carry through a series of prodigious construction projects designed to glorify both themselves and their capital city. After the reign of King Jayavarman VII (1181–c. 1215), the power and vitality of the kingdom gradually waned until finally, after Thai armies captured and sacked Angkor in 1431, the city was abandoned.

During the period of great construction and building at Angkor, which lasted more than 300 years, many changes in architecture and artistic style can be discerned, and there was a religious movement from the Hindu cult of the god Śiva to that of Vishnu to a Mahāyāna Buddhist cult devoted to the bodhisattva Avalokiteśvara.

Angkor was a centre for administration and for the worship of a divine monarch. The city was planned and constructed on the basis of religious and political conceptions imported from India and adapted to local traditions. From the time of Yaśovarman I, who gave the city its original name of Yaśodharapura, Angkor was conceived as a symbolic universe structured according to the model provided by the traditional Indian cosmology. The city was oriented around a central mountain or pyramid temple that was an architectural adaptation and completion of the one natural hill in the area, the Phnom Bakheng. In the later history of the city, the central temples were completely architectural creations (*i.e.*, pyramid temples), such as the Phimeanakas of Jayavarman V (reigned 968–1001); the Baphuon of Udayadityavarman II (reigned 1050–66); and the Buddhist temple of Bayon, which was the central temple built by Jayavarman VII when he gave the city, which by then had

become known as Angkor Thom, its more or less final form. The vast system of reservoirs, canals, and moats that were one of the most notable features of Angkor served primarily as a means of water control and irrigation.

Many of the great temples at Angkor, all of which gave expression to Indian cosmological and mythic themes, were built in order to provide a locus for cults through which kings and other members of the royal family could be assured of immortality through becoming identified with Śiva or one of the other preeminent gods of the realm. For example, Angkor Wat, which is perhaps the greatest and certainly the most famous of all the temples in the Angkor complex, was built by King Suryavarman II in the 12th century as a vast funerary temple within which his remains were to be deposited and his permanent identity with Vishnu symbolically and culturally confirmed.

In the late 13th century, according to the vivid account of the Chinese commercial envoy Chou Ta-kuan, Angkor was still a large, thriving metropolis and one of the most magnificent capitals in all of Asia. Nevertheless, by this time the great building frenzy that had culminated during the reign of Jayavarman VII had clearly come to an end, the new and more restrained religious orientation represented by Theravāda Buddhism was on the rise, and the armies of the Thai kingdoms established in the western sections of the empire were beginning to encroach on the Khmer heartland. By the 16th century, when the next available firsthand description was written, these trends had long since led to abandonment of the city, and all that remained were the jungle-covered remnants of the ancient temples and the ruins of the once-magnificent system of reservoirs and waterways.

During the more than four centuries between the demise of the ancient city and the beginning of the modern period (*i.e.*, from the early 15th century to the late 19th century), interest in Angkor was largely focused on Angkor Wat, which, having been taken over and kept largely intact by Theravāda Buddhist monks, became one of the most important pilgrimage sites in Southeast Asia. Even during this period, however, a number of early European visitors to Cambodia showed a strong curiosity concerning the “lost city,” and when the French colonial regime was established (1863), the entire site became the focus of an intense scholarly interest and concern. Working at first independently and then under the aegis of the government-sponsored French School of the Far East, a talented and dedicated group of French archaeologists and philologists initiated a comprehensive program of research, which has gradually yielded the knowledge now possessed about the history of the city and the fascinating religious and political system that informed and guided its life. Archaeologists also carried through an arduous and painstaking program of reconstruction, through which the ancient complex of temples, reservoirs, and canals was restored to something of its original grandeur.

During the political and military upheavals of the second half of the 20th century in Cambodia, there was some war damage and thievery among the temples at Angkor, but the major problem was one of neglect. Without adequate caretaking, the buildings became the prey of engulfing vegetation and eroding water and elements.

(F.E.R./Ed.)

God-kings (1973); Madeleine Giteau, *The Civilization of Angkor* (1976); and Michael Freeman and Roger Warner, *Angkor: The Hidden Glories* (1990).

anglaise (in calligraphy): see copperplate script

Angle, member of a Germanic people, which, together with the Jutes and Saxons, invaded England in the 5th century AD. The Angles gave their name to England, as well as to the word English, used even by Saxon writers to denote their vernacular tongue. The Angles are first mentioned by Tacitus (1st century AD) as worshipers of the deity Nerthus. According to the Venerable Bede in the *Ecclesiastical History of the English People*, their continental homeland was centred in Angulus, traditionally identified as the Angeln district in Schleswig between the Schlei inlet and the Flensburger Förde, which they appear to have abandoned at the time of their invasion of Britain. They settled in large numbers during the 5th and 6th centuries in the kingdoms of Mercia, Northumbria, and East and Middle Anglia.

anglerfish, any of about 210 species of marine fishes of the order Lophiiformes. Anglers are named for their method of "fishing" for their prey. The foremost spine of the dorsal fin is located on the head and is modified into a "fishing rod" tipped with a fleshy "bait." Prey fishes who are attracted to this lure stray close enough for the anglerfish to swallow them. Often bizarre in form, anglerfishes are also characterized by small gill openings and by limblike pectoral and (in some species) pelvic fins. Most species of anglerfishes inhabit the sea bottom. They are divided into four groups: batfish, goosefish, frogfish (*qq.v.*), and deep-sea angler.

The deep-sea anglers comprise about 10 families of the suborder Ceratioidei. Unlike other anglers, they lack pelvic fins, and they swim about, though feebly, rather than live on the bottom. They may be up to 1.2 m (4 feet) long, but most are much smaller. Only the females have a "fishing rod." This ranges from short to long, and the "bait"—almost always luminous—from simple to ornate. In some species there are also other luminous organs.

Deep-sea anglers prey on various fishes and invertebrates. Some have been known to swallow prey larger than themselves. Four families are notable for the fact that the males are very small in comparison with the females and, further, live as permanent parasites on their mates. In these species, the male attaches himself, by biting, to the body of the female. His mouth fuses with her skin, and the bloodstreams of the two fishes become connected, the male thereafter remaining totally dependent on the female for nourishment.

Anglesey, Isle of, Welsh YNYS MÔN, Latin MONA, county, northwestern Wales, separated from the North Wales mainland by the Menai Strait. The county encompasses Anglesey island—the largest island in England and Wales, with an area of 261 square miles (676 square km)—and Holy Island, adjoining just west of Anglesey. Isle of Anglesey county is coterminous with the historic county of Anglesey (Sir Fon). The highest point in the county is Holyhead Mountain, with an elevation of 720 feet (219 m), on Holy Island. Anglesey island has low relief, with a series of low ridges and valleys running from northeast to southwest.

Anglesey island is known for its ancient history and its prehistoric and Celtic remains. It is low and fertile, in contrast to the mountainous North Wales mainland, and hence it was an early grain-growing and stock-raising centre. Seafaring and fishing were also significant; islanders established early trading contacts

with Ireland and Mediterranean countries. Megalithic burial chambers and standing stones indicate late Neolithic and early Bronze Age habitation. By 100 BC the islanders had adopted Celtic language and culture. Anglesey became a famous Druid centre and a stronghold of resistance to the Romans; Suetonius Paulinus invaded in AD 61, slaying Druid priests and destroying sacred groves, and Agricola completed the conquest in 78. Early Celtic Christian churches and monasteries on Anglesey include Penmon Priory. Aberffraw, on the southwest coast, was the capital of the Gwynedd princes from the 7th to the 13th century. Highly exposed to invasion from the sea, the island was attacked by Irish, Saxon, Viking, and Norman venturers. It was finally subdued by the English king Edward I, who built the castle at Beaumaris (begun 1295).

Isle of Anglesey county remains predominantly agricultural, but tourism has become important. The market town of Llangefni, on Anglesey island, is the county's administrative centre. The main town on Holy Island is Holyhead. Area county, 276 square miles (715 square km). Pop. (1998 est.) county, 65,400.

Where the same name may denote a person, place, or thing, the articles will be found in that order

anglesite, naturally occurring lead sulfate ($PbSO_4$). A common secondary mineral that is a minor ore of lead, it is usually formed by the oxidation of galena and often forms a concentrically banded mass surrounding a core of unaltered galena. The formation of cerussite (lead carbonate) often accompanies or follows the formation of anglesite. For detailed physical properties, see sulfate mineral (table).

Angleterre, in full POINT D'ANGLETERRE (French: "English lace"), bobbin lace comparable to fine Brussels lace in thread, technique, and design; but whether it was made in England or Brussels or both is debatable.

Angleterre lace from Belgium, late 19th century; in the Institut Royal du Patrimoine Artistique, Brussels

By courtesy of the Institut Royal du Patrimoine Artistique, Brussels, photograph, © A.C.L., Brussels

To encourage home industries, both England and France had laws in the 1660s prohibiting the importation of Brussels lace, which was much in demand. To circumvent these laws, merchants bought Brussels lace and took it, often by smuggling, to England and to France (which had no restrictions against English lace) for sale as point d'Angleterre.

angleworm: see earthworm.

Anglia, Middle: see Middle Anglia.

Anglican chant, simple harmonized setting of a melodic formula devised for singing prose versions of the psalms and canticles in the Anglican Church. The formula is made up of a reciting tone with middle and final cadences (mediation and termination), much like the Gregorian-chant psalm tones from which Anglican chant derives. When John Marbeck published *The Booke of Common Praier Noted* (1550), he used the first seven psalm tones for the canticles and tone eight for the psalms. Like Marbeck, various English composers used the psalm tones in their polyphonic (multipart) psalm settings, placing them in the tenor part "measured," i.e., with a regular metrical pattern. The harmonic style of these polyphonic settings was probably derived from the continental *falsobordone* style, which also employed the plainsong psalm tones but in the topmost voice. The double chant (two successive verses set to different melodic formulas) traditionally dates from about 1700, but Robert Crowley's psalter (1549) contains what is virtually the same thing. Triple and even quadruple forms also exist.

When the Restoration of the English monarchy was effected in 1660 and choirs and organists returned to their posts, a great need was felt for cathedral choral service settings. Thus, plainsong harmonizations again appeared, as in James Clifford's *Divine Services and Anthems Usually Sung in Cathedral and Collegiate Choirs in the Church of England* (1663). By the end of the 17th century English composers began to write their own melodies, using the recitation note and the cadences of the psalm tone as a framework but omitting intonation. In the 18th century the psalm tone melody was placed in the upper part if it was used at all.

After the Oxford Movement (promoting a re-orientation toward Roman Catholic liturgy) began in 1833, parish churches turned to choral services, formerly confined to cathedrals. To facilitate better singing by lesser trained choirs, a method of pointing the psalms first appeared in printed form in 1837—a system of signs that pointed out how a text was to be fitted to a given chant.

A renewed interest in Gregorian chant sung in the vernacular was promoted by the Plainsong and Mediaeval Music Society (founded 1888). Francis Burgess in England and C. Winfred Douglas in the United States had great influence in the movement. In 1912 the English poet Robert Bridges pointed out that the chant must be fitted to the words and not the other way around. He gained the support of Dr. Hugh Allen at Oxford, and in 1925 the *Psalter Newly Printed* was published.

Anglican Church of Australia, formerly (until 1981) CHURCH OF ENGLAND IN AUSTRALIA, independent Australian church within the Anglican Communion. It developed from the churches established by the English settlers in Australia in the 18th century. The first settlers, convicts sent from England to settle the country in 1788, were accompanied by one chaplain. Subsequently, more settlers and priests went to Australia. For many years the bishop of London was officially responsible for all British subjects outside Britain, but in 1814 Australia was included in the area of the new bishop of Calcutta. In 1836 the diocese of Australia was founded, and William Grant Broughton, who went to Australia in 1829, was consecrated as the first bishop. A period of expansion and church building then occurred, and in 1847 Broughton became bishop of Sydney when the dioceses of Melbourne, Adelaide, and Newcastle were established with their own bishops.

Over the years the church continued to grow as the population of Australia increased and

expanded into new territories. Additional dioceses were established, and eventually five provinces of the church were organized, each composed of several dioceses. General Synods of the entire church were held every five years, with the primate of Australia, elected from the diocesan bishops, as president. For many years, however, the Australian church did not attain complete independence from the Church of England, because it lacked a constitution that clearly defined the legislative powers of the General Assembly. Dioceses and provinces experienced independence. After years of discussion and several unsuccessful attempts, a constitution was accepted in 1959, and the Church of England in Australia became autonomous in 1962.

Anglican Communion, religious body of national, independent, and autonomous churches throughout the world that evolved from the Church of England. The Anglican Communion is united by a common loyalty to the archbishop of Canterbury in England as its senior bishop and titular leader and by a general agreement with the doctrines and practices defined in the 16th-century *Book of Common Prayer*.

A brief treatment of the Anglican Communion follows. For full treatment, see MACROPAEDIA: Protestantism: *Anglican Communion*. For further information on the history of Anglicanism, see MICROPAEDIA articles on individual Anglican churches (e.g., England, Church of; Protestant Episcopal Church).

From the time of the Reformation, the Church of England followed explorers, traders, colonists, and missionaries into the far reaches of the known world. The colonial churches generally exercised administrative autonomy within the historical and creedal context of the mother church. It was probably not until the first meeting of the Lambeth Conference (q.v.) in 1867 that there emerged among the various churches and councils a mutual consciousness of an Anglican Communion. Since its inception, the Lambeth Conference has constituted the principal cohesive factor in Anglicanism.

While population differences and other factors account for some variation in the basic structure among the churches, several elements do predominate. The diocese, under the administration of a bishop, is the basic administrative unit throughout the Communion. The diocese is made up of parishes, or local church communities, each under the care of a pastor. In many of the national churches, dioceses are grouped into provinces. In some, parishes may be grouped also below the diocesan level into rural deaneries and archdeaconries.

In the 20th century the Anglican Communion played a prominent role in the ecumenical movement. A milestone in Anglican-Roman Catholic relations was reached in 1982 when Pope John Paul II met with Robert Runcie, the archbishop of Canterbury, at Canterbury to discuss prospects for reconciliation between the two churches. Obstacles emerged, however, in 1989 when the Anglican Communion began to ordain women as priests and bishops and in 2003 when V. Gene Robinson, an openly gay man, was consecrated in the United States as the Anglican bishop of New Hampshire. Robinson's consecration provoked controversy within the Anglican Communion, and several Anglican churches broke off relations with the church in the United States. The Communion's approval of blessing same-sex unions also met with opposition from Anglican and non-Anglican churches.

Anglican Evangelical, one who emphasizes biblical faith, personal conversion, piety, and, in general, the Protestant rather than the Catholic heritage of the Anglican Communion. Such persons have also been referred to as low churchmen because they give a "low" place to the importance of the episcopal form

of church government, the sacraments, and liturgical worship. The term Low Church was used by the end of the 17th century, although this emphasis within Anglicanism was evident since the time of King Edward VI (1547-53).

The movement that became known as the Evangelical movement began within the Church of England in the 18th century, although it had many points in common with earlier Low Church attitudes and with 16th- and 17th-century Puritanism. The followers of John Wesley, the founder of Methodism, eventually left the Church of England, but many with very similar beliefs remained within the established church. They emphasized evangelism, social welfare, and missions, and they established the Church Missionary Society (1799) and the Colonial and Continental Church Society (1838). Included among the Evangelicals' many leaders were the influential Clapham Sect, a group of wealthy lay persons prominent in England from about 1790 to 1830. Many of them were members of Parliament, and they were responsible for ending the slave trade.

In the 19th century the Evangelicals opposed the Oxford Movement, which emphasized the Catholic heritage of Anglicanism. In the 20th century they were influenced by liberalism and the new, scientific methods of studying the Bible. (See Broad Church.) Some continued to stress the verbal inspiration and accuracy of the Bible and became known as conservative Evangelicals. Others, a much larger group, accepted the new learning and became known as liberal Evangelicals. In general, they continued as the Low Church party within the Anglican Communion.

Anglican religious community, any of various religious communities for men and for women that first began developing within the Anglican Communion in the 19th century. Although monastic communities were numerous in the pre-Reformation English Church, they were suppressed in the 16th century by Henry VIII when he broke with the Roman Catholic church. Their revival was due primarily to the interest and encouragement of some of the leaders of the Oxford Movement, who emphasized the Catholic rather than the Protestant heritage of Anglicanism.

The first community, the Sisterhood of the Holy Cross, was founded in London in 1845. In the following 10 years the Society of the Holy Trinity at Devonport (1845); the Community of St. John the Baptist at Clewer, near Windsor (1851); the Community of All Saints, London Colney, Hertfordshire (1851); and the Society of St. Margaret at East Grinstead, Sussex (1855) were founded. Notable among later 19th-century foundations were the Community of the Holy Name, Malvern Link, Worcestershire (1865); the Sisters of Bethany, London (1866); and the Community of the Epiphany, Truro (1883).

Almost all the sisterhoods combined an active life (teaching, nursing, helping in parishes, etc.) with a life of prayer and worship. Anglican sisters were among those who accompanied Florence Nightingale to the Crimea and took part in the work of raising the standards and status of the nursing profession. In various forms of social and educational work the Anglican sisterhoods offered opportunities of service not readily available to women in mid-19th-century England, but the religious motive predominated in the revival.

Many English sisterhoods opened branch houses abroad, and independent communities were founded in other provinces of the Anglican Communion. In the United States the oldest surviving sisterhood is the Community of St. Mary at Peekskill, N.Y. (1865); in Canada there is the Sisterhood of St. John the Divine (1884), at Willowdale, Ontario, and in Australia the Community of the Holy Name (1886), at Melbourne.

During the 20th century the foundation of new communities continued, though at a slower rate. A number of enclosed communities of contemplative nuns were established both in England and in the United States.

The first Anglican religious community for men was the Society of St. John the Evangelist (the Cowley Fathers), founded in 1866 at Oxford. Since then numerous other communities or brotherhoods have been founded in England. The largest men's communities are the Community of the Resurrection (Mirfield Fathers), founded in 1892 at Mirfield, Yorkshire, and the Society of St. Francis, Cerne Abbas, Dorset, founded in 1921. An Anglican Benedictine community was established at Pershore in 1914 and moved to Nashdom Abbey, Burnham, Buckinghamshire, in 1926. It has a branch house in the United States. The only indigenous men's community of any size in the Protestant Episcopal Church in the United States is the Community of the Holy Cross, West Park, N.Y. (1881).

In the late 20th century more than 50 Anglican religious communities for men and for women, many with several houses or branches, were in existence. Several English communities have branch houses overseas. In general the communities are not large.

The Anglican Communion has never made provision for religious communities in canonical legislation, and the relations of the communities with the ecclesiastical authorities were at first vague and undefined. Since 1935 it has been possible for those in England to obtain formal recognition from the advisory council on religious communities established for the provinces of Canterbury and York.

Anglin, Margaret (Mary) (b. April 3, 1876, Ottawa—d. Jan. 7, 1958, Toronto), one of the most brilliant actresses of her day, equally effective in Greek tragedies, Shakespearean plays, and contemporary dramas.

After a brief study of acting in New York City, she made her debut (1894) in Bronson C. Howard's *Shenandoah*. She achieved stardom in 1898 as Roxane in Edmond Rostand's *Cyrano de Bergerac*. She was a great success in William Vaughn Moody's *Great Divide*, which ran for almost three years (1906-08) in New York City. By her own estimate, she appeared in more than 80 plays. Her last appearance was in 1943 with a touring company of Lillian Hellman's *Watch on the Rhine*.

angling: see fishing.

Anglo-Afghan Wars, also called AFGHAN WARS (1839-42; 1878-80; 1919), three conflicts in which Great Britain, from its base in India, sought to extend its control over neighbouring Afghanistan and to oppose Russian influence there. The first war demonstrated the ease of overrunning Afghanistan and the difficulty of holding it. The second war proved to be a Pyrrhic victory for the British.

Though unable to occupy Afghanistan permanently, the British controlled its foreign affairs until the last war established full Afghan independence.

Anglo-America, cultural entity of North America whose common spoken language is English and whose folkways and customs historically have been those of northern Europe. It comprises most of the United States and Canada, with French-speaking Canada a notable exception. The term also designates a geographical area on the North American continent as apart from Latin, Spanish, or Ibero-America (comprising Middle and South America) with strong Hispanic traditions and heritage. The expression Anglo has come to signify a white, English-speaking North American as distinct from one of Latin-American descent.

Anglo-American law: *see* common law.

Anglo-Boer War: *see* South African War.

Anglo-Burmese Wars (1824–26, 1852, 1885), three conflicts that collectively forced the Burmese into a vulnerable position from which they had to concede British hegemony in the region of the Bay of Bengal. The First Anglo-Burmese War arose from friction between Arakan in western Burma and British-held Chittagong to the north. After Burma's defeat of the kingdom of Arakan in 1784–85, Arakanese refugees went north into British territory and from their sanctuaries in Bengal formed armed contingents and recrossed the border, attacking Burmese garrisons in Arakan. At one point, Arakanese patriots recaptured the provincial capital of Mrohaung. In retaliation, Burmese forces crossed into Bengal, withdrawing only when challenged by Bengal authorities.

In 1823 Burmese forces again crossed the frontier; and the British responded in force, with a large seaborne expedition that took Rangoon (1824) without a fight. The British hope of making the Burmese submit by holding the delta region and threatening the capital failed as Burmese resistance stiffened. In 1825 the British Indian forces advanced northward. In a skirmish south of Ava, the Burmese general Bandula was killed and his armies routed. The Treaty of Yandabo (*see* Yandabo, Treaty of; February 1826) formally ended the First Anglo-Burmese War. The British victory had been achieved mainly because India's superior resources had made possible a sustained campaign running through two rainy seasons. But in the fighting the British-led Indian troops had suffered more than 15,000 fatalities.

After 25 years of peace, the British Indian government sent a naval officer, Commodore Lambert, to Rangoon to investigate British merchants' complaints of extortion. When Lambert seized a ship that belonged to the Burmese king, another war began.

By July 1852 the British had captured the ports of Lower Burma and had begun a march on the capital. Slowly but steadily the British-Indian forces occupied the central teak forests of Burma. The new king Mindon Min (ruled 1853–78) requested the dispersal of British forces. The British were unreceptive but were hesitant to advance farther northward; with both sides at an impasse, the fighting simply ceased. The British now occupied all Lower Burma but without formal recognition of the Burmese court.

Mindon tried to readjust to the thrust of imperialism. He enacted administrative reforms and made Burma more receptive to foreign interests. To offset the British, he entertained envoys from France and sent his own emissaries there. Those moves aroused British suspicions, and Anglo-Burmese relations once again worsened. During the reign of Thibaw (1878–85), the British were willing to ignore Upper Burma and to concentrate on French moves in Laos, Vietnam, and Yunnan.

The ensuing Anglo-French tension was the result not so much of French design as of Burmese initiative. A letter to the French premier from the Hlutdaw (ministerial council) suggesting a bilateral treaty posed a direct threat to British teak monopolies in Lower Burma. Meanwhile, the Hlutdaw fined the Bombay Burmah Trading Corporation for underreporting its extractions of teak from Toungoo. That action provoked British forces to strike. The annexation of Upper Burma was announced on Jan. 1, 1886, ending the Konbaung dynasty and Burmese independence. The Third Anglo-Burmese War formally ended before it had even developed, but resistance to British rule continued for another four years.

Anglo-Catholicism, movement that emphasizes the Catholic rather than the Protestant heritage of the Anglican Communion. It was an outgrowth of the 19th-century Oxford Movement (*q.v.*), which sought to renew Catholic thought and practice in the Church of England. The term Anglo-Catholic was first used in some of the writings of leaders of the Oxford Movement who wished to demonstrate the historical continuity of the English (Anglican) Church with Catholic Christianity.

In addition to stressing Catholic elements in worship and theology, Anglo-Catholics have worked among the poor and unchurched and have attempted to renew the church. Although their beliefs and activities have often been opposed by Anglican Evangelicals, who stress the Protestant heritage of Anglicanism, Anglo-Catholics have continued to be an important force within the Anglican Communion.

Anglo-Catholics are sometimes called high churchmen, in that they give a "high" place to the importance of the episcopal form of church government, the sacraments, and liturgical worship. The term High Church was first used about the end of the 17th century to express this particular emphasis within the Church of England. Historically, however, High Church attitudes, like Low Church (Evangelical) attitudes, were evident within the Church of England from the time of Elizabeth I (1533–1603). The Oxford Movement and Anglo-Catholicism renewed this emphasis within Anglicanism. *See also* Broad Church.

Anglo-Dutch Wars, also called **DUTCH WARS**, **Dutch ENGELSE OORLOGEN** (English Wars), the four 17th- and 18th-century naval conflicts between England and the Dutch Republic. The first three wars, stemming from commercial rivalry, established England's naval might, and the last, arising from Dutch interference in the American Revolution, spelled the end of the republic's position as a world power.

The First Anglo-Dutch War (1652–54) began during a tense period following England's institution of the 1651 Navigation Act, which was aimed at barring the Dutch from involvement in English sea trade. An incident in May 1652 resulting in the defeat of a Dutch force under Adm. Maarten Tromp led England to declare war on July 8 (June 28, old style). The Dutch under Tromp won a clear victory off Dungeness in December, but most of the major engagements of the following year were won by the larger and better armed men-of-war of England. In the summer of 1653 off Texel (Terheide), in the last battle of the war, the Dutch were defeated and Tromp killed, with both sides suffering heavy losses. The war was ended by the Treaty of Westminster (April 1654).

The commercial rivalry of the two nations again led to war in 1665 (the Second Anglo-Dutch War of 1665–67), after hostilities had begun the previous year and the English had already captured New Amsterdam (New York). England declared war in March 1665 and won a victory over the Dutch off Lowestoft in June. Most subsequent battles (which occurred in the following year), however, were won by the Dutch. England's ally, the principality of Münster, sent troops into Dutch territory in 1665 but was forced out of the war in the following year by France, which took the Dutch side in January 1666. A plague epidemic in 1665 and the Great Fire of London in 1666 contributed to England's difficulties, which culminated in the destruction of its docked fleet by the Dutch at Chatham in June 1667. The war was ended the following month by the Treaty of Breda.

The Third Anglo-Dutch War (1672–74) formed a part of the general European war of 1672–78 (*see* Dutch War).

England and the Dutch Republic had been allied for a century when they again went to

war (the Fourth Anglo-Dutch War of 1780–84) over secret Dutch trade and negotiations with the American colonies, then in revolt against England. The English declared war on Dec. 20, 1780, and, in the following year, quickly took key Dutch possessions in the West and East Indies while imposing a powerful blockade of the Dutch coast. In the only significant engagement of the war, a small Dutch force won a victory off Dogger Bank in August 1781. The republic was never able to assemble a proper fleet for combat, however, and when the war ended in May 1784, the Dutch were at the nadir of their power and prestige.

Anglo-Egyptian Condominium, the joint British and Egyptian government that ruled the eastern Sudan from 1899 to 1955. It was established by the Anglo-Egyptian Condominium Agreements of Jan. 19 and July 10, 1899, and, with some later modifications, lasted until the formation of the sovereign, independent Republic of The Sudan on Jan. 1, 1956. (The Anglo-Egyptian Agreement of 1953 had outlined the steps to be taken for Sudanese self-rule and self-determination.)

The Condominium agreements established an office of governor-general, to be appointed, on British recommendation, by the khedive of Egypt and vested with supreme civil and military command. In theory, Egypt shared a governing role; but in practice the structure of the Condominium ensured full British control over the Sudan. The governors and inspectors were customarily British officers, though technically serving in the Egyptian Army; and key figures in the government and civil service always remained graduates of British universities and military schools.

Anglo-Egyptian Treaty (Aug. 26, 1936), treaty, signed at Montreux, Switz., in May 1937, establishing Egypt as a sovereign state after 50 years of British occupation. The 20-year military alliance allowed Great Britain to impose martial law and censorship in Egypt in the event of international emergency; provided for the stationing of up to 10,000 British troops and 400 Royal Air Force pilots in the Suez Canal Zone until the Egyptians should be capable of protecting the area; and permitted Great Britain to retain its naval base at Alexandria for a maximum of eight years. Further, a British ambassador to Egypt replaced the former high commissioner. After a transitional period, the Capitulations (*q.v.*) were to be abolished, and, with the additional extinction of the Mixed Courts, foreigners would be subject to Egyptian law.

Anglo-Japanese Alliance (1902–23), alliance that bound Britain and Japan to assist one another in safeguarding their respective interests in China and Korea. Directed against Russian expansionism in the Far East, it was a cornerstone of British and Japanese policy in Asia until after World War I.

The alliance served Japan in the Russo-Japanese War (1904–05) by discouraging France, Russia's European ally, from entering the war on the Russian side. It was renewed in 1905 and again in 1911 after Japan's annexation of Korea. On the basis of its tie with Britain, Japan participated in World War I on the side of the Allies.

After the war the British no longer feared Russian encroachment in China and wished to maintain close ties with the United States, which tended to view Japan as its rival in the Pacific. Following an unsuccessful attempt to bring the U.S. into the alliance at the Washington Conference of 1921–22, Britain allowed it to lapse. It was specifically terminated by the Four-Power Pacific Treaty (1921), a vaguely worded agreement that left the Japanese without allies until the conclusion of their Tripartite Pact with Germany and Italy in September 1940.

Anglo-Norman literature, also called NORMAN-FRENCH LITERATURE, or ANGLO-FRENCH LITERATURE, body of writings in the Old French language as used in medieval England. Though this dialect had been introduced to English court circles in Edward the Confessor's time, its history really began with the Norman Conquest in 1066, when it became the vernacular of the court, the law, the church, schools, universities, parliament, and later of municipalities and of trade. For the English aristocracy, Anglo-Norman became an acquired tongue and its use a test of gentility. It was introduced into Wales and Ireland and used to a limited extent in Scotland. The earliest extant literary texts in the Anglo-Norman dialect belonged to the reign of Henry I in the early 12th century, the latest to that of Henry IV in the early 15th century. The alienation toward France during the Hundred Years' War started an increasing use of English, the last strongholds of a French dialect being Parliament and the law, in both of which it still survives in a few formulas.

From the 12th through the 14th century, Anglo-Norman was second only to Latin in its use as a literary language in England. Most types of literary works were represented in Anglo-Norman as in French, with a slight difference of emphasis. The *chanson de geste* was an exception; this type of French epic poem was not unknown in England, but there seem to have been no original works of the kind written there. Conversely, Anglo-Norman works were known, copied, or imitated on the Continent. One important difference between continental and Anglo-Norman literature is that the Fourth Lateran Council of 1215 led to an outpouring of doctrinal and devotional works for the laity in England not paralleled in France, which perhaps explains the fact that in the early periods England was often in advance of the Continent in the development of new literary forms. Historical writing was popular both in Normandy and in the rest of the Continent; and although, after the Norman Conquest, Latin replaced English for use in documents and chronicles, examples of both are found in Anglo-Norman. Religious houses caused lives of native saints to be written, and the nobility had a taste for romances about imaginary English ancestors. Thus social and political differences between the two countries prevented Anglo-Norman literature from being a mere provincial imitation of French.

Religious and didactic writings. In the 12th century the oldest substantial Anglo-Norman prose work, "The Book of Kings," was written in England, as were many versions of the Psalter. Sanson de Nanteuil translated into verse the proverbs of Solomon, with commentary; and in the 13th century Robert of Greatham wrote the "Sunday Gospels" for a noble lady. The same century saw the beginning of the magnificent series of Anglo-Norman apocalypses, best known for their superb illustrations, which served as a model for a series of tapestries at Angers, France. Anglo-Norman was rich in literature of legends of saints, of which Benedeit's "Voyage of St. Brendan" was perhaps the oldest purely narrative French poem in the octosyllabic couplet. Wace led the way in writing a saint's life in standard form but was followed by Anglo-Norman writers in the 12th century who wrote numerous biographies, many connecting religious houses with their patron saints.

The earliest play entirely in French, the *Mystère d'Adam*, is Anglo-Norman. The resurrection play *La Sainte Resurreccion* was probably 12th century but was rewritten more than once in the 13th century. There were a few religious allegories, the most important, the "Castle of Love," being the oldest in French.

The Fourth Lateran Council of 1215 led to the compilation of instructive works, the oldest and most attractive being the *Merure de*

seinte église ("Mirror of Holy Church") by St. Edmund of Abingdon. In the 13th–14th century countless treatises appeared on technical subjects—manuals for confession, agriculture, law, medicine, grammar, and science, together with works dealing with manners, hunting, hawking, and chess. Spelling treatises produced in the late 13th, 14th, and 15th centuries are valuable for the light they shed on continental French as well as Anglo-Norman.

Romances. Anglo-Norman literature was well provided with romances. In the 12th century one Thomas wrote a courtly version of the Tristan story, which survived in scattered fragments and was used by Gottfried von Strassburg in *Tristan und Isolde* as well as being the source of the Old Norse, Italian, and Middle English versions of the story. Béroul's *Tristan*, also 12th century, was probably written in England, but by a Norman; *Waldef*, a long, confused story of an imaginary king of East Anglia and his sons, has passages of remarkable originality. In the 12th century some romances were composed in the form of the *chanson de geste*; for example, *Horn*, by Master Thomas, which is connected with the Middle English *Horn Childe and Maiden Rinnild*. Yet another Thomas wrote the *Roman de toute chevalerie* ("Romance of All Chivalry"), an independent version of the Alexander romance and the source of the Middle English romance *King Alisaunder*. In the 13th century the more courtly type of romance reappeared in *Amadas et Idoine* and in *Amis et Amiloun*.

Lais and fabliaux. Marie de France, the earliest named French woman poet, wrote fables based on an English source and 12 narrative lays (dedicated, probably, to Henry II of England) in octosyllabic rhymed couplets. A few other fabliaux have been found copied in manuscripts from religious houses, probably for exemplary purposes.

Political and historical writings. Fragments of political songs are found in Peter Langtoft's *Chronicle*, which begins as a *Brut*—a complete chronicle of British history—but became a source for the times of Edward I. The Dominican Nicholas Trevet wrote a prose chronicle of European history from which Chaucer derived his "Man of Law's Tale." Earlier than these was an Anglo-Norman verse, *Estoire des Engleis*, by Geffrei Gaimar (c. 1140), which is the earliest chronicle in French. Two magnificent biographies of the 1st Earl of Pembroke (William Marshal) and of Edward, the Black Prince, were written for English patrons by foreigners. Official documents were often in Anglo-Norman, and the *Yearbooks*, unofficial reports of cases in the common pleas, ran from the reign of Edward I to that of Henry VIII. English began to be used in Parliament alongside French in the late 14th century.

(D.Lc.)

Anglo-Saxon, any member of the Germanic peoples that inhabited and ruled England from the 5th century AD to the time of the Norman Conquest (1066). According to the Venerable Bede, the Anglo-Saxons were the descendants of three different Germanic peoples—the Angles, Saxons, and Jutes—who originally migrated from northern Germany to England in the 5th century at the invitation of the British chieftain Vortigern to defend his country against Pictish and Irish invaders. Their subsequent settlements in what is now England laid the foundation for the later kingdoms of Essex, Sussex, and Wessex (Saxons), East Anglia, Middle Anglia, Mercia, and Northumbria (Angles), and Kent (Jutes). The various Anglo-Saxon kingdoms spoke dialects of what is now known as Old English. Ethnically, the "Anglo-Saxons" actually represented an admixture of Germanic peoples with England's preexisting

Celtic inhabitants and subsequent Viking and Danish invaders.

The term "Anglo-Saxon" seems to have been first used by continental writers in the late 8th century to distinguish the Saxons of Britain from those of the European continent, whom the Venerable Bede had called *Antiqui Saxones* ("Old Saxons"). After the Norman Conquest, the term simply came to mean "the English." The name formed part of a title, *rex Angul-Saxorum* ("king of the Anglo-Saxons"), which was sometimes used by King Alfred (d. 899) and was revived by 11th-century kings.

Anglo-Saxon art, manuscript illumination and architecture produced in Britain from about the 7th century to the Norman Conquest of 1066. Anglo-Saxon art may be divided into two distinct periods, one before and one after the Danish invasions of England in the 9th century.

Before the 9th century, manuscript illumination was the major art in Britain. There were two schools of illumination: a somewhat limited one at Canterbury, which produced works

Page of interlaced designs from the Book of Durrow, Hiberno-Saxon, 7th century; in Trinity College Library, Dublin

influenced by the Roman missionaries who began the Christian conversion of southern England and ensured that models within the classical tradition were used through the 8th century; and a more widely influential school that flourished in Northumbria. Manuscript illumination in northern England received its impetus from a revival of learning initiated in the 7th century by the establishment of monasteries on the island of Lindisfarne and at Wearmouth and Jarrow in Northumbria, institutions that were largely an extension of the Irish monastic system. The Irish monks carried with them an ancient Celtic decorative tradition of curvilinear forms—scrolls, spirals, and a double curve, or shield, motif known as a pelta—that were integrated with the abstract ornamentation of the native pagan Anglo-Saxon metalwork tradition, characterized particularly by bright coloring and zoomorphic interlace patterns. The additional influence, from southern England, of Mediterranean art introduced the representation of the human figure. The characteristics of Hiberno-Saxon art, however, remained basically those of pagan art: concern for geometric design rather than naturalistic repre-

sentation, love of flat areas of colour, and the use of complicated interlace patterns. All of these elements appear in the great manuscripts produced by the Hiberno-Saxon school: the Lindisfarne Gospels (early 8th century), the Book of Durrow (7th century), and the Book of Kells (c. 800). The Hiberno-Saxon style (*qv.*), eventually imported to the European continent, exercised great influence on the art of the Carolingian empire.

The Danish invasions had a disastrous effect on Anglo-Saxon art that was felt until mid-10th century, when the monasteries were revived and interest in architecture grew strong. Some idea of the architecture of the period can be deduced from contemporary descriptions and the excavation of remains. Many of the early stone churches seem to have depended upon the contribution of foreign masons, and Anglo-Saxon building, which consisted mainly of extremely small churches attached to monasteries, continued to be heavily influenced by continental types. By the 11th century, ties with continental architecture, especially that of Norman France, were strong; King Edward the Confessor's Romanesque Westminster Abbey (begun c. 1045–50, replaced in 1245 by the present Gothic church), for example, was similar in plan to French models, being cruciform with one central and two western towers. Certain features, however, distinguish Anglo-Saxon architecture: the frequent use of timber for construction; a square, eastern termination (a feature revived in English Gothic churches) instead of the almost universal apse, or semicircular projection, behind the altar; and certain distinctive masonry techniques.

The monastic revival resulted in a vast production of books and the flowering, by the second half of the 10th century, of the so-called Winchester school of illumination. The new style was based on the classical naturalism of Carolingian art, but it was highly individual and unusually vivacious, characterized especially by a nervous, highly expressive line. Masterpieces in both painting and drawing have survived; for example, the Benedictional of St. Aethelwold, produced at Winchester in the 10th century, and a copy of the Utrecht Psalter begun at Canterbury in about 1000. The Winchester style influenced French illumination to the extent that Norman art was reasonably acceptable to English illuminators after the conquest of 1066. *See also* Winchester school.

Anglo-Saxon Chronicle, chronological account of events in Anglo-Saxon and Norman England, a compilation of seven surviving interrelated manuscript records that is the primary source for the early history of England. The narrative was first assembled in the reign of King Alfred (871–899) from materials that included some epitome of universal history: the Venerable Bede's *Historia ecclesiastica gentis Anglorum*, genealogies, regnal and episcopal lists, a few northern annals, and probably some sets of earlier West Saxon annals. The compiler also had access to a set of Frankish annals for the late 9th century. Soon after the year 890 several manuscripts were being circulated; one was available to Asser in 893, another, which appears to have gone no further than that year, to the late 10th-century chronicler Aethelweard, while one version, which eventually reached the north and which is best represented by the surviving E version, stopped in 892. Some of the manuscripts circulated at this time were continued in various religious houses, sometimes with annals that occur in more than one manuscript, sometimes with local material, confined to one version. The fullness and quality of the entries vary at different periods; the Chronicle is a

rather barren document for the mid-10th century and for the reign of Canute, for example, but it is an excellent authority for the reign of Aethelred the Unready and from the reign of Edward the Confessor until the version that was kept up longest ends with annal 1154.

The Chronicle survived to the modern period in seven manuscripts (one of these being destroyed in the 18th century) and a fragment, which are generally known by letters of the alphabet. The oldest, the A version, formally known as C.C.C. Cant. 173 from the fact that it is at Corpus Christi College, Cambridge, is written in one hand up to 891 and then continued in various hands, approximately contemporary with the entries. It was at Winchester in the mid-10th century and may have been written there. It is the only source for the account of the later campaigns of King Edward the Elder. Little was added to this manuscript after 975, and in the 11th century it was removed to Christ Church, Canterbury, where various interpolations and alterations were made, some by the scribe of the F version. The manuscript G, formally known as Cotton Otho B xi (from the fact that it forms part of the Cotton collection of manuscripts at the British Museum), which was almost completely destroyed by fire in 1731, contained an 11th-century copy of A, before this was tampered with at Canterbury. Its text is known from a 16th-century transcript by L. Nowell and from Abraham Wheloc's edition (1644).

The B version (Cott. Tib. A vi) and the C version (Cott. Tib. B i) are copies made at Abingdon from a lost archetype. B ends at 977, whereas C, which is an 11th-century copy, ends, mutilated, in 1066. Their lost original incorporated into the text in a block after annal 915 a set of annals (902–924) known as the Mercian Register.

The D version (Cott. Tib. B iv) and the E version (kept at the Bodleian Library, Oxford, Laud Misc. 636) share many features, including the interpolation of much material of northern interest taken from Bede and from annals also used by Simeon of Durham; hence they are known as the "northern recension." D has also dovetailed into its text the Mercian Register and contains a fair amount of northern material found in no other version. It is quite detailed in the English descent of Queen Margaret of Scotland. D, which is kept up until 1079, probably remained in the north, whereas the archetype of E was taken south and continued at St. Augustine's, Canterbury, and was used by the scribe of manuscript F.

The extant manuscript E is a copy made at Peterborough, written in one stretch until 1121, and kept up there until the early part of 1155. It has several Peterborough interpolations in the earlier sections. It is the version that was continued longest, and it includes a famous account of the anarchy of Stephen's reign.

The F version (Cott. Domit. A viii) is an abridgment, in both Old English and Latin, made in the late 11th or early 12th century, based on the archetype of E, but with some entries from A. It extends to 1058. Finally, the fragment H (Cott. Domit. A ix) deals with 1113–14 and is independent of E, the only other version to continue so late.

Anglo-Saxon language: *see* Old English language.

Anglo-Saxon law, the body of legal principles that prevailed in England from the 6th century until the Norman Conquest (1066) and after. In conjunction with Scandinavian law and the so-called barbarian laws (*leges barbarorum*) of continental Europe, it made up the body of law called Germanic law. Anglo-Saxon law was written in the vernacular and was relatively free of the Roman influence found in continental laws that were written in Latin. Roman influence on Anglo-Saxon law was indirect and exerted primarily through

the church. There was a definite Scandinavian influence upon Anglo-Saxon law as a result of the Viking invasions of the 8th and 9th centuries. Only with the Norman Conquest did Roman law, as embodied in Frankish law, make its influence felt on the laws of England.

Anglo-Saxon law was made up of three components: the laws and collections promulgated by the king, authoritative statements of custom such as those found in the Norman-instituted Domesday Book, and private compilations of legal rules and enactments. The primary emphasis was on criminal law rather than on private law, although certain material dealt with problems of public administration, with public order, and with ecclesiastical matters.

Before the 10th century, the codes often merely presented lists of compositions—money paid to an injured party or his family—but by the 10th century a new penal system had evolved, based on outlawry (declaring a criminal an outlaw), confiscation, and corporal and capital punishment. By this time there had also been an increased development of the law relating to administrative and police functions.

The Anglo-Saxon legal system rested on the fundamental opposition between folkright and privilege. Folkright is the aggregate of rules, whether formulated or not, that can be appealed to as an expression of the juridical consciousness of the people at large or of the communities of which it is composed. It is tribal in its origin, and it is differentiated on highly localized bases. Thus there was a folkright of East and West Saxons, Mercians, Northumbrians, Danes, and Welshmen, and these main folkright divisions persisted even after the tribal kingdoms disappeared in the 8th and 9th centuries. The responsibility for the formulation and application of the folkright rested, in the 10th and 11th centuries, with the local shire moots (assemblies); the national council of the realm (*see* witan) only occasionally used folkright ideas. The older laws of real property, succession, contracts, and compositions were mainly regulated by folkright; the law had to be declared and applied by the people themselves in their communities.

Folkright could, however, be broken or modified by special enactment or grant, and the foundation of such privileges was royal power. In this manner a privileged land tenure was created; the rules pertaining to the succession of kinsmen were replaced by concessions of testamentary power and confirmations of grants and wills; and special privileges as to levying fines were conferred. In time the rights originating in the royal grants of privilege came to outweigh folkright in many respects and were the starting point for the feudal system.

Before the 10th century a man's actions were considered not as exertions of his individual will but as acts of his kinship group. Personal protection and revenge, oaths, marriage, wardship, and succession were all regulated by the law of kinship. What began as a natural alliance later became a means of enforcing responsibility and keeping lawless individuals in order. As the associations proved insufficient, other collective bodies, such as guilds and townships, assumed their responsibilities. In the period before the Norman Conquest, much regulation was formalized by the king's legislation in order to protect the individual. In the area of property, for example, witnesses were required at cattle sales, not to validate the sale but as protection against later claims on the cattle. Some ordinances required the presence of witnesses for all sales outside of the town gate, and others simply prohibited sales except in town, again for the buyer's protection.

The preservation of peace was an important feature of Anglo-Saxon law. Peace was thought of as the rule of an authority within a

specific region. Because the ultimate authority was the king, there was a gradual evolution of stringent rules and regulations against violating the king's peace.

Angmagssalik (Greenland): *see* Ammassalik.

Ango, Jean (b. c. 1480, Dieppe, Fr.—d. 1551, Dieppe), French shipowner who, succeeding to his father's import-export business, eventually controlled, by himself or in association with others, a fleet of 70 ships.

By means of his extensive fleet of commerce vessels, Ango was able, in Francis I's reign, to ensure representation for France in maritime exploration. In 1524 he equipped the *Dauphine*, in which Giovanni da Verrazzano explored the east coast of North America and discovered the site of the future New York City. Jean and Raoul Parmentier in 1529 reached the coast of Sumatra in two of Ango's ships, the *Pensée* and the *Sacre*.

Ango also sponsored privateering. One of his captains, Jean Fleury, seized three ships carrying Aztec treasures from Mexico to Spain in 1523. Francis I, who generally upheld Ango, borrowed his ships for use against Spain and England. In 1530 Francis authorized Ango to raid Portuguese shipping to compensate for losses sustained at Portuguese hands. Alarmed, the Portuguese ambassador came to terms with Francis.

On the king's death, Ango became a victim of rivals and was imprisoned for a time in 1549 on a charge of official misconduct.

Angol, capital of Malleco *provincia*, Araucania *región*, southern Chile. Angol is situated on the Rehue River near its confluence with the Malleco River, in the southern portion of the fertile Central Valley. It was founded in 1862 on the site of a former Araucanian Indian outpost. The valley produces fruits (especially apples and wine grapes), wheat, oats, and cattle. Angol's industries include flour milling, brewing, tanning, and lumbering. Pop. (1999 est.) 45,000.

Angola, officially REPUBLIC OF ANGOLA, Portuguese REPÚBLICA DE ANGOLA, country on the southwest coast of Africa. It extends about 800 miles (nearly 1,300 km) from north to south and averages about 675 miles (1,100 km) from east to west. Angola's northernmost section of coastland, the Cabinda enclave, is located along the Atlantic coast just north of

Angola

Angola's border with the Democratic Republic of the Congo (Congo [Kinshasa]; formerly Zaire). Angola is bordered to the far northwest by the Republic of the Congo (Congo [Brazzaville]), to the north and northeast by Congo (Kinshasa), to the southeast by Zambia, to the south by Namibia, and to the west by the Atlantic Ocean. There are 1,025 miles (1,650 km) of coast, and the land frontiers total 3,023 miles (4,865 km). The capital is Luanda. Area 481,354 square miles (1,246,700 square km). Pop. (2000 est.) 10,145,000.

A brief treatment of Angola follows. For full

treatment, *see* MACROPAEDIA: Southern Africa.

For current history and for statistics on society and economy, *see* BRITANNICA BOOK OF THE YEAR.

The land. Angola may be divided into three major physiographic regions. The narrow coastal plain varies in width from about 125 miles (200 km) in the north to about 15 miles in the south. From this plain the land rises in a series of escarpments to a group of rugged highlands, the largest of which is the Bié (Angolan) Plateau, which covers about one-tenth of the country and rises to elevations between 5,000 and 8,600 feet (1,525 and 2,625 m). North of the Bié Plateau are the lower and less extensive Malanje highlands, while to the south the Huila Plateau rises steeply to about 7,700 feet. East of the highlands region is a huge, almost featureless plateau that covers about two-thirds of the country and gradually falls to an elevation of between 1,650 and 3,300 feet.

The highland plateaus separate Angola into three distinct drainage systems: one in the northeast drains northward into the great Congo River basin, while another, in the southeastern sector, drains eastward into the Zambezi system and southeastward into the interior drainage system of the Okavango River basin. The remaining drainage, westward into the Atlantic, provides most of Angola's hydroelectric power. The Cambambe Dam on the Kwanza River, southeast of Luanda, provides much of the country's hydroelectric power.

Angola's rainfall patterns vary dramatically from southwest to northeast. Annual precipitation increases from negligible along the southwestern coastal desert (a continuation of Namibia's Namib desert), where the cold Benguela Current adversely affects rainfall along much of the southern African coastline, to more than 40 inches (1,000 mm) throughout much of the northeastern third of the country, and to more than 70 inches (1,780 mm) in the extreme northeast and in Cabinda. The rainy season in the north (September to May) is much longer than it is in the south (December to March). Temperatures vary little by season, and the variation by elevation is slight—from a cool 60° F (16° C) in the highlands to 79° F (26° C) in Soyo in the north.

Of Angola's total land area, about 40 percent is forests and woodlands, the densest forests lying in the northwest (especially in Cabinda); all other areas, other than the desert southwest, have at least some scattered woodlands. Less than 10 percent of the land is arable, and that lies mostly in the south and west. Wildlife is abundant through much of Angola, but many species are endangered by human encroachment; among these are the African elephant, the black rhinoceros, the giant sable antelope, and the Angolan giraffe.

Angola has substantial petroleum reserves (about 3 percent of total African reserves) and natural-gas deposits and is also a major producer of diamonds. Other mineral resources include iron ore, manganese, copper, and phosphates. The country's hydroelectric potential is among the greatest in Africa, and timber reserves are also significant. The cold Benguela Current off the western coast provides rich fishing grounds.

The people. Angola's population is made up mostly of Bantu-speaking peoples. The main ethnic groups are the Ovimbundu, who make up more than one-third of the country's total population and speak Umbundu, and the Mbundu, who make up about one-fifth of the population and speak Kimbundu. Other major groups are the Kongo, Luimbe-Nganguela, Nyaneka-Humbc, Chokwe, and Luvale. The Khoisan-speaking San (Bushmen) are largely found scattered in isolated refuge areas in southeastern Angola. Although many indigenous languages and their dialects

arc spoken, Portuguese is the official language of Angola.

Traditional religions are giving way to Christianity and syncretic Afro-Christian sects; a majority of Christians are Roman Catholics.

Angola's birth and death rates are among the highest in Africa. More than two-fifths of the population is younger than 15 years of age. About one-third of the population is urban. Luanda is the largest city in Angola; other major towns are Huambo, Benguela, and Lobito.

With the Portuguese withdrawal in 1975, a large proportion of Angola's white population fled the country. More than 300,000 Portuguese nationals returned to Portugal. The civil war that persisted after that time led to large-scale relocations of the population. There was general movement from the cities to rural areas.

The economy. Angola has a mixed economy that is based largely upon agriculture, the extraction of petroleum, and other mineral resources. The gross national product (GNP) per capita remained relatively low for a developing African country during the 1980s and into the '90s, primarily because of the protracted civil war. Mining produces about half of the gross domestic product (GDP); petroleum and diamonds are the two chief products.

More than two-thirds of the total labour force is engaged in agriculture, which produces only one-eighth of the GDP. Food crops grown include tuberous crops (cassava and sweet potatoes), corn (maize), and pulses (primarily dry beans). Most remaining cropland is devoted to cash crops such as coffee, cotton, sisal, palm products, sugarcane, and tobacco. The principal livestock raised include cattle, goats, pigs, and sheep. Forest produce includes roundwood, all of it from broad-leaved species, and much of this is used for fuel. Before independence Angola had a large fishing industry, which continued during the civil war, though the catch was reduced significantly as fish stocks declined.

Most of the country's larger industries have been nationalized. The manufacturing sector produces processed foods, refined petroleum, footwear, and beverages. During the 1980s Angola borrowed funds from the Soviet Union, the African Development Bank, and other international financial sources to spur its economic development. At first, revenues from petroleum exports enabled the country to balance its budget and foreign-trade accounts. The costly civil and border wars, however, hindered its economic development, and the country's industrial sector remains small.

Angola's budgetary revenue is derived mostly from taxes and state returns from mixed enterprises. Expenditures are for defense, administration, education, health, and energy. Banks were nationalized in 1976.

The country's national railway network extends in three principal east-west lines, but its operations were severely curtailed during the civil war. About one-fourth of the road network is paved. Angola has one international airport, at Luanda, and a number of smaller domestic airfields. TAAG (Linha Aérea de Angola) is the national airline, providing both internal and international service. There are three principal ports (Luanda, Lobito, and Namibe), as well as several minor ones.

Angola's exports consist of crude oil and refined petroleum products, diamonds, and liquefied petroleum gas. Imports include raw materials, transport equipment, foodstuffs, medicines, and metals. The country's principal trading partners are the United States, Portugal, China, and France.

Government and social conditions. Angola's political system was in a state of transition in

the early 21st century. For almost three decades after reaching independence in 1975, Angola was wracked by a civil war between the Popular Liberation Movement of Angola (MPLA), which was the national government, and the National Union for the Total Independence of Angola (UNITA), which opposed the MPLA. The MPLA ruled Angola as a one-party Marxist state and favoured central planning in its economic policies. A peace accord reached between the MPLA and UNITA in 1991 allowed national elections to take place in 1992. The MPLA softened its commitment to Marxism and led a caretaker government for Angola until the September 1992 elections, in which it won a majority of parliamentary seats in the National Assembly.

Educational and health-care services in Angola were disrupted by civil war and a shortage of trained personnel. Mass-immunization campaigns have been undertaken against endemic tropical and other common diseases, but there is widespread malnutrition, and infant mortality is high. Life expectancy in Angola stands at only 45 years for men and 48 years for women. Free education is provided by the government, but compulsory education extends only to primary schoolchildren. Only a little more than two-fifths of the population over age 15 is literate. The University Agostinho Neto in Luanda was founded in 1962.

Although the country has several daily newspapers, many people gain their news from wall newspapers. Angola also has radio and television broadcasting services. Though increasingly overlaid by Western influences, traditional means of cultural expression persist. There is a rich oral literature, and sculpture in wood, ivory, clay, and copper is created.

History. The original inhabitants of what is now Angola were probably Khoisan-speaking hunters and gatherers. During the 1st millennium AD, large-scale Bantu-speaking migrations (possibly originating in central Africa) into southern Africa absorbed the older population and introduced, or at least expanded, iron technology and cereal cultivation in the area. Eventually, they came to constitute the dominant ethnolinguistic group of southern Africa. Their occupation of the area that is now Angola was complete by 1600.

The most important Bantu kingdom in Angola was the Kongo, with its capital at Mbanza Kongo, called by the Portuguese São Salvador do Congo. This kingdom was a highly centralized and complex state that was divided into six provinces. South of the Kongo was the Ndongo kingdom of the Mbundu people. It was equally centralized and gave Angola its name from the title for its king, the *ngola*.

In 1483 Portuguese explorers reached Angola, Christianizing the ruling family of the Kongo, and engaged in trade and missionary work. However, increasing Portuguese involvement in the slave trade eventually turned the Kongo against Portugal, which in turn led to Portugal's destruction of the Ndongo kingdom to the south. Portugal's colonization of the area was slow, but its slave trade flourished, so much so that by the early 17th century some 5,000 to 10,000 slaves were being exported annually from Luanda.

The boundaries of Angola were not firmly fixed until 1926, when a dispute with South West Africa (now Namibia) was settled. Other boundaries had been fixed in the 1890s. Armed resistance within Angola against colonial rule continued until 1930. Under Portuguese rule economic opportunities for Africans were minimal, forced-labour practices were common, and all economic development was directed toward Portugal's benefit.

Nationalist movements began in earnest in the 1950s. The MPLA, a Marxist-oriented party whose main base of support was in Lu-

anda and among the Mbundu people, became a dominant force in the Angolan fight for independence, but other groups developed, based on ethnic, regional, and ideological lines. Fighting intensified in the 1960s and '70s, and the Portuguese finally withdrew from Angola in 1975. Interparty struggles within Angola, however, resulted in civil war after Portugal's departure. The MPLA, with Soviet and Cuban assistance, seized control of most of Angola, but sporadic fighting continued with UNITA, a Western-supported guerrilla organization whose main base of support was the Ovimbundu people. The MPLA maintained control of the capital, Luanda, and the coastal and oil-producing areas, while UNITA controlled most of eastern and southern Angola. The war dragged on until 1991 when the MPLA and UNITA made peace with each other at the behest of the Soviet Union and the United States; free, multiparty elections were held in Angola in 1992 under international supervision. Alleging fraud, UNITA refused to accept the results of the election, which the MPLA won. Violence ensued until the government and UNITA signed the Lusaka peace accord in 1994. The agreement was routinely violated even as discussions continued between the two sides because UNITA's intransigent leader Jonas Savimbi was able to fund his party's ongoing resistance through the sale of diamonds. Savimbi was killed by government forces in February 2002; a peace agreement was signed in April, and the civil war was officially

first

Angora goat, breed of domestic goat originating in ancient times in the district of Angora in Asia Minor. The goat's silky coat yields the mohair of commerce. The Angora had been widely but unsuccessfully imported into Europe by the mid-18th century, but not until the animal was established in South Africa a century later did the Western mohair industry develop. Importation of the Angora goat to the United States followed shortly, with development centring in Texas and the Southwest.

The Angora is generally smaller than other

goulême from the 9th century. Fought over by the French and English in the Hundred Years' War, it also suffered in the religious wars of the late 16th century.

Angoulême's 19th-century town hall occupies the site of the counts' château (birthplace of Margaret of Angoulême), of which two towers, the Valois (15th century) and the Lusignan (13th century), remain. The Cathedral of Saint-Pierre (1105–28; restored 19th century) is a domed Romanesque-Byzantine structure whose elaborate facade, enriched with Romanesque sculpture, contrasts sharply with the stark, aisleless interior. Angoulême's old city ramparts have been razed to make way for boulevards with extensive views. The Land of Angoulême was the name given to the site of present-day New York City in 1524 by Giovanni da Verrazano, who discovered the harbour while serving King Francis I, who was also count of Angoulême.

The city's diversified industries, mostly located in the surrounding suburbs, includes papermaking and the manufacture of felt, iron, jewelry, bricks, and refrigerators. Pop. (1999) 43,171.

Angoulême DYNASTY (reigned 1515–74), a branch of the Valois dynasty (*q.v.*) in France.

Angoulême, Charles de Valois, duc (duke) d' (b. April 28, 1573, Fayet, France—d. Sept. 24, 1650, Paris), illegitimate son of King Charles IX of France and Marie Touchet, chiefly remembered for his intrigues against King Henry IV and for his later military exploits, particularly as commander at the siege of La Rochelle in 1627.

Received favourably at the French court as a youth because of his ready wit and good looks, Charles was granted the title of comte d'Auvergne and was made colonel general of the cavalry. He served Henry IV during the religious strife of the period in his campaigns against the Catholic League, but, after Queen Margaret successfully contested his right to Auvergne, he took part in a series of conspiracies against the crown.

Pardoned for his part in the Marshal de Biron's conspiracy of 1601, he began to engage in more treasonable plots with Spain (1604) in concert with his half sister, Henriette d'Entragues, mistress of Henry IV. Soon he went into open rebellion; after his capture in 1605 he was condemned to life imprisonment. Released in 1616 to serve the Marshal d'Ancre, he was created duc d'Angoulême in 1619. The Cardinal de Richelieu gave him military commands against the Protestants at the sieges of Montauban (1621) and of La Rochelle (1627) and in Lorraine (1635). Cardinal Mazarin gave him a command in the north in 1643. Angoulême's *Mémoires*, first published in 1667, were reprinted in the Michaud-Poujoulat collection (1836).

Angoulême, Louis-Antoine de Bourbon, duc (duke) d' (b. Aug. 6, 1775, Versailles, France—d. June 3, 1844, Gorizia, Venetia, Austrian Empire [now in Italy]), last dauphin of France and a prominent figure in the restoration of the Bourbon line after the defeat of Napoleon in 1814.

Angoulême was the elder son of the comte d'Artois (afterward Charles X of France) and Marie Thérèse of Savoy. When the revolution broke out in 1789, he left France with his father. In 1799 he married his cousin Marie Thérèse Charlotte, the daughter of Louis XVI and Marie-Antoinette. After living in Poland and England, Angoulême returned to France in 1814 and with British help raised the royal standard again at Bordeaux. As chief of the royalist army in the southern Rhône River valley, he was unable to prevent Napoleon's return to Paris. After Waterloo and the sec-

Angoumois, former province of France, nearly corresponding to the modern *département* of Charente, that represented the possessions of the counts of Angoulême from

The province of Angoumois

the 10th to the 12th century. Long part of Aquitaine, it was recovered by France from the English in 1373. Henry IV subordinated it to the *gouvernement* of Orléanais, and under Louis XIV it was made part of a joint *gouvernement* of Saintonge and Angoumois.

Angra do Heroísmo, also called ANGRA, city on the south coast of Terceira, an island of the Portuguese Azores archipelago in the North Atlantic. It lies at the base of Mount Brasil. Angra became a city in 1534. The words *do heroísmo* commemorate the island's resistance to invading Spaniards in 1580–82. It was the capital of the Azores from 1766

Angra do Heroísmo, Terceira Island, Azores
Walter Imber

to 1832 and is still the see of the Azorean diocese. Its fortresses include the 17th-century São João Baptista (on Mount Brasil), São Sebastião, and a 17th-century citadel. A major earthquake in 1980 severely damaged many structures on Terceira but left the North Atlantic Treaty Organization (NATO) military air base at Lajes relatively unscathed. Pop. (1991 prelim.) 11,672.

Angra dos Reis, city, southwestern Rio de Janeiro *estado* ("state"), eastern Brazil. It lies on Ilha Grande Bay, an inlet of the Atlantic. The city's income derives from its port operations, a sizable fishing industry, and the cultivation of bananas in the agricultural hinterland. A railway running from Barra Mansa transports sugar, coffee, *feijão* (beans), steel, and coal to Angra dos Reis for export. Since the development of the city of Volta Redonda, 35 miles (56 km) inland, with its huge steel-mill complex, the shipbuilding and port facilities of Angra dos Reis have gained added

importance. A nuclear power plant has also been built near Angra dos Reis. The city is on the Rio de Janeiro–Santos highway. Surviving colonial buildings include the 17th-century Church of Our Lady of Mount Carmel. Pop. (1991 prelim.) 28,515.

Angra Pequena (Namibia): *see* Lüderitz.

Angren, city, eastern Uzbekistan. It lies on the left bank of the Ohangaron River, 70 miles (115 km) east of Tashkent. The centre of the Uzbekistan coal industry, it was created in 1946 from mining settlements that had grown up in the rich Angren coal basin during World War II; it still consists of disconnected settlements. Angren has a large power station, a large construction-materials industry, and a rubber-fabricating plant. A teacher-training institute and a museum are located in the city. Pop. (1992 est.) 133,000.

Angrezābād (India): *see* English Bāzār.

Angry Young Men, various British novelists and playwrights who emerged in the 1950s and expressed scorn and disaffection with the established sociopolitical order of their country. Their impatience and resentment were especially aroused by what they perceived as the hypocrisy and mediocrity of the upper and middle classes.

The Angry Young Men were a new breed of intellectuals who were mostly of working class or of lower middle-class origin. Some had been educated at the postwar red-brick universities at the state's expense, though a few were from Oxford. They shared an outspoken irreverence for the British class system, its traditional network of pedigreed families, and the elitist Oxford and Cambridge universities. They showed an equally uninhibited disdain for the drabness of the postwar welfare state, and their writings frequently expressed raw anger and frustration as the postwar reforms failed to meet exalted aspirations for genuine change.

The trend that was evident in John Wain's novel *Hurry on Down* (1953) and in *Lucky Jim* (1954) by Kingsley Amis was crystallized in 1956 in the play *Look Back in Anger*, which became the representative work of the movement. When the Royal Court Theatre's press agent described the play's 26-year-old author John Osborne as an "angry young man," the name was extended to all his contemporaries who expressed rage at the persistence of class distinctions, pride in their lower-class mannerisms, and dislike for anything highbrow or "phoney." When Sir Laurence Olivier played the leading role in Osborne's second play, *The Entertainer* (1957), the Angry Young Men were acknowledged as the dominant literary force of the decade.

Their novels and plays typically feature a rootless, lower-middle or working-class male protagonist who views society with scorn and sardonic humour and may have conflicts with authority but who is nevertheless preoccupied with the quest for upward mobility.

Among the other writers embraced in the term are the novelists John Braine (*Room at the Top*, 1957) and Alan Sillitoe (*Saturday Night and Sunday Morning*, 1958) and the playwrights Bernard Kops (*The Hamlet of Stepney Green*, 1956) and Arnold Wesker (*Chicken Soup with Barley*, 1958). Like that of the Beat movement in the United States, the impetus of the movement was exhausted in the early 1960s.

angstrom, unit of length used chiefly in measuring wavelengths of light, equal to 10^{-10} metre. It is named for the 19th-century Swedish physicist Anders Jonas Ångström. The symbol is Å. The angstrom and multiples of it, the micron and the millimicron, are also used to

ond restoration of Louis XVIII, Angoulême served Louis loyally. During the reign of his father, Charles X, he worked to rid the army of former imperial officers and commanded the French expedition that helped quell an anti-Bourbon revolt in Spain (1823). In 1830, when Charles was compelled to abdicate, Angoulême renounced his claim to the throne and went into exile.

measure such quantities as molecular diameters and the thickness of films on liquids.

Ångström, Anders Jonas (b. Aug. 13, 1814, Lögdö, Swed.—d. June 21, 1874, Uppsala), Swedish physicist, a founder of spectroscopy for whom the angstrom, a unit of length equal to 10^{-10} metre, was named.

Educated at the University of Uppsala, Ångström became privatdocent (lecturer) there in 1839 and succeeded to the chairmanship of the physics department in 1858. In 1843 he became observer at Uppsala Observatory.

Ångström's most important work concerned heat conduction and spectroscopy. He devised a method of measuring thermal conductivity, showing it to be proportional to electrical conductivity. In 1853 he pointed out that the electric spark yields two superposed spectra, one from the metal of the electrode and the other from the gas through which it passes. From Euler's resonance theory Ångström deduced a principle of spectrum analysis: that an incandescent gas emits rays of the same refrangibility as those it can absorb.

Ångström's studies of the solar spectrum led to his discovery, announced in 1862, that hydrogen is present in the Sun's atmosphere.

Anders Jonas Ångström, c. 1865
By courtesy of the Kungl. Biblioteket, Stockholm

In 1868 was published his great map of the normal solar spectrum, which long remained authoritative. He was the first, in 1867, to examine the spectrum of the Aurora Borealis and to detect and measure the characteristic bright line in its yellow-green region, but he was mistaken in supposing that this same line is also to be seen in the zodiacal light.

Ångström's son Knut Johan Ångström was also a physicist who worked in spectroscopy and taught at the University of Uppsala.

Anguier, François; and Anguier, Michel-André (respectively, b. c. 1604, Eu, Fr.—d. Aug. 9, 1669, Paris; b. c. 1613, Eu—d. July 11, 1686, Paris), French sculptors who produced decorations for tombs, churches, palaces, and public monuments.

Beginning their training in France, they went in about 1641 to Rome, where they studied in the workshop of the Baroque sculptor Alessandro Algardi (François until 1643 and Michel-André until 1651). The brothers collaborated between 1648 and 1652 on a tomb for Henri II, Duke de Montmorency, at Moulins.

François's most characteristic work is the funerary statue of Gasparde de la Châtre, second wife of the historian Jacques de Thou, in the Louvre, Paris. Michel-André was employed in the decoration of Anne of Austria's apartments in the Louvre, modeled on Pietro da Cortona's decorations in the Pitti Palace in Florence. Michel-André worked at Vaux-le-Vicomte—the château of Louis XIV's minister Nicolas Fouquet, near Melun—with Charles Le Brun and André Le Nôtre. His most important commission, completed in 1667, was the decoration of the Church of Val-de-Grâce in Paris, to which he contributed reliefs and

a marble nativity group for the high altar (1665), now in the Church of Saint-Roch in Paris. His reliefs for the triumphal arch of the Porte Saint-Denis, executed in a severely classical style, were completed in 1674.

Anguilla, island, a dependent territory of the United Kingdom, in the eastern Caribbean Sea. The most northerly of the Leeward Islands in the Lesser Antilles, its territory includes nearby Scrub, Seal, Dog, and Sombrero

Anguilla

islands and Prickly Pear Cays. Saint Martin lies 5 miles (8 km) to the south and St. Kitts (St. Christopher) about 60 miles (100 km) to the southeast. The land area of Anguilla covers about 35 square miles (91 square km). The chief town, near the centre of the island, is The Valley. The population in 1990 was estimated to be 7,300.

For information about regional aspects of Anguilla, see MACROPAEDIA: West Indies.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

The land. Anguilla is a relatively flat, coral and limestone island covered with sparse, dry woodlands and fringed by white sand beaches. Numerous bays and inlets indent the shoreline. Its shape is long (16 miles [26 km]) and narrow (3.5 miles [6 km]), giving rise to its name (French: *anguille*, "eel"). The highest elevation is about 213 feet (65 m), at Crocus Hill. There are some stretches of fertile soil on the island, but most of the land is suitable only for grazing. Anguilla has no rivers. There are a few salt ponds, however, which provide some commercial quantities of salt. The tropical climate is sunny and dry most of the year. Temperatures average about 80° F (27° C) throughout the year, and rainfall amounts to about 35 inches (900 mm) annually. The wettest period is usually from September to January. Hurricanes, which usually occur from July to October, sometimes strike with damaging force.

The people. Most of the people of Anguilla are blacks and mulattoes, the descendants of African slaves. The few white inhabitants are mostly of European descent. The official language is English, and the largest religious memberships are in the Protestant denominations (Anglican and Methodist). The island's

Harbour and new road, Anguilla
Bradley Smith, New York

population is young, more than one-third of the people being less than 15 years of age. The Anguillan birth and death rates are moderate.

The economy. Anguilla's dry climate and its unsuitable soil limit the importance of agriculture in the economy. The chief crops grown are pigeon peas, corn (maize), and sweet potatoes. Domestic animals raised include sheep, goats, pigs, cattle, and poultry. There is a government-run cattle-breeding service, and some livestock is exported. The island's economy traditionally has been more dependent upon fishing as a source of revenue. The offshore reefs abound with fish and lobster, providing one of the island's main sources of foreign exchange. Lobster is exported to nearby islands and to the United States. Salt, obtained by natural evaporation from Anguilla's salt ponds, is also produced in exportable quantities. The island's marine life and white sand beaches, considered to be among the finest in the Caribbean, are the basis of a growing tourist industry that is beginning to dominate the economy. The development of hotels and other tourist facilities is important in Anguilla's economic planning. Some foreign exchange also comes from islanders who work abroad and send money back to their families on Anguilla.

About half of the island's roads are paved. Road Bay and Blowing Point are the main seaports, and there is an airport at Wallblake.

Government and social conditions. Anguilla is governed under a constitution that became effective in 1982 and that gave it considerable control over internal affairs. Executive power is vested in a governor, who is appointed by the monarch of the United Kingdom. The governor is advised in the execution of his duties by an executive council made up of a chief minister, three other ministers, and two ex-officio members. The legislative branch is the House of Assembly, some of whose members are elected.

Anguillans live under rather poor conditions, and employment is unsteady. Nevertheless, housing conditions are good compared with the general standard of Caribbean islands. Most houses are built of concrete and are relatively spacious in design. The general health of the islanders is good; they are served by a cottage hospital and have access to a limited range of health services. Education between the ages of 5 and 14 is free and compulsory; it is provided by the government's elementary schools and a secondary school. Advanced training and education is available at schools elsewhere in the Caribbean region. The government owns and operates a radio broadcasting station, and a modern internal telephone system connects all parts of the island.

History. Anguilla does not seem to have been a stronghold of the Carib Indians for any length of time, and it is uncertain whether or not the island was visited by Columbus. It was first colonized in 1650 by English settlers coming from St. Christopher and has remained a British territory ever since. The island was attacked in 1688 by a party of Irishmen who eventually settled there and whose surnames are still in evidence. Anguilla was attacked twice by the French in the 18th century (1745 and 1796), but they were repelled.

The territory was administered by the British as part of the Leeward Islands after colonization, and from 1825 it was closely associated with St. Christopher, a situation it protested. In 1875 Anguilla petitioned for separate status but was rejected. St. Christopher, Nevis, and Anguilla were united as a single colony in 1882. From 1958 until 1962 the islands were a unit of the Federation of the West Indies. Opposition to rule from St. Christopher continued into the 1960s, reaching a climax in 1967, when the associated state of St. Christopher-Nevis-Anguilla was formed. In reaction, Anguilla ejected the St. Christopher police, set up its own council, and subsequently pro-

claimed its independence. After negotiations failed, the British intervened in March 1969 to restore legal government with troops and a temporary British commissioner. The troops were withdrawn in September 1969, and the Anguilla Act (July 1971) placed the island directly under British control. A new constitution in 1976 provided a large measure of internal autonomy under the crown, while formally retaining Anguilla as part of the associated state. On Dec. 19, 1980, Anguilla was formally separated from St. Christopher and Nevis, and in 1982 a new Anguillan constitution became operative.

anguilliform, any of the bony fishes that contains more than 500 species of eel (*q.v.*).

angular harp, musical instrument in which the neck forms a clear angle with the resonator, or belly; it is one of the principal varieties of the harp. The earliest-known depictions of angular harps are from Mesopotamia about 2000 bc. In Egypt, especially, and in Mesopotamia, this harp was played vertically, held with the

neck at the lower end, and plucked with the fingers of both hands. In Mesopotamia it was sometimes also placed horizontally across the player's lap, strings toward him, the strings swept with a plectrum as the left hand damped unnecessary strings.

The pre-Islamic Persian reliefs at Tāq-e Bostān (c. AD 600) contain both the latest-known depiction of a horizontal angular harp and the earliest representation of the medieval angular harp of Persia (*chang*) and Arabic-speaking countries (*junk*). Placed with the neck near the floor and played by a kneeling musician, the medieval angular harp survived until the 16th century in Egypt, the 17th century in Turkey, and the 19th century in Persia.

angular momentum, property characterizing the rotary inertia of an object or system of objects in motion about an axis that may or may not pass through the object or system. The Earth has orbital angular momentum by reason of its annual revolution about the Sun

and spin angular momentum because of its daily rotation about its axis. Angular momentum is a vector quantity, requiring the specification of both a magnitude and a direction for its complete description. The magnitude of the angular momentum of an orbiting object is equal to its linear momentum (product of its mass m and linear velocity v) times the perpendicular distance r from the centre of rotation to a line drawn in the direction of its instantaneous motion and passing through the object's centre of gravity, or simply mvr . For a spinning object, on the other hand, the angular momentum must be considered as the summation of the quantity mvr for all the particles composing the object. Angular momentum may be formulated equivalently as the product of I , the moment of inertia (*q.v.*), and ω , the angular velocity (*q.v.*), of a rotating body or system, or simply $I\omega$. The direction of the angular-momentum vector is that of the axis of rotation of the given object and is designated as positive in the direction that a right-hand screw would advance if turned similarly. Appropriate MKS or SI units for angular momentum are kilogram metres squared per second ($\text{kg}\cdot\text{m}^2/\text{sec}$).

For a given object or system isolated from external forces, the total angular momentum is a constant, a fact that is known as the law of conservation of angular momentum. A rigid spinning object, for example, continues to spin at a constant rate and with a fixed orientation unless influenced by the application of an external torque. (The rate of change of the angular momentum is, in fact, equal to the applied torque.) A figure skater spins faster, or has a greater angular velocity ω , when the arms are drawn inward, because this action reduces the moment of inertia I while the product $I\omega$, the skater's angular momentum, remains constant. Because of the conservation of direction as well as magnitude, a spinning gyrocompass in an airplane remains fixed in its orientation, independent of the motion of the airplane.

For the extension of the conception of orbital and spin angular momentum to analogous properties of subatomic particles such as electrons, see spin. See also momentum.

angular velocity, time rate at which an object rotates, or revolves, about an axis, or at which the angular displacement between two bodies changes. In the Figure, this displacement is represented by the angle θ between a line on one body and a line on the other.

In engineering, angles or angular displacements are commonly expressed in degrees or revolutions (of 360°), and angular velocities in revolutions per minute (rpm). In mathematics and physics, angles are usually expressed in radians and angular velocities in radians per second. These measures are related through the following conversion factors: 1 degree equals $\pi/180$ (about 0.0175) radian; 1 rpm equals $\pi/30$ (about 0.105) radian per second.

Angular displacement

In many situations, an angular velocity—usually symbolized by the Greek letter omega (ω)—is equally well regarded as a frequency (*q.v.*), and the choice of terms depends upon the particular aspect of a system being considered. Thus, in electrical engineering, the rotational speed of a generator might be expressed in revolutions per minute, whereas the

alternating electric current produced by the generator would be described in terms of its frequency.

The angular acceleration is the time rate of change of the angular velocity and is usually designated by a and expressed in radians per second per second. For the case in which the angular velocity is uniform (nonvarying), $\theta = \omega t$ and $a = 0$. If a is uniform but not zero, $\omega = at$ and $\theta = \frac{1}{2}at^2$.

Where the same name may denote a person, place, or thing, the articles will be found in that order

Angus, formerly FORFARSHIRE, former county in eastern Scotland, bounded on the east by the North Sea and on the south by the Firth of Tay. The county was abolished in the administrative reorganization of 1975 and is now largely in the district of Angus (*q.v.*). The chief city of the county was Dundee, which was subsequently excluded from the district of Angus.

The county of Angus was originally occupied by Picts. There are remains of Pictish hill forts at several locations in the area, notably at Finavon and on the Caterthuns near Menmuir. The Romans established temporary camps in the area in the 1st century AD, and traces of their camps and roads are still evident. From the 6th century AD on the Picts had to defend their land against Teutonic and Danish invaders from the sea and against Angles invading from Northumbria by land, and in the 11th century an invasion of Vikings was defeated. During the 12th century, colonies of Flemings established wool and linen industries in Angus, and the county consequently enjoyed a prosperity that was little affected by the Scottish Wars of Independence in the early 14th century. The county suffered more in the English Civil War in the 17th century, when both Dundee and the town of Brechin were sacked.

Angus, district, Tayside region, eastern Scotland. It was created by the reorganization of 1975 and covers most of the former county of Angus. The district has an area of 785 square miles (2,033 square km). Forfar, a textile-manufacturing town, is the seat of the district authority.

Angus is bisected roughly by the Highland Boundary Fault running northeast-southwest from Edzell to Lintrathen. The Highland area is composed of plateaus of 2,000–3,000 feet (600–900 m) dissected by three broad glens (Glen Isla, Glen Clova, and Glen Esk). The uplands were little eroded by glaciation except in the main valleys, in which glaciers excavated ribbon lochs (lakes)—e.g., Loch Lee in Glen Esk, now used as a reservoir. South of the impressive Highland edge lies the rich Vale of Strathmore (the Howe [hollow] of Angus), which has fertile glacial deposits. The Sidlaw Hills form the southeastern boundary of the Vale of Strathmore, and their scarp face looks southeastward over the coastal lowlands covered with till, unstratified rock material deposited by a glacier. Sand dunes and post-glacial raised beaches fringe the shore.

The climate is generally dry, with cool, dry springs and frequent sea mists. Late summer and early autumn are typically warm and dry, and there are long hours of sunshine, dictating a late harvest. Upland soils are thin and poor, with peat bogs in flatter areas. Light, well-drained soils occur on the fluvio-glacial and raised-beach sands, and fertile riverine clays surround the Montrose Basin. The lowlands are predominantly agricultural, except for the moorland crest of the Sidlaws and some woodland on the gravel soils.

The economy ranges from remote upland farms to complex industrial and port activities in Dundee to the tourist industry. The upland areas support extensive sheep farms, and beef cattle are intensively raised in the glens. About half of the land is cultivated; emphasis is on cereals, sugar beets, and fodder crops. High-grade seed potatoes are grown as a cash crop and exported. Smallholdings produce raspberries and strawberries for the jam-making industries of Dundee and Montrose.

Angus has an active industrial tradition in textile manufacture. Staple industries are the manufacture of jute and linen, especially in Dundee. Shipbuilding is also a long-established industry in Dundee and engineering in Arbroath. Diversification of industry in Dundee, the industrial and commercial centre, is reflected in its large, modern industrial estate. There is a thriving whitefish industry at Arbroath, and throughout the region are facilities for canning locally grown produce. Pop. (1989 est.) 95,080.

Angus, breed of black, polled beef cattle, for many years known as Aberdeen Angus, originating in northeastern Scotland. Its ancestry is obscure, though the breed appears closely related to the curly-coated Galloway, sometimes called the oldest breed in Britain. The breed was improved and the present type of the cattle fixed early in the 19th century by a number of constructive breeders among whom Hugh Watson and William McCombie were the most famous.

The characteristic features of the breed are black colour, polled head, compact and low-set body, fine quality of flesh, and high dressing percentage. The Angus is a beef breed of the highest rank, and for years purebred or crossbred Angus steers have held high places of honour at the leading fat-stock shows in Great Britain and the United States. This breed was introduced into the United States in 1873, and after that date its influence spread widely there and in other countries.

Within the breed, a strain known as Red Angus was gaining in popularity in the late 20th century, particularly for purposes of out-crossing and crossbreeding. The Brangus, developed from Brahman and Angus stocks, is notable for its resistance to heat.

Angus, EARLS OF, titled Scottish nobility of several creations, notably in the family Douglas, grouped below chronologically and indicated by the symbol ●.

● **Angus, Archibald Douglas, 6th Earl of** (b. c. 1489—d. January 1557, Tantallon Castle, East Lothian, Scot.), powerful Scottish lord during the reigns of King James V and Mary, Queen of Scots. He was the grandson of the 5th earl, Archibald Douglas (c. 1449—c. 1514).

By his second marriage in 1514 to the queen dowager Margaret Tudor, Angus aroused the jealousy of the nobles. Margaret was supplanted in 1515 as regent and guardian of the infant James V by the Duke of Albany and fled to England. On her return she found that Angus had formed a liaison with a daughter of the laird of Traquair, and she therefore allied with Albany against her husband. He was charged with high treason in 1522 and sent to France. But he returned two years later with the support of Henry VIII of England, entered Edinburgh in 1525, and called a parliament. He and the Douglasses then wielded supreme power until Margaret obtained a divorce and James V escaped from his stepfather's tutelage (1528), issuing a decree of forfeiture against him. Angus took refuge in England, and James took vengeance on his relations, burning at the stake (July 17, 1537) Angus' sister Janet, Lady Glamis.

After the death of James V in 1542, Angus returned to Scotland, and the act of forfeiture was annulled. He was commissioned to arrange a marriage between Mary Stuart and Prince Edward (afterward Edward VI of England), but his English sympathies were disappearing. He was appointed lieutenant of southern Scotland, defeated the English at Ancrum moor on Feb. 27, 1545, and led the vanguard when the Scots were defeated at Pinkie in 1547.

His was a career in which national interests were completely subordinated to those of his family. His only surviving legitimate child, by Margaret Tudor, was Margaret, who married Matthew, 4th Earl of Lennox, and became the mother of Lord Darnley, husband of Mary, Queen of Scots. He was succeeded by his nephew David Douglas (c. 1515—57).

● **Angus, Archibald Douglas, 8th Earl of, EARL OF MORTON** (b. 1555—d. Aug. 4, 1588, Smeaton, near Dalkeith, Midlothian, Scot.), Scottish rebel during the reign of James VI and a strong advocate of Presbyterian government. He was son of the 7th earl, who was nephew of the 6th, and he succeeded to the earldom at the age of two. The earldom of Morton came to him in 1586.

During the regency of his uncle, the Earl of Morton, he rose rapidly to power. He became privy councillor and sheriff of Berwick (1573), lieutenant general of south Scotland (1574), warden of the west marches and steward of Fife (1577), and lieutenant general of the whole realm (1578). But when Morton fell in 1581 Angus was declared guilty of high treason for supporting him and fled to London. After a brief reconciliation with James VI he joined the rebellion of the Earl of Mar and the master of Glamis, and sentence of attainder was pronounced against all three. The rebels fled to Newcastle, which became a centre of Presbyterianism and of projects against the Scottish government encouraged by Elizabeth I of England. They returned to Scotland in October 1584 and secured from James the restoration of their estates and a share in the government. Angus was appointed warden of the marches and lieutenant general on the border, but his support of Presbyterianism prevented his gaining real favour with the king.

● **Angus, William Douglas, 10th Earl of** (b. c. 1552—d. March 3, 1611, Paris, Fr.), Scottish rebel and conspirator, a convert to Roman Catholicism during the reign of James VI.

He joined the household of the Earl of Morton and then, while visiting the French court, became a Roman Catholic; in consequence, on his return, he was disinherited and placed under restraint. Nevertheless, he succeeded to his father's titles and estates in 1591, and, though in 1592 he was disgraced for his complicity in the Earl of Bothwell's plot, he was soon liberated and performed useful services as the king's lieutenant in the north of Scotland. In July 1592, however, he was asking for help from Elizabeth I of England in a plot against Sir John Maitland, the chancellor, and began intriguing also with Spain; and thus he was imprisoned (on the discovery of the treason) in Edinburgh Castle in January 1593. He succeeded on January 13 in escaping by the help of his countess, joining the earls of Huntly and Erroll in the north. They were offered an act of "oblivion" or "abolition" provided they renounced their religion or quit Scotland. Declining these conditions they were declared traitors and "forfeited." Huntly and Erroll were subdued by James VI himself in the north, and Angus failed in an attempt upon Edinburgh in concert with the Earl of Bothwell. Subsequently in 1597 they all renounced their religion, declared themselves Presbyterians, and were restored to their estates and honours.

Not long afterwards, however, Angus recanted and was again excommunicated in 1608. In 1609 he withdrew to France, and died in Paris. He was succeeded by his son William, as 11th Earl of Angus, afterward 1st Marquess of Douglas (1589—1660).

Anhalt, former German state, which was a duchy from 1863 to 1918 and a *Land* (state) until 1945, when it was merged in Saxony-Anhalt. Saxony-Anhalt was a *Land* of the German Democratic Republic from 1949 to 1952, when it was broken up into *Bezirke* (districts), the former territories of Anhalt being divided between the *Bezirke* of Magdeburg and of Halle. Upon the reunification of East and West Germany in 1990, Saxony-Anhalt was reconstituted a *Land* and included the former Magdeburg *Bezirk*, most of the former Halle *Bezirk*, and a small part of Cottbus *Bezirk*.

Territorially the duchy of Anhalt was divided into two major parts (the eastern one comprising Zerbst, Dessau, Köthen [Cöthen], and Bernburg, the western one being centred on Ballenstedt) and five smaller ones, all of them enclaves within the geographic boundaries of the Prussian province of Saxony.

The level country around the upper Elbe River from which Anhalt was constituted was in the 11th century still part of the duchy of Saxony. It was united in the 12th century in the possession of Albert I the Bear, margrave of Brandenburg, and was made a separate county in 1212 under Albert's grandson Henry, who in 1218 took the title *Fürst* (prince). When he died in 1252, his three sons divided the Anhalt lands among themselves, thus inaugurating the three lines of Aschersleben, Bernburg, and Zerbst. The Aschersleben line died out in 1315. The remainder existed as Anhalt-Dessau and Anhalt-Köthen in the 16th century, but, beginning in 1603, it was divided into four parts: Dessau, Bernburg, Zerbst, and Köthen. Zerbst was absorbed by the other three in 1793, and in 1806, when the Holy Roman Empire was dissolved, the three surviving princes each assumed the title of duke. In 1863 all of Anhalt was united under Leopold IV of Anhalt-Dessau.

Anhalt had become Protestant at the time of the Reformation, and, beginning in the 17th century, it came under Prussian influence. The reorganization of the Prussian army by Leopold I of Anhalt-Dessau in the early 18th century contributed to the later victories of Frederick II the Great. In 1807 the Anhalt dukes joined the Confederation of the Rhine set up by Napoleon and supported him until 1813. In 1815 they joined the German Confederation and in 1828 the Zollverein (Customs Union) organized by Prussia. In 1871 Anhalt became a state of the newly founded German Reich. Under the republican Weimar Constitution, adopted in 1919, Anhalt became a *Land* of the German Reich.

Anhava, Tuomas (b. June 5, 1927, Helsinki), Finnish poet and translator working within the modernist tradition of Ezra Pound and T.S. Eliot.

Anhava was a perfectionist in his poetry, with a fanatical concern for *le mot propre* and a great theoretical interest in the aesthetics of modern poetry. His *Runoja* (1953; "Poems") has as its central theme alienation and a search for a transcendence of everyday reality. These motifs are developed in the technically difficult poems of *36 runoja* (1958; "36 Poems"). The images in these poems are strongly reminiscent of the Japanese and Chinese poetry Anhava translated during the same period. The simplification and compression of Oriental epigrams is employed in *Runoja 1961* and *Kuudes kirja* (1966; "The Sixth Book"). Later works include *Runot 1951-1966* (1967) and *Valitut runot* (1976).

Even though Anhava never achieved great popularity, he had a great influence on many

young Finnish poets through his uncompromising search for aesthetic perfection.

Anheuser-Busch Companies, Inc., company that is the largest producer of beer in the United States and the world. It is headquartered in St. Louis, Mo.

The company had its origins in a small brewery opened in St. Louis by George Schneider in 1852. This faltering enterprise was bought by the soap manufacturer Eberhard Anheuser in 1860, and the following year Anheuser's daughter married Adolphus Busch (*q.v.*), a brewery supplier who became the driving force behind the brewery's future success. Busch pioneered the use of refrigerated railcars and of pasteurization in the brewing industry as part of his efforts to create the first nationally selling beer in the United States. In 1875 E. Anheuser & Company's name was changed to Anheuser-Busch Brewing Association, and in 1876 the company introduced a new, light-coloured beer called Budweiser. Busch became president of the company in 1879.

The company greatly expanded its brewing operations during the presidency (1946-75) of August Anheuser Busch, Jr., and the latter's son August A. Busch III headed the firm into the late 20th century. By then Anheuser-Busch Companies had become the world's largest brewer owing to its popular Budweiser and Michelob lines. The company is also a major owner of family-entertainment attractions. Among the latter are four Sea World amusement parks; Busch Gardens (The Dark Continent), a zoo and amusement park in Tampa, Fla., that has African themes; and Busch Gardens (The Old Country), an amusement park near Williamsburg, Va., that has historical European themes. Anheuser-Busch also owned the St. Louis Cardinals professional baseball team from 1953 to 1996.

anhinga (water bird): *see* snakebird.

Anhui, Wade-Giles romanization AN-HUI, Pinyin ANHUI, *sheng* (province), east-central China. Anhui is one of the smallest of China's provinces. It is landlocked and is bounded by the provinces of Kiangsu to the northeast, Chekiang to the southeast, Kiangsi to the south, and Hupeh and Honan to the west. The capital is Ho-fei.

A brief treatment of Anhwei follows. For full treatment, *see* MACROPAEDIA: China.

Anhui was the first part of southern China to be settled by the Chinese (Han) people. It was the hub of an early water-transportation system developed to carry grain. Anhwei was long regarded as the most backward province of eastern China, but since 1949 successful attempts have been made to utilize its economic and human resources.

The northern portion of Anhwei is occupied by the North China Plain—an immense level surface that has periodically been flooded by its dominant rivers. The southern section of the province, occupied mostly by a portion of the Yangtze River valley, is separated from the northern plain by a series of low mountains that stretch roughly from west to east. The northern plain is drained by the Huai River, which flows across the level plain and drains into the Hungtse Lake. The Huai River basin is subject to widespread and disastrous floods. Vast irrigation schemes constructed after 1949 on the major Huai tributaries have alleviated this flooding to a large extent and have also provided increased agricultural land and electric power. The Yangtze plain is crisscrossed by canals that are used for irrigation, drainage, and transport. Anhwei has a temperate monsoon climate characterized by hot, wet summers and cool, dry winters.

Anhui's regions of densest population are along the tributaries and banks of the Huai River above Pang-fou and in the diked areas along the right (south) bank of the Yangtze. There are four large towns in the province:

Ho-fei, Huai-nan, Pang-fou, and Wu-hu. The population is almost totally Han.

In the Huai River basin to the north, wheat is the predominant crop, while rice is grown in the Yangtze River basin to the south. Most of the land produces two crops a year. Summer crops include rice, sweet potatoes, kaoliang (sorghum), soybeans, peanuts (groundnuts), and sesame. Winter crops are wheat, corn (maize), barley, rape (an herb of the mustard family), peas, and green manure crops that are plowed under as fertilizer. The main industrial and commercial crops are vegetable oilseeds, cotton, tea, fibres, and tobacco. Anhwei has been famous for its tea since the 7th century.

Pigs are the main source of meat, and sheep are raised in increasing numbers in northern Anhwei. Coal, iron ore, and iron and steel are all produced in Anhwei. Secondary in importance are textiles and machine accessories. Area 54,000 square miles (139,900 square km). Pop. (1994 est.) 58,970,000.

anhydride, any chemical compound obtained, either in practice or in principle, by the elimination of water from another compound. Examples of inorganic anhydrides are sulfur trioxide, SO_3 , which is derived from sulfuric acid, and calcium oxide, CaO , derived from calcium hydroxide. Sulfur trioxide and other oxides formed by the removal of water from an acid are often called acid anhydrides, whereas those such as calcium oxide that are produced by a base upon the loss of water are designated basic anhydrides.

The most important of the organic anhydrides is acetic anhydride, $(\text{CH}_3\text{CO})_2\text{O}$. It is prepared industrially in either of two ways: by atmospheric oxidation of acetaldehyde in the presence of a metal acetate; and from acetic acid by reaction with acetylene or ketene. Other organic anhydrides can be prepared from carboxylic acids by reaction with acetic anhydride, ketene, methoxyacetylene, or isopropenyl acetate. Anhydrides also are produced when acyl halides react with acetic anhydride or with carboxylic acid and pyridine.

The organic anhydrides are used to introduce the acyl group (RCO) in organic synthesis. They react with water to give carboxylic acids, with alcohols or phenols to give esters, and with ammonia and amines to give amides. Acetic anhydride is employed in the manufacture of cellulose acetate, which is widely used as a base for magnetic tape and in the manufacture of textile fibres. Also, it is heated with salicylic acid to produce the medicinal chemical acetylsalicylic acid (aspirin).

anhydrite, an important rock-forming mineral, anhydrous calcium sulfate (CaSO_4). It differs chemically from gypsum (to which it alters in humid conditions) by having no water of crystallization. Anhydrite occurs most often with salt deposits in association with gypsum, as in the cap rock of the Texas-

Anhydrite from Lockport, N.Y.

By courtesy of the Field Museum of Natural History, Chicago, photograph, John H. Gerard

Louisiana salt domes. Anhydrite is one of the major minerals in evaporite deposits; it also is present in dolomites and limestones, and as a gangue mineral in ore veins. It is used in plasters and cement as a drying agent. Anhydrite crystals possess orthorhombic symmetry. For physical properties, *see* sulfate mineral (table).

Ani, ancient city site in extreme eastern Turkey. Ani lies east of Kars and along the Arpaçay (Akhuryan) River, which forms the border with Armenia to the east.

Situated along a major east-west caravan route, Ani first rose to prominence in the 5th century AD and had become a flourishing town by the time Ashot III the Merciful (reigned 952-977), the Bagratid king of Armenia, transferred his capital there from Kars in 961. Thus began a golden age for the city, which was beautified under two subsequent Bagratid rulers. The many churches built there during this period included some of the finest examples of medieval architecture. With a peak population of about 100,000 by the early 11th century, Ani was larger than any European city and rivaled Baghdad, Cairo, and Constantinople in its size and magnificence. It remained the chief city of Armenia until Mongol raids in the 13th century and a devastating earthquake in 1319 sent it into an irreparable decline. Eventually the site was abandoned. The handful of surviving churches and the remnants of the city walls attest to the extraordinary quality of Armenian stonework during the Middle Ages. The modern Turkish village of Ocaklı is nearby.

ani, any of three species of big-billed, glossy black birds of the genus *Crotophaga* of the cuckoo family (Cuculidae), of tropical America. These insect eaters forage on the ground in close and noisy flocks, often in fields with cattle. The bill is high-arched, bladelike, and

Ani (*Crotophaga*)

J. Foott—Bruce Coleman Inc.

hook-tipped; the tail is long and broad; the wings are short; and the plumage is floppy, so that the bird looks disheveled. Anis fly poorly and utter whining cries. They build a communal tree nest of twigs, in which several females may lay a total of 25 chalky-blue eggs (usually 10 to 15) and share duties of incubation and chick raising.

The common, or smooth-billed, ani (*C. ani*), found from southern Florida to Argentina, is a bird 36 cm (14 inches) long that looks like a huge-beaked grackle. The great ani (*C. major*) is common in swamplands of South America, chiefly east of the Andes. The groove-billed ani (*C. sulcirostris*), found from southern Texas to western Peru and northern Brazil, has several grooves in the upper mandible.

Aniakchak National Monument and Preserve, formerly ANIAKCHAK NATIONAL MONUMENT, national monument and preserve in southwestern Alaska, U.S., on the southern shore of the Alaska Peninsula. Proclaimed a national monument in 1978, the area underwent boundary and title changes in 1980. Aniakchak is a great dry caldera in the volcanically active Aleutian Mountains that last erupted in 1931. The crater, with an average

diameter of about 6 miles (10 km), includes lava fields and cinder cones. Surprise Lake, the outlet of which cascades through a 1,500-foot (450-metre) rift in the crater wall, forms the Aniakhak River. The monument and preserve cover an area of 942 square miles (2,440 square km).

Anicetus, SAINT (fl. 2nd century; b. Syria?—d. Rome; feast day April 17), pope from approximately 155 to approximately 166.

Possibly a Syrian, Anicetus laboured to combat the errors of the heresies of Valentin and Marcion and to prevent heresies, working particularly against the Marcionites and Gnostics. Although he suffered tribulations, it is questionable whether or not he was actually martyred. During his pontificate St. Polycarp, bishop of Smyrna, visited Rome (c. 154/155) to confer with him about the controversy over the date of Easter. He allowed Polycarp to celebrate the Eucharist in his church on the Eastern date.

aniconism, in religion, opposition to the use of icons or visual images to depict living creatures or religious figures. Such opposition is particularly relevant to the Jewish, Islāmic, and Byzantine artistic traditions.

The biblical Second Commandment (part of the First Commandment to Roman Catholics and Lutherans), "You shall not make yourself a graven image, or any likeness of anything," which had been intended as a protection against idol worship, came to have a restricting effect on the production of Jewish art, though this effect varied in strength in different periods and was strongest on sculpture. Figural representations were absolutely prohibited in the early period of Islām and under the Berber dynasties of Africa and the Mamlūks of Egypt and Syria, though under the 'Abbāsids and most of the Shī'ite and Turkish dynasties, it was excluded only from public buildings. In the Byzantine Empire, during the Iconoclastic Controversy (725–843), a ban was imposed on the representations of saintly or divine personages.

Anielewicz, Mordecai, also spelled MORDECHAI ANILOWITZ (b. 1919, Wyszaków, Poland—d. May 10, 1943, Warsaw), hero and principal leader of armed Jewish resistance in the Warsaw Ghetto during World War II.

Anielewicz was born into a working-class family and attended Hebrew gymnasium. As a boy he joined Betar, a Zionist youth organization that among other things advocated self-defense for Jews. By 1940 he had gone to Warsaw and become active in the branch there of a pro-Soviet group of young Zionists, Hashomer Hatzair. When Germany invaded Poland, he escaped to Wilno (now Vilnius), which the Soviet Union had annexed with Lithuania. He eventually made his way back to the Warsaw Ghetto, where he set up an underground newspaper, *Neged Hazerem* ("Against the Stream"), and developed cultural and educational activities. He was out of Warsaw, spreading his educational and political ideas underground in western Poland, when the population of the Warsaw Ghetto was decimated by deportation and execution in the late summer of 1942. Anielewicz had become convinced that Jews in Adolf Hitler's Europe should protect themselves with arms, and he rushed back to Warsaw to urge armed resistance on his elders, most of whom feared that resistance would fuel intolerable retaliation by the Nazis. With strong support from other young activists, notably Itzhak Zuckerman, his view prevailed, resulting in the formation of the Jewish Combat Organization (Żydowska Organizacja Bojowa; ŻOB). Anielewicz was the obvious choice to command the ŻOB. He stressed discipline, the

construction of bunkers, and the acquisition of arms in the ghetto.

On Jan. 18, 1943, the Germans entered the ghetto to select Jews for a new shipment to the death camp at Treblinka, and the ŻOB met them with force, mainly pistols and grenades, starting a fight in the streets that lasted four days and killed about 50 Germans—and all of the ŻOB defenders except Anielewicz himself. The Germans withdrew and for two months tried various deceptions to persuade the ghetto's remaining Jews to go peacefully to the boxcars. Anielewicz had effectively become the commander of the ghetto as well as the ŻOB, and he pushed defensive preparations until the Germans returned with 2,000 troops and tanks on April 19. The ŻOB held them off at first, then gave ground slowly until on May 8 the Germans found its headquarters bunker and gassed it. Civilian occupants surrendered, but Anielewicz and about a hundred comrades died, those not killed in the fighting taking their own and each other's lives to avoid falling alive into Nazi hands. He is commemorated in Israel by a kibbutz, Yad Mordecai. *See also* Warsaw Ghetto Uprising.

Aniene River, also called TEVERONE, Latin ANIO, major tributary of the Tiber (Tevere) River in central Italy. It rises from two springs in the Simbruini Mountains near Subiaco, southeast of Rome, flows through a narrow valley past Tivoli, and meanders through the Campagna di Roma (territory) to join the Tiber north of Rome. It is 67 miles (108 km) long and has a drainage basin of 569 square miles (1,474 square km). The Roman emperor

Ponte Nomentano on the Aniene River, Italy
Anderson—Allan from Art Resource

Nero created a group of artificial lakes in the upper course of the river above Subiaco and built a villa there, the remains of which survive. In Roman times, two huge aqueducts, the Anio Vetus and the Anio Novus, supplied Rome with water from the river. The series of falls at Tivoli, where the Aniene descends from the mountains to the plain, were once a main scenic attraction of the Roman countryside; but the heavy use of the river's waters by hydroelectric plants and by aqueducts has reduced the once-famous cascades to a trickle.

aniline, an organic base used to make dyes, drugs, explosives, plastics, and photographic and rubber chemicals.

Aniline was first obtained in 1826 by the destructive distillation of indigo. Its name is taken from the specific name of the indigo-yielding plant *Indigofera anil* (*Indigofera suffruticosa*); its chemical formula is $C_6H_5NH_2$.

Aniline is prepared commercially by the catalytic hydrogenation of nitrobenzene or by the action of ammonia on chlorobenzene. The reduction of nitrobenzene can also be carried out with iron borings in aqueous acid.

A primary aromatic amine, aniline is a weak base and forms salts with mineral acids. In acidic solution, nitrous acid converts aniline into a diazonium salt that is an intermediate in the preparation of a great number of dyes and other organic compounds of commercial

interest. When aniline is heated with organic acids, it gives amides, called anilides, such as acetanilide from aniline and acetic acid. Monomethylaniline and dimethylaniline can be prepared from aniline and methyl alcohol. Catalytic reduction of aniline yields cyclohexylamine. Various oxidizing agents convert aniline to quinone, azobenzene, nitrosobenzene, *p*-aminophenol, and the phenazine dye aniline black.

Pure aniline is a highly poisonous, oily, colourless substance with a pleasant odour.

aniline green (dye): *see* malachite green.

animal, any member of the kingdom Animalia, a group of multicellular organisms that are thought to have evolved independently from the unicellular eukaryotes. Animals differ from members of the two other multicellular kingdoms, the plants (Plantae) and the fungi (Mycota), in fundamental variations in morphology and physiology.

A brief treatment of animals follows. For full treatment, *see* MACROPAEDIA: Animals. Other aspects of the subject of animals are treated in the following MACROPAEDIA articles. For descriptions of various classes and orders of animals, *see* Sponges; Cnidarians; Aschelminths; Moss Animals; Lamp Shells; Mollusks; Annelids; Arthropods; Arachnids; Crustaceans; Insects; Echinoderms; Chordates; Fishes; Amphibians; Reptiles; Birds; Mammals; Evolution, Human. *See also* Cats; Dogs. For discussions of animals in relation to the biosphere, *see* Biosphere; Growth and Development, Biological. For special characteristics of animals, *see* Behaviour, Animal; Learning, Animal. For the study of animals, *see* Biological Sciences. For a description of the place of animals in the circle of learning and for a list of both MACROPAEDIA and MICROPAEDIA articles on the subject, *see* PROPAEDIA: Part Three.

At the cellular level, the most obvious distinction between animals and plants is that the animal cell wall is either absent or composed of a nitrogenous material, whereas the plant cell wall is composed of a carbohydrate material—cellulose. In general, animals are distinguished from plants and fungi by the capacity for spontaneous movement and rapid motor responses to stimuli. The mobility afforded by muscles in turn requires much more elaborate systems of sensory reception and internal communication and greater levels of general complexity than are found in plants or fungi. Animals account for about three-quarters of the living species on Earth; this diversity reflects the flexibility in feeding, defense, and reproduction that mobility gives them.

The animal and the plant both require food; but, although both animals and plants take their water and inorganic salts directly as such, the animal cell can absorb its carbohydrate and protein food only in the form of complex organic substances; it is dependent, in fact, on the preexistence of these organic substances, themselves the products of living matter, and in this respect the animal is essentially a parasite on existing animal and plant life.

In general, an animal is a living organism that is incapable of synthesizing carbohydrates and proteins from inorganic or simple organic substances but must ingest them in complex form as food.

animal behaviour, any observable activity of a whole living animal. The ways in which animals solve their common problems—*e.g.*, eating, drinking, protecting themselves from predators, reproducing, and grooming—are all the concerns of an ethologist, a scientist who studies animal behaviour.

A brief treatment of animal behaviour follows. For full treatment, *see* MACROPAEDIA: Behaviour, Animal.

Animal behaviour is largely dictated by innate programming. Depending on external factors

such as the season or the cycle of the Moon, an animal's body may secrete hormones that regulate its metabolism or behaviour. Hormones, for example, will decrease a bear's metabolic rate until the animal falls into a torpid state that lasts throughout the winter, and other hormones encourage the bear throughout its active months to consume enough food so that it will survive hibernation. None of this is under the bear's conscious control—no more than a woman can control her menstrual cycle.

Animals solve their problems in a variety of ways. In the winter, birds remedy their reduced food supply by migrating toward the Equator or Southern Hemisphere where the seasons are reversed. It is not fully known whether birds navigate over long distances by the stars and Sun or by a compass sense. Nor can the behaviour of salmon, which find their way back to the same freshwater where they were born after years in the ocean, be explained. Some hormones are produced at particular times; e.g., sex hormones, which prepare the body for parenthood. Other hormones may be triggered by a particular occurrence, such as the sight of a predator.

Many animals also secrete chemical substances called pheromones, which send messages to other animals. When a female fly is ready to produce eggs, she releases a pheromone into the air. A male that smells this substance will immediately approach and inseminate the female or any object that a scientist may have dabbed with the pheromone. Pheromones can also serve as a message between males, as when a dog marks with urine what it would like to claim as its territory. Still other pheromones transmit information to the entire group, as in an ant trail that leads to a food source.

Animals that live in communities demonstrate a variety of social behaviour. Some perform actions that benefit others without receiving any direct benefit themselves. Animal altruism helps to preserve a species, as when parents gather food for their young and protect them against predators. Similarly, rats and monkeys in laboratory experiments will sacrifice food rather than allow others of their species to receive an electrical shock.

Complex animal societies tend to build shelters (e.g., an ant hill), while others establish and guard territories. A pattern of leaders and followers within an animal society indicates some social organization, as in herds of sheep or schools of fish, but does not always indicate that the group has a leader. Among many species of birds, for example, different members lead the flock during a single flight.

A dominance hierarchy, in which one animal bullies another into submitting to its wishes, is present in almost all animal interactions and does not indicate social organization. Ethologists argue that the more advanced animal societies do not have dominance hierarchies. Other factors of social behaviour in animals include migration patterns and labour division.

Social behaviour should not be correlated with intelligence or with evolutionary development. The simplest organisms form colonies, and the most complex colonies are formed by the relatively simple ant and bee. Man, the highest animal on the evolutionary scale, can be relatively solitary. Social behaviour is not a key to evolutionary development but rather is the adaptation of animals to the world around them.

animal breeding, the controlled propagation of domestic animals with the purpose of improving inherent qualities considered desirable by man. Animals are bred for utility (e.g., food, fur), sport, pleasure, and research.

A brief treatment of animal breeding follows. For full treatment, see MACROPAEDIA: Farming and Agricultural Technology.

Improvement or favourable change in an-

imals is brought about by changing the inheritance or the environment. Hereditary characteristics are those that arise from gene differences and account for common differences in animals as, for example, the white-face characteristic of Hereford cattle. Nonhereditary differences are mainly environmental; e.g., animals poorly fed and managed will not develop to their maximum capacity. Environment, if markedly improved, can bring forth changes in animals with dramatic swiftness, but the changes continue only while the improved environment prevails. Changes in the hereditary makeup of a population are made slowly, but usually are fairly permanent. Some characteristics, however, revert to the original level when man withdraws his selectivity.

Origin of breeds. Breeds were formed usually from small localized groups thought to be superior to the prevailing stock. Man began to isolate such groups to get a more desirable stock. Certain hereditary traits became characteristic of animals within an area, which tended to distinguish them from others of the same species. The English began to develop the purebred idea for breeding stock late in the 18th century. As breeds were formed and recognized, herdbooks were started to maintain pedigree records of selected animals.

The animal breeder had in mind a type or ideal animal, representing particular desirable characteristics, these being determined by the purpose for which the animal was intended. Thus the two common types of sheep are mutton and wool, and the two main types of cattle are dairy and beef; analogous designations exist for other kinds of livestock. The breeder of pet or fancy stock had mainly the human appeal to consider.

An effective breeding program must include measurements of the individual for comparison with the ideal. The measuring of milk production in terms of quantity and butterfat content was one of the first attempts at production evaluation. However, since production typically varies from year to year, and certain other features do not lend themselves to objective measurement, overall merit is generally not based on a few characteristics, but on several and on their interaction.

Systems of selection and mating. With an ideal and methods of evaluation established, the next step in animal breeding is to choose the breeding stock. Several types of selection are commonly distinguished. Mass selection is the choosing of animals for producing the next generation wholly upon their own individual merit; it is sometimes referred to as phenotypic selection, as it is based on what an animal is and does. Pedigree selection is based upon the merit of the individual's ancestors. Family selection refers to selection based mainly upon collateral, or nonlineal, relatives or those descended from the same stock but from a different line. Progeny testing is a means of estimating an animal's breeding worth and is based on the performance of offspring or lineal or direct descendants.

After the breeding stock has been chosen, the next step is to decide how they should be mated. Systems of mating range from the mating of closely related individuals, or inbreeding, to line breeding, which combines mild inbreeding with selection, to the mating of unrelated individuals, as in crossbreeding. Mating systems may also be assortative, that is, based upon similarity of characteristics. In outbreeding, it is not uncommon for the progeny to surpass the parent stock in vigour and vitality. The main use of cross breeding has been in commercial livestock production, in which the method results in faster and more economical gains. The mule is an outstanding example of a hybrid resulting from a cross between species or an extremely wide outcross; in some such crosses fertility is impaired.

The development of artificial insemination techniques has permitted the extensive use of

selected males, since more females can be bred to one male by this method than by natural service. The practice has proved extremely successful with horses and with dairy cattle. Increased understanding of the principles of population genetics has greatly enhanced the efficacy of modern breeding programs. See also cat; dog; horse.

animal communication, the transmission of information from one animal to another by means of sound, visible sign or behaviour, taste or odour, electrical impulse, touch, or a combination of these mediums. The existence, nature, and extent of animal communication have long been subjects of speculation by man and have in modern times stimulated much scientific investigation.

A brief treatment of animal communication follows. For full treatment, see MACROPAEDIA: Behaviour, Animal.

Most animal communication employs sound, which has several advantages over other mediums. It fades quickly, leaving no trace of the communicator's location, and it can vary in pitch, duration, volume, and repetition, thus permitting the development of special codes. Sound may also be used in many settings, conditions, and situations in which other means are less feasible, such as in dense forests, across great distances, in darkness, or under water. Most communication is vocal, but there are many exceptions. Male gorillas beat their chests, the ground, or any suitable object, while beavers slap the surface of the water with their tails, sending signals through the underwater tunnels leading to their lodges. Hyenas, which hunt in packs of up to 30, have a rich repertoire of grunts, snorts, and giggles. Their complex tracking strategy is guided by their sounds, and once the prey is taken, other sounds, including their well-known laugh, calls the rest of the pack to join in the feast. In contrast, a small bird squawking at the sight of a falcon serves to warn other birds that appropriate actions must be taken to avoid imminent danger.

Visual communication may be conducted through the use of badges (i.e., special characteristics such as a patch of bright colour or horns), which give some indication of the communicator's identity (e.g., species, sex, and age). A juvenile baboon, for example, can be distinguished by hair colour, which permits it to act in an immature manner forbidden to adults. Information can also be conveyed visually by the assumption of various poses or motions. Males of many species adopt characteristic attitudes to attract females for mating, and females have evolved various ways of indicating readiness for copulation. Some species set aside a display arena or build a structure that is itself intended as a form of communication, such as the elaborate bower built by the bowerbird. Other visible signs include special dung heaps left by rabbits and the scars left on tree trunks by bears.

The use of chemical signals, called pheromones, which are produced by the animal's endocrine system, is yet another form of communication. Ants exude an unpleasant aroma designed to convince a predator of their bad taste. Some pheromones are deposited with urine or feces to mark territorial boundaries, as demonstrated by the familiar habit of dogs. Other chemical signs may be produced by a female in heat to signify sexual readiness or laid down as a trail along the ground, signalling the direction of a food source. There are even pheromones that dictate the hierarchy within a group, but these are the least understood.

Touch is less prevalent as a mode of communication than sound, sight, or smell. The dance of the honeybee, which is performed in

a dark hive, conveys primarily through touch the direction and distance to a food source; this activity also includes an element of taste, because the honeybee usually has some of the nectar on its body. Some male spiders cautiously announce their presence by strumming on a female's web, indicating that they are to be taken as mate and not prey.

Eels and many other fishes that live in muddy waters use electrical impulses to send messages to each other and to ward off enemies.

animal interlace, in calligraphy, rich, fanciful decorative motif characteristic of work by the Hiberno-Saxon book artists of the early Middle Ages in the British Isles. Its intertwined, fantastic animal and bird forms are often densely and minutely detailed—an ex-

Interlace patterns of the initial page of the Gospel According to St. John from the Lindisfarne Gospels, Hiberno-Saxon, 8th century (British Library, Cotton Nero D. IV, fol. 211)

By courtesy of the trustees of the British Library

ample in the Book of Kells (c. 800) contains 158 interlacements in a space of 0.25 square inch (1.61 square cm). Another work of comparable stylistic maturity is the Lindisfarne Gospels, written in Northumbria in honour of St. Cuthbert soon after his death in 687.

animal worship, veneration of an animal, usually because of its connection with a particular deity. The term was used by Western religionists in a pejorative manner and by ancient Greek and Roman polemicists against theriomorphic religions—those religions whose gods are represented in animal form. Most examples given for animal worship in primitive religions, however, are not instances of worship of an animal itself. Instead, the sacred power of a deity was believed to be manifested in an appropriate animal that was regarded as an epiphany or incarnation of the deity (e.g., fertility deities frequently were represented as manifesting themselves in the form of a bull).

The universal practice among hunting peoples of respect for and ceremonial behaviour toward animals stems from the religious customs attendant on the hunt and not from worship of the animal itself. Another phenomenon that has been confused with animal worship is totemism, in which animal or plant categories fulfill a social classificatory system that does not imply worship of the animal.

Animal symbolism in religious iconography and allegory has been used in associating certain qualities with certain animal species (e.g., wisdom with the owl—hence, Athena, the Greek goddess of wisdom, is frequently

represented as an owl). This associative factor does not imply, as polemicists have strongly suggested, a more primitive style in which an animal itself was worshiped and then later rationalized into an anthropomorphic figure or abstract quality. In contemporary scholarship, the term animal worship seldom occurs, because it has been rejected as a misleading interpretive category.

animal rights, rights said to belong to some of the higher nonhuman animals—or, on some views, to all nonhuman animals—by virtue of their cognitive abilities or their capacity to feel pleasure and pain or on other grounds.

The modern animal-rights movement developed in the 20th century as an outgrowth of the movement against cruelty to animals, which itself was rooted in antiquity. The Greek philosopher Pythagoras urged respect for the interests of animals, in part because he believed in the transmigration of souls between human and animal bodies. In contrast, Aristotle, the Neoplatonists, and the Stoics held that the infinite number of beings in the universe are arranged in a hierarchy (the "Great Chain of Being"), with humans (i.e., men), by virtue of their rationality, occupying the topmost level of corporeal beings. Animals, because of their presumed irrationality, were far below humans in the hierarchy, had no interests of their own, and indeed existed only for human benefit. These ideas were adopted by some early Christian philosophers and eventually found expression in medieval common law.

If St. Francis of Assisi was by reputation the greatest friend of animals, the French philosopher René Descartes was perhaps their greatest enemy. He and his followers believed that animals had no souls and therefore did not think or feel, and they treated them accordingly on the vivisection table. Late in the 18th century, the English utilitarian philosopher Jeremy Bentham argued against the traditional conception of animals as tools for human use by pointing out that animal pain and suffering was no less real than that felt by humans. "The question," he wrote, "is not, *Can they reason?* nor, *Can they talk?* but, *Can they suffer?*"

Perhaps the world's first anticruelty law was included in the legal code of the Massachusetts Bay Colony (U.S.) in 1641. In 1822 the British Parliament adopted the Martin Act, which forbade the "cruel and improper Treatment" of large domestic animals. Importantly, this and similar legislation subsequently passed elsewhere in Europe and the United States did not grant legal rights to animals nor change their status in the law as things for human ownership and use. The world's first animal welfare society—the Society for the Prevention of Cruelty to Animals—was founded in Britain in 1824, and similar organizations were soon created in other European countries. The first anticruelty society in the United States—the American Society for the Prevention of Cruelty to Animals—was chartered in the state of New York in 1866.

By the late 20th century, animal welfare societies and laws against cruelty to animals existed in almost every country in the world. Specialized animal advocacy groups also proliferated, including those dedicated to the preservation of endangered species and those that protested against painful or brutal methods of hunting animals, the mistreatment of animals raised for human food in "factory farms," and the use of animals in medical research and product testing and in entertainment.

The modern animal-rights movement is perhaps the first social reform movement to have been founded by moral philosophers. Its basic contention is that at least some nonhuman animals possess rights and interests that humans are morally obliged to respect. In the early 21st

century the two most prominent academic defenders of animal rights were the Australian philosopher Peter Singer and the American philosopher Tom Regan. Singer argued that many of the traditional ways in which humans use animals are unjustified, because their benefits to humans are negligible in comparison to the amount of animal suffering they entail or because the same benefits can be obtained in ways that do not involve the exploitation of animals. Regan held that, because the basic moral rights of humans are grounded in their possession of certain cognitive abilities, and because these abilities are also possessed by at least some of the higher nonhuman animals, such animals have the same basic moral rights as humans.

In response to challenges from philosophers such as Singer and Regan, opponents of animal rights have attempted to identify "morally relevant" differences between humans and animals that would justify the attribution of rights and interests to the former but not to the latter. Various such distinguishing features of humans have been proposed, including: the possession of a soul, the ability to use language, self-consciousness, a high level of intelligence, and the ability to recognize the rights and interests of others. With the exception of the first (which cannot be proved philosophically), such criteria face the difficulty that they do not seem to apply to all and only humans: each applies either to some humans but not to all, or to all humans but also to some animals.

In the late 20th century the animal-rights movement was joined by other academic and professional groups, including physicians, theologians, psychologists, and veterinarians. Beginning in the 1980s, lawyers and legal scholars constructed strategies designed to protect the interests of animals in court using the common law and existing statutes and constitutional provisions. Other scholars devised legal theories by which at least some animals would be entitled to basic legal rights, often for the same reasons as humans and on the basis of the same legal principles and values. *See also* vegetarianism.

animals, master of the, supernatural figure regarded as the protector of game in the traditions of early hunting peoples. The name was actually devised by Western scholars. In some traditions, the master of the animals is believed to be the ruler of the forest and guardian of all animals; in others, he is the ruler of only one species, usually a large animal of economic or social importance to the tribe. Thus, among Eurasian peoples the animal most frequently is the bear; among the reindeer cultures of the tundra, the reindeer; among the northern coastal peoples of Eurasia and America, the whale, the seal, or the walrus; among the North American Indians, the bear, the beaver, or the caribou; and among Mesoamerican and South American Indians, the wild pig, jaguar, deer, or tapir. In some traditions he is pictured in human form, at times having animal attributes or riding an animal; in others he is a giant animal or can assume animal form at will.

A complex system of customs governs the relationship between the master of the animals, the game animal, and the hunter. The master controls the game animals or their spirits (in many myths, by penning them). He releases a certain number to man as food. Only the allotted number may be killed, and the slain animal must be treated with respect. The master of the animals, if properly invoked, will also guide the hunter to the kill. The souls of the animals, when slain, return to the master's pens and give him a report of their treatment. If this system is violated, the master will avenge an animal improperly slain, usually by withholding game. A ceremony then must be held to remove the offense or a shaman sent to placate the master.

animation, the art of making inanimate objects appear to move. Animation is an artistic impulse that long predates the movies. In many respects, history's first recorded animator is Pygmalion of Greek and Roman mythology, a sculptor who created a figure of a woman so perfect that he fell in love with her and begged Venus to bring her to life. Some of the same sense of magic, mystery, and transgression still adheres to contemporary film animation, which has made it a primary vehicle for exploring the overwhelming, often bewildering emotions of childhood—feelings once dealt with by folktales.

The theory of the animated cartoon preceded the invention of the cinema by half a century. Early experimenters, working to create conversation pieces for Victorian parlours or new sensations for the touring Magic Lantern shows that were a popular form of entertainment, discovered the principal of persistence of vision: if drawings of the stages of an action were shown in the fast succession, the human eye would perceive them as a continuous movement. One of the first commercially successful devices, invented by the Belgian Joseph Plateau in 1832, was the phenakistoscope, a spinning cardboard disc that created the illusion of movement when viewed in a mirror. In 1834 Englishman William George Horner invented the zoetrope, a rotating drum lined by a band of pictures that could be changed. The Frenchman Émile Reynaud in 1876 adapted the principle into a form that could be projected before a theatrical audience. Reynaud became not only animation's first entrepreneur but, with his gorgeous, hand-drawn ribbons of celluloid conveyed by a system of mirrors to a theatre screen, he was the first artist to give personality and warmth to his animated characters.

With the invention of sprocket-driven film stock, animation was poised for a great leap forward. Though "firsts" of any kind are never easy to establish, the first film-based animator was probably American J. Stuart Blackton, whose *Humorous Phases of Funny Faces* (1906) launched a successful series of animated films for New York's pioneering Vitagraph Company. Later that year, Blackton also experimented with the stop-motion technique—in which objects are photographed, then repositioned and photographed again—for his short film *Haunted Hotel*.

In France, Émile Cohl developed a form of animation similar to Blackton's, though Cohl used relatively crude stick-figures rather than Blackton's ambitious newspaper-style cartoons. Coinciding with the rise in popularity of the Sunday comic sections of the new tabloid newspapers, the nascent animation industry recruited the talents of many of the best-known comic strip artists of the time, including Rube Goldberg, Bud Fisher (creator of *Mutt and Jeff*) and George Herriman (creator of *Krazy Kat*), but most soon tired of the fatiguing animation process and left the actual production work to others.

The one great exception among these early illustrators-turned-animators was Winsor McCay, whose elegant, surreal *Little Nemo in Slumberland* and *Dream of the Rarebit Fiend* remain pinnacles of comic-strip art. McCay created a hand-coloured short film of "Little Nemo" for use during his vaudeville act in 1911, but it was the film *Gertie the Dinosaur*, created for McCay's 1914 tour, that transformed the art. McCay's superb draftsmanship, fluid sense of movement, and great feeling for character gave viewers an animated creature who seemed to have a personality, a presence, and a life of her own. The first cartoon star had been born.

McCay made several other extraordinary films, including a recreation of *The Sinking of the Lusitania* (1918), but it was left to Pat Sullivan to extend McCay's discoveries. An Australian-born cartoonist who opened a studio in

New York City, Sullivan recognized the great talent of a young animator named Otto Messmer, one of whose casually invented characters—a wily black cat named Felix—was made into the star of a series of immensely popular one-reelers. Designed by Messmer for maximum flexibility and facial expressiveness, the round-headed, big-eyed Felix quickly became the standard model for cartoon characters: a rubber ball on legs who required a minimum of effort to draw and could be kept in constant motion.

This lesson did not go unremarked by the young Walt Disney, then working at his Laugh-O-gram Films studio in Kansas City, Mo. His first major character, Oswald the Lucky Rabbit, was a straightforward appropriation of Felix; when he lost the rights to the character in a dispute with his distributor, Disney simply modified Oswald's ears and produced Mickey Mouse.

Far more revolutionary was Disney's decision to create a cartoon with the new novelty of synchronized sound. *Steamboat Willie* (1928), Mickey's third film, took the country by storm. A missing element—sound—had been added to animation, making the illusion of life that much more complete, that much more magical. Later, Disney would add carefully synchronized music (*The Skeleton Dance*; 1929), three-strip Technicolor (*Flowers and Trees*; 1932), and the illusion of depth, with his multi-plane camera (*The Old Mill*; 1937). With every step, Disney seemed to come closer to a perfect naturalism, a painterly realism that suggested academic paintings of the 19th century.

For Disney, the final step was, of course, *Snow White and the Seven Dwarfs* (1937). Although not the first animated feature, it was the first to use up-to-the-minute techniques and the first to receive a wide, Hollywood-style release. Instead of amusing his audience with talking mice and singing cows, Disney was determined to give them as profound a dramatic experience as the medium would allow; he reached into his troubled childhood and reinvented this rich fable into a story of parental abandonment, sibling rivalry, and the onrush of adult passion.

With his increasing insistence for photographic realism in such films as *Pinocchio* (1940), *Fantasia* (1940), *Dumbo* (1941), and *Bambi* (1942), Disney perversely seemed to be trying to put himself out of business by imitating life too well. That was not the temptation followed by Disney's chief rivals in the 1930s, all of whom came to specialize in their own kind of stylized mayhem.

Max and Dave Fleischer had become successful New York animators while Disney was still living in Kansas City. The Fleischers invented the rotoscoping process, still in use today, in which a strip of live-action footage can be traced and redrawn as a cartoon. The Fleischers exploited this technique in their pioneering series *Out of the Inkwell* (1919–29). It was this series, with its lively interaction between human and drawn figures, that Disney struggled to imitate with his early Alice cartoons.

But if Disney was Mother Goose and Norman Rockwell, the Fleischers (Max produced, Dave directed) were stride piano and red whiskey. Their extremely urban, overcrowded, sexually suggestive and frequently nightmarish work—featuring the curvaceous torch singer Betty Boop and her two oddly infantile colleagues, Bimbo the Dog and Koko the Clown—charts a twisty route through the American subconscious and the 1920s and '30s, before collapsing into Disneyesque cuteness with the features *Gulliver's Travels* (1939) and *Mr. Bug Goes to Town* (1941); also released as *Hoppity Goes to Town*). The studio's mainstay remained the relatively impersonal *Popeye* series, based on the comic strip created by Elzie Segar. The spinach-loving sailor

was introduced as a supporting player in the Betty Boop cartoon *Popeye the Sailor* (1933) and quickly ascended to stardom, surviving through 105 episodes until *Baby Wants a Botleship* (1942), when the Fleischer studio collapsed and rights to the character passed to Famous Studios.

Less edgy than the Fleischers but every bit as anarchic were the animations produced by the Warner Bros. cartoon studio, known to its residents as "Termite Terrace." The studio was founded by three Disney veterans, Rudolph Ising, Hugh Harmon, and Friz Freleng, but it didn't discover its identity until Tex Avery, fleeing the Walter Lantz studio at Universal, joined the team as a director. Avery was young and irreverent, and he quickly recognized the talent of such staff artists as Chuck Jones, Bob Clampett, and Bob Cannon. Together they brought a new kind of speed and snappiness to the Warners product beginning with *Gold Diggers of '49* (1936). With the addition of director Frank Tashlin, musical director Carl W. Stalling, and voice interpreter Mel Blanc, the team was in place to create a new kind of cartoon character: cynical, wisecracking, often violent, who, refined through a series of cartoons, finally emerged as Bugs Bunny in Tex Avery's *A Wild Hare* (1940). Other characters, some invented and some reinterpreted, soon appeared in Warners' ranks: Daffy Duck, Porky Pig, Tweety and Sylvester, Pepe LePew, Foghorn Leghorn, the Roadrunner, and Wile E. Coyote. Avery left Warners and in 1942 joined Metro-Goldwyn-Mayer's moribund animation unit, where, if anything, his work became even wilder in films such as *Red Hot Riding Hood* (1943) and *Bad Luck Blackie* (1949).

In Europe, animation had meanwhile taken a strikingly different direction. Eschewing animated line drawings, filmmakers experimented with widely different techniques: in Russia and later in France, Wladyslaw Starewicz (also billed as Ladislav Starewicz), a Polish art student and amateur entomologist, created stop-motion animation with bugs and dolls; Alexandre Alexeïeff, a Russian working in France, developed the pinscreen technique that gave the effect of an animated steel engraving; Germany's Lotte Reiniger worked with silhouette animation and produced what may have been the first animated feature, *The Adventures of Prince Achmed* (1926); and abstract artists such as Oskar Fischinger, Hans Richter, and Viking Eggeling created "animated paintings," swirling compositions in colour and time.

Eastern Europe became the center of puppet animation, thanks largely to the engaging, folkloric work of Jiří Trnka (*Prince Bayaya*; 1950). Trnka's followers in Czechoslovakia and elsewhere took the puppet technique down far darker streets to the Kafkaesque byways of Jan Švankmajer (*Alice*, 1988) and the British-born Brothers Quay (*Street of Crocodiles*, 1986). Darker styles also developed in Poland in the work of Walerian Borowczyk and Jan Lenica, and in Yugoslavia, where the Zagreb school of animation became internationally famous with such films as Vatroslav Mimica's *Strasillo* (1957; *The Scarecrow*).

More traditional forms of line animation continued to be practiced in France by Paul Grimault (*The King and the Mockingbird*; begun in 1948, completed 1979), in Italy by Bruno Bozzetto (*Allegro Non Troppo*, 1976), and in Britain by John Halas and Joy Batchelor (*Animal Farm*, 1955), Bob Godfrey (*Kama Sutra Rides Again*, 1972), and Richard Williams (*Raggedy Ann and Andy*, 1977). In Canada, Norman McLaren of the National Film Board proved a restless and brilliant researcher, spinning delightful films from techniques such as painting directly on film

(*Blinkity Blank*, 1955), and the "pixellation" of living actors (*Neighbours*, 1952).

A victim of rising production costs, full-figure, feature-length animation appeared to be dying off until two developments gave it an unexpected boost in the 1980s. The first was the Disney company's discovery that the moribund movie musical could be revived and made palatable to contemporary audiences by adapting it to cartoon form (e.g. *The Little Mermaid*, 1989); the second was the discovery of computer animation technology, which greatly reduced expenses while providing new forms of expression. Although most animated films now use computer techniques to a greater or lesser degree, the finest, purest achievements in the genre are the work of John Lasseter, whose Pixar studios has evolved from experimental shorts like *Luxor, Jr.* (1986) to the lush feature *A Bug's Life* (1998).

As animation's first century draws to a close, the most exciting developments are found on two widely distant fronts: the *anime* of Japan and the prime-time TV cartoons of the United States. An offspring of the dense, novelistic style of Japanese comic books and the cut-rate techniques developed for television production in 1960, *anime* such as Miyazaki Hayao's *Princess Mononoke* (1998) are the modern equivalent of the epic folk adventures once filmed by Mizoguchi Kenji (*The 47 Ronin*, 1941) and Kurosawa Akira (*Yojimbo*, 1961; "The Bodyguard"). Kon Satoshi's *Perfect Blue* (1998) suggests the early Japanese New Wave of Oshima Nagisa with its violent exploration of a media-damaged personality.

Television animation in the United States, pioneered in the 1950s by Joseph Hanna and William Barbera (*Yogi Bear*, *The Flintstones*), was for years synonymous with primitive techniques and careless writing. But with the debut of Matt Groening's *The Simpsons* in 1989, TV animation became home to a kind of mordant social commentary, or outright absurdism (John Kricfalusi's *Ren and Stimpy*), that was too pointedly aggressive for live-action realism. When Mike Judge's *Beavis and Butt-Head* debuted on MTV in 1993, the rock-music cable channel discovered that cartoons could push limits of censorship in ways no live-action television productions could. Following Judge's success in 1997 was Trey Parker and Matt Stone's *South Park*, a series centred on foulmouthed kids growing up in Colorado, rendered in a flat, cut-out animation style that would have looked primitive in 1906. The spiritual father of the new television animation is Jay Ward, whose *Rocky and His Friends*, first broadcast in 1959, turned the threadbare television style into a vehicle for absurdist humour and adult satire.

Despite these boundary-pushing advances, full-figure, traditionally animated films continue to be produced, most notably by Don Bluth (*An American Tale*, 1986), a Disney dissident who moved his operation to Ireland, and Brad Bird, a veteran of *Simpsons* minimalism who has moved on to the spectacular full technique of *The Iron Giant* (1999). As digital imaging techniques continue to improve in quality and affordability, it becomes increasingly difficult to draw a clear line between live action and animation. Films such as *The Matrix* (1999), *Star Wars: Episode One* (1999), and *Gladiator* (2000), incorporate backgrounds, action sequences, and even major characters conceived by illustrators and brought to life by technology. Such techniques are no less creations of the animator's art than were Gertie, Betty Boop, and Bugs Bunny. (Da.Ke.)

animism, belief in spiritual beings who are concerned with human affairs and capable of

intervening in them—a belief pervasive among most indigenous peoples. Animistic beliefs were first competently surveyed by Sir Edward Burnett Tylor in the late 19th century.

The term animism, as it survives in contemporary anthropological usage, denotes not a single creed or doctrine but rather a view of the world consistent with a certain range of religious beliefs and practices, many of which may survive in more complex and hierarchical religions.

For full treatment, see MACROPAEDIA: Religious and Spiritual Belief, Systems of.

anion, atom or group of atoms carrying a negative electric charge. See ion.

anise (*Pimpinella anisum*), annual herb of the parsley family (Apiaceae, or Umbelliferae), cultivated chiefly for its fruits, called aniseed, the flavour of which resembles that of licorice. The plant, up to 0.75 m (2.5 feet) tall, has long-stalked basal leaves and shorter, stalked stem leaves. Its small, yellowish white flowers form loose umbels. The fruit, or seed, is nearly ovoid in shape, about 3.5 mm (0.12 inch) long, and has five longitudinal dorsal ridges. Native to Egypt and the eastern Mediterranean region, anise is cultivated in southern Europe, southern Russia, the Middle East, North Africa, Pakistan, China, Chile, Mexico, and the United States.

Aniseed is widely used to flavour pastries; it is the characteristic ingredient of a German bread called *Anisbrot*. In the Mediterranean region and in Asia, aniseed is commonly used in meat and vegetable dishes. It makes a soothing herbal tea and has been used medicinally from prehistoric times. The essential oil content is about 2.5 percent, and its principal component is anethole. The essential oil is used to flavour absinthe, anisette, and Pernod liqueurs.

Anise (*Pimpinella anisum*)

A-Z Botanical Collection

Star anise is the dried fruit of the *Illicium verum*, an evergreen tree of the Magnoliaceae family, indigenous to the southeastern part of China and to Vietnam. Its flavour and uses are similar to those of anise. The fruit takes its name from the starlike arrangement of its carpels around a central axis. The dried fruit is about 0.25 to 0.5 cm (0.1 to 0.2 inch) in diameter; individual carpels are usually about 1 cm in length and contain a single seed. Dried carpels are hard, rough, and reddish brown; the seeds are smooth, lustrous, and light brown in colour. The dried fruit's essential-oil content is about 3 percent, and its principal component is anethole.

Anisian Stage, the lower of two subdivisions in the Middle Triassic Series, representing all those rocks deposited worldwide during the Anisian Age (240 to 235 million years ago). The stage's name is derived from an area along the Anisus River at Grossreifling in the Aus-

trian Alps, where a thick sequence of rocks was deposited in a marine environment. The limestone strata there contain four ammonite biozones (shorter spans of time characterized by a particular type of fossil mollusk), beginning with *Lenotropites caurus* and ending with *Frechites chuscha*. No global stratotype section and point (GSSP) for the base of the Anisian Stage has been approved by the International Commission on Stratigraphy. Rocks of the Anisian Stage underlie those of the Ladinian Stage and overlie rocks of the Spathian Stage.

anisotropy, in physics, the quality of exhibiting properties with different values when measured along axes in different directions. Anisotropy is most easily observed in single crystals of solid elements or compounds, in which atoms, ions, or molecules are arranged in regular lattices. In contrast, the random distribution of particles in liquids, and especially in gases, causes them rarely, if ever, to be anisotropic.

A familiar example of anisotropy is the difference in the refractive index of light along different axes of crystals of the mineral calcite. Another example is the electrical resistivity of selenium, which is high in one direction but low in the other; when an alternating current is applied to this material, it is transmitted in only one direction (rectified), thus becoming a direct current.

anitya (Buddhism): see anicca.

Anius, in Greek mythology, the son of the god Apollo and of Rhoeo, who was herself a descendant of the god Dionysus. Rhoeo, when pregnant, had been placed in a chest and cast into the sea by her father; floating to the island of Delos, she gave birth to Anius, who became a seer and a priest of Apollo. Anius' three daughters, Oeno, Spermio, and Elais—that is, Wine, Grain Seed, and Oil—were granted by Dionysus the gift of bringing these three crops to fruition. They supplied both the Greek expedition on its way to Troy and Aeneas in his flight from Troy to Italy.

Anjala League (1788–89), a conspiracy of Swedish and Finnish army officers that undermined the Swedish war effort in the Russo-Swedish War of 1788–90. Shortly after the outbreak of war, 113 officers in the Finnish town of Anjala dispatched a letter to Empress Catherine II the Great of Russia calling for peace on the basis of the pre-1743 status quo—one favourable to Sweden. Although this condition made Catherine's acceptance unlikely, it did not lessen the letter's treasonable nature. When King Gustav III of Sweden learned of the letter, he called upon the officers to repudiate it in return for a full pardon. The officers, however, answered that the war was unjust and therefore Swedes could not be inspired to fight to victory; they denied that their act had been treasonable, noting that they would consider a refusal by Catherine to negotiate as a personal attack on them. Unmoved by this explanation, Gustav III, after first dealing successfully with an attack in the west by Denmark, punished the Anjala group in 1789: one officer was executed, and many were imprisoned.

first

Anjō, city, Aichi ken (prefecture), Honshu, Japan, in the middle of the Hekikai Terrace. Irrigation was introduced into the area in the late 19th century, permitting cultivation of two crops of rice and wheat annually. In 1891 the Anjō station on the railroad between Tokyo and Kōbe was opened, and the new town developed around it. With far-sighted planning and the early establishment of agri-

cultural cooperatives, Anjō became a model farm community. Its diversified farming of rice, wheat, poultry, and cattle lent it the name Little Denmark of Japan. After 1960 industrialization increased rapidly, and farming became secondary to a large textile factory and several smaller plants making machinery and metal products. Pop. (1995) 149,464.

Anjou, historical and cultural region encompassing the western French *département* of Maine-et-Loire and coextensive with the former province of Anjou. The former province of Anjou also encompassed the regions of La Flèche and Château-Gontier.

The *gouvernement* of Anjou in 1789

Organized in the Gallo-Roman period as the *Civitas Andegavensis*, it later became the countship of Anjou and (from 1360) the duchy of Anjou. Under the Carolingians, Anjou was nominally administered by a count representing the French king, but the region became vulnerable to attack by marauding Vikings, or Northmen, in the 9th century.

Anjou, **DUKES OF**, titled French nobility, comprising royal princes of the blood, grouped below chronologically and indicated by the symbol •.

• **Anjou, (Hercule-) François, Duke (duc) d'**, also called (1566–76) **DUKE D'ALENÇON** (b. March 18, 1554, Saint-Germain-en-Laye, Fr.—d. June 10, 1584, Château-Thierry), fourth and youngest son of Henry II of France and Catherine de Médicis; his three brothers—Francis II, Charles IX, and Henry III—were kings of France. But for his early death at age 30, he too would have been king.

François, Duke d'Anjou, portrait by François Clouet, 16th century; in the Condé Museum, Chantilly, Fr.

Giraudon from Art Resource. New York City

Catherine de Médicis gave him Alençon in 1566, and he bore the title of Duke d'Alençon until 1576. Small and swarthy, ambitious and devious, but a leader of the moderate Roman Catholic faction called the *Politiques*, he se-

cured in the general Treaty of Beaulieu (May 6, 1576) a group of territories that made him Duke d'Anjou. He also courted Elizabeth I of England and even succeeded in negotiating with her a marriage contract (1579), which, however, was never concluded, even after two wooing visits to London (1579, 1581–82). Seeking also to exploit the unsettled conditions in the Netherlands during the Dutch revolt against Spanish rule, he had himself proclaimed duke of Brabant and count of Flanders (1581), but the titles remained fictitious.

Anjou's death in 1584, during the reign of the childless Henry III, made his distant cousin the Protestant Henry of Bourbon-Navarre (the future Henry IV) heir presumptive to the crown of France.

• **Anjou, Philippe, Duke (duc) d'**: see Philip V under Philip (Spain).

Anjou, **HOUSE OF**: see Plantagenet, house of.

Ankara, formerly Europeanized as **ANGORA**, capital of Turkey, in the northwestern part of the country. It lies about 125 miles (200 km) south of the Black Sea, near the confluence of the Hatip, Ince Su, and Çubek streams.

While the date of the city's foundation is uncertain, archaeological evidence indicates habitation at least since the Stone Age, and a thriving Phrygian town was located in the area at the end of the 2nd millennium BC. Alexander the Great conquered Ankara in 334 BC, and in the 3rd century BC the town served as the capital of the Tectosages, a tribe of Galatia (the ancient name for the region around Ankara). In 25 BC Ankara was incorporated into the Roman Empire by the emperor Augustus.

The Atatürk Mausoleum, Ankara, Tur.

Robert Harding Picture Library London

As a city of the Byzantine Empire, Ankara was attacked by both the Persians and the Arabs. In about 1073 Ankara fell to the Seljuq Turks, but the crusader Raymond IV of Toulouse drove them out again in 1101. The Byzantines, however, were unable to maintain their control, and Ankara became a bone of contention between the Seljuqs and their rivals among the Turkish frontier lords. After 1143, Seljuq princes fought among themselves for possession of the city. With the establishment of the Seljuq Empire, Ankara declined.

In 1356 the city was captured by Orhan (Orkhan), the second Ottoman sultan; it became part of the Ottoman domains in 1360. It was besieged during the Anatolian campaign of Timur (Tamerlane), but in 1403 it again became subject to Ottoman rule. In subsequent centuries it regained its importance as a commercial and urban centre because of its location on the caravan route to the East.

After World War I, Mustafa Kemal Atatürk, the Turkish nationalist leader, made Ankara the centre of the resistance movement against both the government of the Ottoman sultan and the invading Greek forces; he established his headquarters there in 1919. Ankara was declared the capital of Turkey in 1923.

The architecture of the city reflects its varied history. Remains from the Roman era include a bath, the Column of Julian, and the Temple of Roma and Augustus. Byzantine remnants include the citadel and a cemetery. The square Alâeddin Mosque, with one minaret, is located near the walled citadel and dates from the Seljuq era. Ottoman buildings are numerous and include the Hacı Bayram Cami (1429), the Mahmud Pasa market (1464), and a 15th-century bazaar and caravansary that has been converted to house the Museum of Anatolian Civilizations. The modern city contains the huge Atatürk Mausoleum complex.

Government is the main business in the city, but Ankara is also Turkey's second most important industrial city after Istanbul. Factories producing wine and beer, flour, sugar, macaroni products, biscuits, milk, cement, terrazzo (mosaic paving), construction materials, and tractors are well established. Service and tourist industries are expanding rapidly.

Ankara is an important crossroads for trade and forms a major junction in the road network of Turkey. The city lies on the main east-west rail line across Anatolia. Esenboğa Airport, to the northeast, provides international services.

The city is the seat of the University of Ankara (established 1946), Hacettepe University (1206), and the Middle East Technical University (1956). The National Library is also located there, as are the state theatre and the Presidential Symphony Orchestra.

Several of Ankara's museums, which present a panorama of Anatolian history, are housed in renovated Ottoman buildings. The most important of these are the Museum of Anatolian Civilizations (with its world-renowned Hittite collection) and the Ethnographic Museum (with its holdings related to Turkish history, folklore, and art). The Atatürk Mausoleum contains the Atatürk Museum, which displays many of Atatürk's personal effects. Pop. (1997 prelim.) 2,984,099.

Ankara, Battle of, Ankara also spelled **ANGORA** (July 20, 1402), military confrontation in which forces of the Ottoman sultan Bayezid I were defeated by those of the Central Asian ruler Timur (Tamerlane) and which resulted in the collapse of Bayezid's hastily founded empire.

While challenging the Christian world in the West, Bayezid annexed the Anatolian Turkmen principalities and posed as heir to the Seljuqs of Anatolia. Meanwhile, Timur claimed suzerainty over these same principalities and gave refuge to the Turkmen princes defeated by Bayezid. The sultan, on his part, protected Timur's enemies, the Kara Koyunlu ("Black Sheep") and Jalâyirid rulers. Exasperated, Timur seized Sivas in central Anatolia (August 1400); Bayezid retaliated by capturing Timur's protégé, the ruler of Erzincan in eastern Anatolia. Finally the two rivals met at Çubukovasi, near Ankara, where Bayezid's Turkmen vassals deserted to Timur and the Ottomans were overwhelmed. The sultan himself was captured; he died in captivity in 1403.

Ankara, Treaty of, also called **FRANKLIN-BOUILLON AGREEMENT** (Oct. 20, 1921), pact between the government of France and the Grand National Assembly of Turkey at Ankara, signed by the French diplomat Henri Franklin-Bouillon and Yusuf Kemal Bey, the

Turkish nationalist foreign minister. It formalized the de facto recognition by France of the Grand National Assembly, rather than the government of the Ottoman sultan Mehmed VI, as the sovereign power in Turkey.

The Turkish government in Ankara had refused to ratify the Treaty of Sèvres (Aug. 10, 1920), which had been signed by the sultan and which had awarded parts of western Turkey to Greece; reaction to the treaty brought about a Turkish nationalist revival. After defeats by Turkish nationalists in southeastern Anatolia (Cilicia) in 1920–21, the French decided to withdraw southward and strengthen their forces in Syria and Lebanon. Under the terms of the Treaty of Ankara, the French agreed to evacuate Cilicia. A "special administrative regime" was established in Hatay (Alexandretta), and the Turkish-Syrian boundary was fixed.

The agreement assisted the Turkish nationalist cause by revealing differences between France and Great Britain, which continued to recognize the sultan's government in Istanbul, and by releasing Turkish nationalist forces from the southeastern front for fighting on the western front against the Greeks.

Ankaratra, volcanic mountainous region in central Madagascar (Malagasy), covering an area of approximately 2,000 square miles (5,200 square km) and rising to 8,671 feet (2,643 m) in Mount Tsiafajavona, the nation's second highest peak. The main range runs south-southwest from the town of Antananarivo. Antsirabe (*q.v.*), situated on the slopes of Mount Tsiafajavona, is the principal town in the region.

ankh, ancient Egyptian hieroglyph signifying "life," a cross surmounted by a loop and known in Latin as a *crux ansata* (ansate, or handle-shaped, cross). It is found in ancient tomb inscriptions, including those of the king Tutankhamen, and gods and pharaohs are of-

Ankh, ancient Egyptian hieroglyph signifying "life"

ten depicted holding it. The ankh forms part of hieroglyphs for such concepts as health and happiness. The form of the symbol suggests perhaps a sandal strap as its original meaning, though it has been seen as representing a magical knot. As a cross, it has been extensively used in the symbolism of the Coptic Christian church.

Ankhesenamun, original name ANKHESEN-PAATEN (fl. 2nd millennium BC), queen of Egypt (reigned 1332–1322 BC), who attempted a diplomatic coup after her husband Tutankhamen's death.

The third daughter of Akhenaton and Nefertiti, the rulers of the Amarna revolution, Ankhesenamun probably was married to her father about the 16th year of his reign. Although the marriage was primarily political, to secure Akhenaton's throne, a daughter was evidently born to Ankhesenamun.

At Tutankhamen's accession, Ankhesenamun was married to him, possibly in order to safeguard her position. When the king's name was altered to include Amon's name, so was hers. At Tutankhamen's unexpected death, Ankhesenamun entered into international negotiations to secure her position. According to Hittite archives, unwilling to associate herself with either of the likeliest Egyptian candidates, she sent a secret letter to the Hittite king, asking him for a son whom she would

make pharaoh. Because the Hittites had just completed a season's campaign against Egyptian forces in Syria, their ruler was astounded. Suspecting treachery, he sent an ambassador to learn the queen's true intent. In the spring of 1321 BC, his envoy and an Egyptian emissary arrived in the Hittite capital with Ankhesenamun's assurances and another more urgent plea. The Hittite ruler dispatched a son to Egypt, but the prince was intercepted and murdered, perhaps by Horemheb, Egypt's commander of armies and an aspirant to the throne.

An inscribed ring seen in Cairo in 1932 associates Ankhesenamun with Ay, her husband's former vizier and close adviser, who succeeded Tutankhamen. On Tutankhamen's stela of restoration, Ankhesenamun's figure was thoroughly erased a few years later by King Horemheb, who usurped the monument.

Anking (China): *see* An-ch'ing.

ankle, in humans, hinge-type, freely moving synovial joint between the foot and leg. The ankle contains seven tarsal bones that articulate (connect) with each other, with the metatarsal bones of the foot, and with the bones of the lower leg. The articulation of one of the tarsal bones, the ankle bone (talus, or astragalus), with the fibula and tibia of the lower leg forms the actual ankle joint, although the general region is often called the ankle. The chief motions of the ankle are flexion and extension. Like other synovial joints (those joints in which fluid is present), the ankle is subject to such diseases and injuries as bursitis and synovitis.

anklet, in jewelry, bracelet worn around the ankle. Ornamental anklets have been worn for centuries, particularly in the East. Jewelry found in Persia and dating from the end of the 2nd millennium to the 7th century BC includes anklets, some decorated with animals such as an ibex with curving horns. Anklets are still common in India, where they are sometimes adorned with jewels and bells and often hollowed and filled with shot, so as to jangle rhythmically when worn by dancers.

Ankobra, river in southern Ghana, western Africa. Rising northeast of Wiawso, it flows about 120 miles (190 km) south to the Gulf of Guinea (Atlantic) just west of Axim, commercial centre of the river basin. Its chief tributaries are the Mansi and the Bonsa rivers, and much of its basin is shared with the Tano River to the west. There are rapids in the upper reaches, but the Ankobra is navigable for 50 miles (80 km) upstream from its mouth and is tidal as far as Tomonto, with a 2-foot (0.6-metre) low- to high-tide difference.

Ankole, also spelled ANKORE (people): *see* Nkole.

ankyloglossia (congenital malformation): *see* tongue-tie.

Ankylosaurus, armoured herbivorous dinosaur of North America of the Late Cretaceous epoch (97.5 million to 66.4 million

Ankylosaurus

years ago). *Ankylosaurus*, moderately large, was about 5 m (15 feet) long. The hind limbs were larger than the forelimbs, indicating that *Ankylosaurus*, though it had evolved from bipedal ancestors, had reverted to a

quadrupedal pose. The back of the low, flat body was covered by bony plates that were pointed at the flanks of the animal; at the end of the rather long tail was a thick knob of bone that could have been used as a club. Close relatives of *Ankylosaurus* varied the armour theme somewhat, but all were formidable. In place of a bony club at the end of the tail, some forms had long, pointed bony spikes; in others, spikes of bone were present in the shoulder region.

Ann, Cape, cape on the Atlantic Ocean comprising the eastern extremity of Essex county, northeastern Massachusetts, U.S., 30 miles (48 km) northeast of Boston. Sheltering Ipswich Bay, it is indented by Annisquam Harbor on

Norman's Woe, off the east coast of Cape Ann, Massachusetts

© R. Terry Walker—The Picture Cube

the north and Gloucester Harbor on the south. Annisquam River, a 4-mile- (6.4-kilometre-) long navigable waterway, connects the two harbours. The cape also shelters the northern part of Massachusetts Bay, which extends south to Cape Cod.

The rocky, picturesque promontory, named for Queen Anne (wife of the British king James I), is noted for its quaint old fishing villages, resorts, and artists' colonies. Gloucester and Rockport (site of "Motif No. 1," a much-photographed and painted ancient fishing shed) are the main towns. Norman's Woe, a reef off the cape's east coast, has been the scene of numerous shipwrecks, the most celebrated being that of the *Hesperus*. Halibut Point forms Cape Ann's outermost tip.

Ann, Mother (Shaker leader): *see* Lee, Ann.

Law quadrangle, University of Michigan, Ann Arbor, Mich.

Mill and Joan Mann from CameraMann

Huron River. John Allen and Elisha W. Rumsey founded the community in 1824, which they named for their wives (both called Ann) and the local natural groves, or arbors. The settlement developed as an agricultural trading centre after the arrival in 1839 of the Michigan Central Railroad, which connected it with Detroit (38 miles [61 km] east). The University of Michigan (moved there in 1837 from Detroit, where it was founded in 1817) has played a major role in Ann Arbor's growth. Events of student interest dominate the life of the city, while a complex of hospitals and the university's medical school have made Ann Arbor a leading medical centre. Private industrial research and development joined by the university's various institutes of science and technology have raised Ann Arbor to rank as a major Midwest centre for aeronautical, space, nuclear, chemical, and metallurgical research. Diversified manufactures include ball bearings, scientific instruments, and precision machinery. Washtenaw Community College (1965) and Concordia (Lutheran) College (1962) are in the city. Inc. village, 1833; city, 1851. Pop. (1994 est.) city, 108,817; (1995 est.) Ann Arbor PMSA, 522,916.

Anna (personal name): *see under* Anne, except as below.

Anna, in full ANNA IVANOVNA (b. Jan. 28 [Feb. 7, New Style], 1693, Moscow, Russia—d. Oct. 17 [Oct. 28], 1740, St. Petersburg), empress of Russia from 1730 to 1740.

Daughter of Ivan V (reigned 1682–96) and niece of Peter I the Great (reigned 1682–1725), Anna was married to Frederick William, ruler of the Baltic seacoast duchy of Courland, on Oct. 31 (Nov. 11), 1710. Although her husband died on the journey to Courland after their wedding in St. Petersburg, Anna remained at Mitau (now Jelgava, Latvia), the capital of Courland, until 1730, when Peter II died and the Supreme Privy Council, the actual ruling body in Russia (1726–30), offered her the Russian throne.

Having accepted the council's proposal as well as its stipulation that she agree to certain "conditions" placing the real power of the state in the council's hands and effectively creating a limited monarchy in Russia, Anna proceeded to Moscow (February 1730, Old Style). But when she arrived and found widespread opposition to the council's conditions among the gentry and officers of the guard, she tore up the conditions (February 25), abolished the Supreme Privy Council, and reestablished the autocracy.

Anna Ivanovna, enameled miniature by an unknown artist, 18th century; in the collection of Mrs. Merriweather Post, Hillwood, Washington, D.C.
By courtesy of Hillwood Washington, D.C.

Anna, however, had little interest in government affairs and relied heavily on her lover, Ernst Johann Biron, and a small group of German advisers, including the head of Rus-

sia's foreign affairs, Andrey Osterman, and the chief of the army, Burkhard Münnich, to manage the state. While the empress concerned herself primarily with extravagant entertainments and crude amusements in the court at St. Petersburg, her favourites engaged Russia in the War of the Polish Succession (1733–35), which placed a pro-Russian king on the Polish throne, and in the Russo-Turkish War of 1736–39. The outcome of the Russo-Turkish War scarcely justified its tremendous cost in life and money, since the territory Russia gained by the war still left it lacking a warm-water outlet to the sea. In addition, Anna's ruling clique, which employed excessively brutal and repressive practices against its opponents, alienated the gentry, which resented domination by German officials. The increased expenditures of the court, combined with war expenses, led to a relentless extortion of taxes from the peasantry, whose social status steadily deteriorated in contrast with the advantages gained by the upper classes.

Shortly before her death Anna named as her successor Ivan, the son of her niece Anna Leopoldovna, and Biron as the infant's regent.

Anna, in full ANNA LEOPOLDOVNA (b. Dec. 7 [Dec. 18, New Style], 1718, Rostock, Mecklenburg [Germany]—d. March 7 [March 18], 1746, Kholmogory, Russia), regent of Russia (November 1740–November 1741) for her son, the emperor Ivan VI.

Anna Leopoldovna, detail of an engraving by J. Wagner after a portrait by N.A. Venetus, 18th century
Novosti Press Agency

A niece of Empress Anna (reigned 1730–40), Anna Leopoldovna married a nephew of the Holy Roman emperor Charles VI in 1739 and gave birth to a son, Ivan (Aug. 2 [Aug. 13], 1740), who was named heir to the Russian throne by Empress Anna in 1740, shortly before she died.

A few weeks later, however, the empress's appointed regent, Ernst Johann Biron, was arrested by certain members of the ruling German clique in Russia, led by Burkhard Münnich and Andrey Osterman. Münnich and Osterman appointed Anna Leopoldovna regent and assumed dominant positions in her government. But they were unpopular among the Russians, and, when they weakened the administration by quarreling with each other, Anna's major rival, Elizabeth, the daughter of Peter I the Great (reigned 1682–1725), staged a palace revolution (Nov. 25 [Dec. 6], 1741). Elizabeth imprisoned Anna and her family in 1742 and in 1744 exiled them to Kholmogory, where Anna died.

Anna COMNENA (b. Dec. 1, 1083—d. after 1148), Byzantine historian and daughter of the emperor Alexius I Comnenus. She is remembered for her *Alexiad*, a history of the life and reign of her father, which became a valuable source as a pro-Byzantine account of the early Crusades.

Anna received a good education, studying, among other subjects, literature, philosophy, history, and geography. She married the leader

of Bryennium, Nicephorus Bryennius (1097), and joined her mother, the empress Irene, in a vain effort to persuade her father, during his last illness, to disinherit his son, John II Comnenus, in favour of Nicephorus. Later conspiring to depose her brother after his accession to the throne (1118), Anna was, however, unable to obtain the support of her husband; the plot was discovered, and she forfeited her property, retiring to a convent, where she wrote the *Alexiad*. This work, in Greek, provides a picture of religious and intellectual activities within the empire, reflecting the Byzantine conception of the imperial office. It suffers from a defective chronology and excessive adulation of Alexius I.

Annaba, formerly BONE, or BONA, town and Mediterranean port, northeastern Algeria. It lies near the mouth of the Wadi Seybouse, close to the Tunisian border. Its location on a natural harbour (Annaba Gulf) between Capes Garde and Rosa early attracted the Phoenicians, probably in the 12th century BC. It passed to the Romans as Hippo Regius, was the residence of the Numidian kings, and achieved independence after the Punic Wars (264–146 BC).

Hippo Regius later became a centre of Christian thought, housing the Council of Hippo (AD 393) and forming the bishopric of St. Augustine (396–430). Destroyed by the Vandals in 431, Hippo Regius passed to the Byzantine emperor Justinian in 533, and about two centuries later (697) it was overcome by Arabs. An early centre of piracy, it remained one of the small cities of northern Africa under a succession of rulers until the French captured it in 1832. In 1848 it was created a *commune* administered from Paris.

Annaba rises from the shore up the cork-oak-covered slopes of the Edough foothills. The old town with its narrow streets dominates the centre of the city and is grouped around the Place du 19-Août and its early French houses and the Mosque of Salah Bey (1787). The 11th-century Mosque of Sidi Bou Merouan was built with columns taken from Roman ruins. The new town, built since 1870 along both sides of the thoroughfare Cours de la Révolution, contains the cathedral (1850) and basilica (1881) of Saint-Augustine, the chief public buildings, schools, the Hippo Museum, and public gardens. Annaba also is the site of a university (founded 1975) and has an international airport.

Annaba is Algeria's chief exporter of minerals, mainly iron ore and phosphates from the Tébessa deposits to the southeast. Surrounded by fertile farms (where wheat is grown), forests, and mines, it also serves as a trading and fishing port and port of call. It is connected by roads or rail lines to several other cities of northeastern Algeria and to Algiers. Annaba's major industries include an iron and steel complex, a fertilizer plant, automobile and railway shops, and aluminum works. Pop. (1987) 222,518.

Articles are alphabetized word by word, not letter by letter

annabergite, hydrated nickel arsenate mineral that is very similar to erythrite (*q.v.*).

annalist, any of the Roman historians prior to Livy (1st century BC–1st century AD) who drew up the conventional history of Rome from the foundation of the city. For their sources early Roman historians relied for the most part on the annual *tabulae pontificum*, or *annales*, which after 300 BC contained regular records of magistrates' names and public events of religious significance. The early Roman writer Quintus Ennius (239–169 BC) drew the title

of his epic poem from the *Annales*. The first Roman historians, among whom were Quintus Fabius Pictor, Cineius Alimentus, Postumius Albinus, and C. Aelius, wrote in the early 2nd century BC in Greek. They were followed by Marcus Porcius Cato (234–149 BC), whose *Origines* was the first history of Rome written in Latin. Under his influence, Lucius Cassius Hemina and L. Calpurnius Piso Frugi undertook more systematic reconstructions of Roman history, and about 123 BC P. Mucius Scaevola published in 80 books his *Annales maximi*, a systematic, year-by-year account of events in the Roman state that remained the model for subsequent annalistic accounts. The annalistic tradition was enshrined by Livy in his national history of Rome and influenced Tacitus in the composition of his *Annals*.

Annam, French-governed Vietnam or, more strictly, its central region, known in precolonial times as Trung Ky (Central Administrative Division). The term Annam (Chinese: "Pacified South") was never officially used by the Vietnamese to describe their country, even during the French colonial period.

The central section of Vietnam known to the French as Annam is largely a highland region extending from the Ma River southward to Ba Kiem Cape, which lies 47 miles (76 km) east-southeast of Ho Chi Minh City (formerly Saigon). The former imperial capital Hue has remained the chief cultural centre in the region.

Much of central Vietnam was under the control of the Cham empire until the expanding Vietnamese state defeated the Cham rulers in 1471, opening the way for steady Vietnamese movement toward the Mekong River delta. With the de facto division of Vietnam under the seigneurial Nguyen and Trinh families in the 16th century, Hue became the seat of the Nguyen. When Nguyen Anh, as the emperor Gia Long, united the whole of Vietnam in 1802, Hue became the imperial capital.

Central Vietnam came under French "protection" in 1883–85, leaving the court at Hue with only nominal power. In the confused immediate post-World War II period, Vietnam was temporarily divided at 16° N latitude, leaving parts of central Vietnam under different occupying authorities. Following the end of the first Indochina War in 1954, the temporary dividing line determined at the Geneva Conference again ran through central Vietnam, this time at the 17th parallel.

The predominant hills and plateaus of central Vietnam are occupied by a variety of hill peoples, some speaking variants of the Cham language, others using Mon-Khmer languages. The narrow, fertile coastal plain is occupied by the majority Vietnamese and is devoted largely to rice culture. The largest city in central Vietnam is Da Nang (*q.v.*), and its best anchorage is Cam Ranh Bay.

Annamese Cordillera, French CHAÎNE ANNAMITIQUE, Vietnamese TRUONG SON, principal mountain range of Indochina and the watershed between the Mekong River and the South China Sea. It extends parallel to the coast in a gentle curve generally northwest-southeast, forming the boundary between Laos and Vietnam. A fairly continuous range for about 700 miles (1,100 km), its rather precipitous eastern slopes leave a narrow coastal plain. Although its highest peak, Mount Linh, is only 8,524 feet (2,598 m) high, the range has few substantial passes, the most important being the Keo Nua Pass in northern Vietnam, part of a route between Muang Khammouan, Laos, and Vinh, Vietnam, and the Mu Gia Pass (*q.v.*).

The geologically complex range is constituted mainly of limestones, sandstones, granites, and gneisses in the north and in the south an

exposed, folded crystalline basement overlain in several places by basaltic lava flows. Among the plateaus created by these flows are the Bolovens Plateau in southern Laos and the Kontum and Dae Lac plateaus in southern Vietnam. To the south, the Annamese Cordillera begins to reverse itself, reaching 7,500 feet (2,300 m) or higher in peaks west of Nha Trang before terminating in the Saigon plain of southern Vietnam.

Annan, Kofi, in full KOFI ATTA ANNAN (b. April 8, 1938, Kumasi, Gold Coast [now Ghana]), Ghanaian international civil servant who in 1997 became the seventh secretary-general of the United Nations (UN). He was corecipient, with the UN, of the Nobel Prize for Peace in 2001.

Annan studied at the University of Science and Technology in Kumasi before enrolling at Macalester College in St. Paul, Minn., where he received a bachelor's degree in economics. He earned a master's degree while a Sloan Fellow at the Massachusetts Institute of Technology in 1971–72.

Annan began his career with the UN as a budget officer for the World Health Organization in Geneva in 1962. With the exception of a brief stint as the director of tourism in Ghana (1974–76), he spent his entire career with the UN, serving in several administrative posts. On March 1, 1993, he was elevated to under-secretary-general for peacekeeping operations. In that position, he distinguished himself during the civil war in Bosnia and Herzegovina, particularly in his graceful handling of the transition of peacekeeping operations from UN forces to NATO forces.

Boutros Boutros-Ghali, Annan's predecessor as secretary-general, had alienated some member nations, most notably the United States, with his independent and aloof style. Annan entered office with the tasks of repairing relations with the United States and reforming the UN bureaucracy.

Soon after becoming secretary-general, he introduced a reform plan to reduce the UN's budget and streamline its operations, moves that were welcomed by the United States. Other priorities included restoring public confidence in the UN, combating the AIDS virus, and ending human rights abuses. Annan was reappointed in 2001.

Annapolis, capital of the U.S. state of Maryland and seat of Anne Arundel county. The city lies along the Severn River at its mouth on Chesapeake Bay, 27 miles (43 km) southeast of Baltimore. Settled in 1649 as Providence by Virginian Puritans, it later was known as Town Land at Proctor's and Anne Arundel Town. In 1694 the colonial capital was moved there from St. Mary's City. The next year it was renamed to honour Princess Anne, who later, as queen, gave it a charter (1708). Annapolis patriots, like those of Boston, had a "tea party" on Oct. 19, 1774, forcing the owner of the brig *Peggy Stewart* to burn his ship and cargo of taxed tea. George Washington resigned (Dec. 23, 1783) as commander in chief of the Continental Army before the U.S. Congress in session there (Nov. 26, 1783, to June 3, 1784). The city avoided involvement in the battles of the American Revolution, the War of 1812, and the American Civil War, though many Civil War wounded were hospitalized there. The Annapolis Convention, held in 1786, was a precursor to the Constitutional Convention of 1787.

A port city, Annapolis has boatyards in Eastport and is the home port for a large number of private sailing vessels and other pleasure boats. The old waterfront area, with its city dock, once the home port for the Chesapeake oyster fleet, is now a yacht harbour. City life focuses largely on state government and the United States Naval Academy (*q.v.*). The academy (founded 1845), which occupies the site of old Fort Severn, has a 338-acre (137-

hectare) campus built on the river; the naval hero John Paul Jones is buried in its chapel crypt. The Naval Academy Museum displays relics of American naval history and has a large collection of ship models. Graduation of the midshipmen in late May is preceded by parades, concerts, and other events.

St. John's College was chartered (1784) as a continuation of King William's School (1696). The city's colonial heritage is preserved in many remaining buildings. The Colonial Annapolis Historic District contains the Maryland State House (1772–79), the oldest state capitol still in legislative use, where Congress ratified (Jan. 14, 1784) the Treaty of Paris ending the Revolution; the Old Treasury (1735–37); St. Anne's Episcopal Church (founded 1692); and more than 60 pre-Revolutionary houses, including the homes of three signers of the Declaration of Independence—William Paca, Samuel Chase, and Charles Carroll, Inc. 1708. Pop. (2000) 35,838.

Annapolis Academy: see United States Naval Academy.

Annapolis Convention, in U.S. history, regional meeting at Annapolis, Md., in September 1786; it was an important rallying point in the movement toward a federal convention to revise the inadequate Articles of Confederation.

Growing out of an earlier meeting of representatives of Maryland and Virginia to discuss ways of improving navigation on the Potomac River, the convention of delegates from five states found that it could not deal effectively with national commercial problems without changes in the Articles. Realizing that they could not recommend the needed revisions, the delegates stretched their authority by issuing a new call to all the states for a meeting eight months later in Philadelphia, where the present federal Constitution was drafted.

Annapolis Royal, formerly (until 1713) PORT ROYAL, town, seat of Annapolis county, southwestern Nova Scotia, Canada. The town lies at the mouth of the Annapolis River where it enters Annapolis Basin (an arm of the Bay of Fundy), 126 miles (203 km) by road west of Halifax. Founded in 1605 as Port Royal by the explorers Samuel de Champlain and Pierre du Gua, Sieur de Monts, it was the first French colony in North America and is Canada's oldest settlement. Destroyed by the British in 1613, it was later reconstructed and resettled by Scottish colonists, only to be turned over to the French in 1632 by the Treaty of Sainte-Germain-en-Laye. It was abandoned soon after, when the fort was moved to its present site about 6 miles (10 km) to the east.

The new settlement, repeatedly under British attack, was finally captured in 1710, formally ceded to the British by the Treaty of Utrecht (1713), and renamed Annapolis Royal in honour of Queen Anne. From then until the founding of Halifax in 1749, it served as the capital of Nova Scotia. Once an important lumbering, shipbuilding, and administrative centre, it is now a quiet market town and

The officer's quarters (1797) at Fort Anne National Historic Park, Annapolis Royal, Nova Scotia

James P. Rowan

tourist resort with apple growing, dairying, and sawmilling interests. The old Fort Anne (built 1687–1705), on the site of an older French fort built in 1636, is preserved within a national historic park, as is a reconstruction of the Port Royal Habitation (settlement) of 1605. Pop. (1991) 633.

Annapūrna, massif of the Himalayas in north-central Nepal, forming a ridge 30 miles (48 km) long between the basins of the Kāli Gandak and Marsyandi rivers. It contains four main summits, two of which, Annapūrna I (26,545 feet [8,091 m]) and II (26,040 feet [7,937 m]), stand at the western and eastern ends of the range, respectively; III (24,786 feet [7,555 m]) and IV (24,688 feet [7,525 m]) lie between them. Annapūrna I is one of the world's highest peaks. Although climbers had reached 28,150 feet (8,580 m) on Mount Everest in 1924, Annapūrna I became famous in 1950 as the first peak more than 26,000 feet (8,000 m) to be ascended to the summit. The feat was achieved by a French expedition led by Maurice Herzog, who with Louis Lachenal reached the top on June 3. Annapūrna IV was climbed on May 30, 1955, by H. Biller, H. Steinmetz, and J. Wellenkamp, and Annapūrna II on May 17, 1960, by R.H. Grant and C.J. Bonington in an expedition led by James O.M. Roberts. In 1970 an all-woman Japanese climbing team scaled Annapūrna III.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

annates, a tax on the first year's income (first fruits) from an ecclesiastical benefice given by a new incumbent either to the bishop or to the pope. The first mention of the practice appears in the time of Pope Honorius III (d. 1227). The earliest records show that the annates were sometimes a privilege conceded to the bishop for a term of years and sometimes a right based on immemorial precedent. Eventually popes claimed the privilege for themselves, at first only on a temporary basis to meet particular financial needs. Thus, in 1305 Clement V claimed the first fruits of all vacant benefices in England, and in 1319 John XXII claimed those of all of Christendom vacated within the next two years. The system was never applied uniformly or effectively throughout the church's territories and was the cause of much protest. Under the Annates Statute of 1534, Henry VIII claimed the English annates for the crown. Papal annates fell into disuse with the transformation of the system of benefices after the Council of Trent (1545–63).

From the time of Pope Benedict XIV (1740–58) the term has referred to the half portion (Latin *media annata*) of the first year's income from parochial benefices, which in Italy and the adjacent islands was to be contributed toward the restoration of the cathedral and collegiate churches of the respective dioceses.

annatto (*Bixa orellana*), tree native to the New World tropics and the only species of the family Bixaceae. Annatto grows up to 9 m (30 feet) tall and has rose-pink flowers about 5 cm (2 inches) wide and ovalish leaves about 8 to 18 cm long. The brown seed pods, about 5 cm long, yield a reddish or yellowish powder that is used in a dye for butter, cheese, and oleomargarine. The plant is cultivated in tropical and subtropical areas of the world.

Anne (personal name): *see under* Anna, except as below.

Anne (b. Feb. 6, 1665, London, Eng.—d. Aug. 1, 1714, London), queen of Great Britain from 1702 to 1714. The last Stuart monarch, she wished to rule independently, but her intellectual limitations and chronic ill health caused her to rely heavily on her ministers,

who directed England's efforts against France and Spain in the War of the Spanish Succession (1701–14). The bitter rivalries between Whigs and Tories that characterized her reign were intensified by uncertainty over the succession to her throne.

Anne was the second daughter of James, duke of York (King James II, 1685–88), and Anne Hyde. Although her father was a Roman Catholic, she was reared a Protestant at the insistence of her uncle, King Charles II. In 1683 Anne was married to the handsome, if uninspiring, Prince George of Denmark (1653–1708), who became her devoted companion. Of greater political consequence was Anne's intimate relationship with her childhood friend Sarah Jennings Churchill, wife of John Churchill (later 1st Duke of Marlborough). The beautiful, intelligent Sarah became Anne's lady of the bedchamber and soon had the princess in her power.

It was Sarah who persuaded Anne to side with the Protestant ruler William III of Orange, stadholder of the Netherlands, when William overthrew James II in 1688. By the Bill of Rights (1689), William and his wife Mary, Anne's elder sister, were made king and queen of England, and Anne was placed in line for the succession to the throne. Anne and Mary had a bitter falling-out, and after Mary's death in 1694 William cultivated Anne's goodwill, but he refused to appoint her regent during his absences from England.

Although Anne was pregnant 18 times between 1683 and 1700, only five children were born alive, and of these, only one, a son, survived infancy. His death in 1700 ended Anne's hopes of providing herself with a successor. Hence, she acquiesced to the Act of Settlement of 1701, which designated as her successors the Hanoverian descendants of King James I of England.

Anne became queen upon William's death in March 1702. From the first she was motivated largely by an intense devotion to the Anglican church. She detested Roman Catholics and Dissenters and sympathized with High Church Tories. At the same time, she sought to be free from the domination of the political parties. Her first ministry, though predominantly Tory, was headed by two neutrals, Sidney Godolphin and the Duke of Marlborough. The influence of Sarah Churchill (now Duchess of Marlborough) over Anne was slight after 1703, though the duke remained commander of the British forces.

Anne soon discovered that she disagreed with the Tories on strategy for the war; the queen, Marlborough, and the Whigs wanted to commit English troops to continental campaigns, while the Tories believed England should engage the enemy only at sea. Consequently, as Marlborough accumulated impressive victories on the Continent, pressure was exerted on Anne to admit Whigs to the ministry. She resisted obstinately and even grew cold toward the duchess, who adopted the cause of the Whig politicians. By 1707 the duchess had been supplanted in the queen's affections by Abigail Masham, the tool of the leading Tory, Robert Harley (later 1st Earl of Oxford). Nevertheless, the schemes of Harley and Masham caused Anne so much embarrassment that in 1708 she was forced to dismiss Harley and admit the most prominent Whigs into her administration. As the war dragged on, the nation turned against the Whigs. In 1710 Anne was able to expel them and appoint a Tory ministry. She dismissed both Marlboroughs from her service in 1711.

The queen's advancing age and her infirmities made the succession a crucial issue. Leading Tories were in constant communication with Anne's exiled Roman Catholic brother, James, the Old Pretender, who had been excluded by law from the succession. Nevertheless, the suddenness of Anne's final illness and death frustrated any plans the To-

ries might have had for capturing the throne for the Pretender. Her last act was to secure the Protestant succession by placing the lord treasurer's staff in the hands of a capable moderate, Charles Talbot, Duke of Shrewsbury, who presided over the peaceful accession of the Hanoverian prince George Louis (King George I, 1714–27).

Anne BOLEYN, Boleyn also spelled BULLEN (b. 1507?—d. May 19, 1536, London, Eng.), second wife of King Henry VIII of England and mother of Queen Elizabeth I. The events surrounding the annulment of Henry's marriage to his first wife, Catherine of Aragon, and his marriage to Anne led him to break with the Roman Catholic church and brought about the English Reformation.

Anne's father was Sir Thomas Boleyn, later Earl of Wiltshire and Ormonde. After spending part of her childhood in France, she returned to England in 1522 and lived at Henry's court

Anne Boleyn, drawing by Hans Holbein, c. 1534–35; in The British Museum

Copyright British Museum

and drew many admirers. A desired marriage with Lord Henry Percy was prevented on Henry's order by Cardinal Wolsey, and at some undetermined point the king himself fell in love with her.

In 1527 Henry initiated secret proceedings to obtain an annulment from his wife, the aging Catherine of Aragon; his ultimate aim was to father a legitimate male heir to the throne. For six years Pope Clement VII, under pressure from Henry's rival Charles V, refused to grant the annulment, but all the while Henry's passion for Anne was strengthening his determination to rid himself of his queen. About Jan. 25, 1533, Henry and Anne were secretly married. The union was made public on Easter of that year, and on May 23 Henry had the archbishop of Canterbury, Thomas Cranmer, pronounce the marriage to Catherine null and void. In September Anne gave birth to a daughter, the future queen Elizabeth I.

Anne's arrogant behaviour soon made her unpopular at court. Although Henry lost interest in her and began liaisons with other women, the birth of a son might have saved the marriage. Anne had a miscarriage in 1534, and in January 1536 she gave birth to a still-born male child. On May 2, 1536, Henry had her committed to the Tower of London on a charge of adultery with various men and even incest with her own brother. She was tried by a court of peers, unanimously convicted, and beheaded on May 19. On May 30 Henry married Jane Seymour. That Anne was guilty as charged is unlikely; she was the apparent victim of a temporary court faction supported by

Thomas Cromwell. A full biography is *Anne Boleyn* by Marie Louise Bruce (1972).

ANNE DE PISSELEU: see Étampes, Anne de Pisseleu, duchesse d' (duchess of).

ANNE OF AUSTRIA, French ANNE D'AUTRICHE (b. Sept. 22, 1601, Valladolid, Spain—d. Jan. 20, 1666, Paris), queen consort of King Louis XIII of France (reigned 1610–43) and regent during the opening years of the reign of her son King Louis XIV (from 1643).

The eldest daughter of King Philip III of Spain and Margaret of Austria, Anne was married to the 14-year-old Louis XIII in November 1615. Throughout his life Louis treated her with a cool reserve. In 1625 the English George Villiers, 1st duke of Buckingham, created a scandal at the French court by revealing his passion for the Queen. Her plight worsened as the powerful Cardinal de Richelieu, Louis XIII's chief minister from 1624 to 1642, sought to prevent her from exercising any influence over her husband. Anne took as her confidante the scheming Marie de Rohan-Montbazon, duchesse de Chevreuse. Anne and the queen mother, Marie de Médicis, failed in their attempt to persuade Louis to dismiss the Cardinal (the Day of Dupes, 1630).

After Richelieu declared war on Anne's brother, King Philip IV of Spain, in 1635, she remained sympathetic to the Spanish cause. Richelieu's spies kept her under surveillance, and in 1637 the Cardinal humiliated her by proving that she had been visiting the nunnery of Val-de-Grâce in order to conduct treasonable correspondence with Philip. Her status at court was enhanced, however, by the birth of her two sons, the dauphin Louis (the future Louis XIV) in 1638, and Philippe (later duc d'Orléans) in 1640. Through the provisions of his will, Louis XIII attempted to deprive her of her right to be sole regent for Louis XIV. Louis XIII died in May 1643, and shortly thereafter Anne had the will annulled by the Parlement of Paris.

As soon as she was declared sole regent, the leading nobles demanded the restoration of the privileges they had lost under Richelieu. Determined that her son should succeed to the absolute power that Richelieu had won for Louis XIII, she resisted these demands and took as her first minister the Italian-born Cardinal Jules Mazarin, one of Richelieu's most able associates. Anne and Mazarin were devoted to one another, and some historians have concluded that they were secretly married. Together they faced the series of revolts known as the Fronde (1648–53). The rebels forced Anne to dismiss Mazarin in February 1651, but, by faithfully following the Cardinal's instructions, she was able to divide her enemies. The rebellion virtually collapsed in October 1652, and Mazarin returned to Paris. Anne's regency officially ended in 1651,

when Louis XIV was proclaimed of age to rule. In 1659 France finally made peace with Spain, and the following year Louis XIV was married to Anne's niece, Marie-Thérèse, the daughter of Philip IV.

ANNE OF BEAUJEU: see Anne of France.

ANNE OF BRITTANY, French ANNE DE BRETAGNE (b. Jan. 25, 1477, Nantes, Fr.—d. Jan. 9, 1514, Blois), duchess of Brittany and twice queen consort of France, who devoted her life to safeguarding the autonomy of Brittany within the kingdom of France.

Daughter of Duke Francis II of Brittany and Margaret of Foix, Anne succeeded to her father's duchy on Sept. 9, 1488. The future of the duchy depended on her marriage. In desperation Anne allied herself with Maximilian of Austria, who married her by proxy on Dec. 19, 1490. King Charles VIII of France, fearful that Brittany might pass into the hands of a foreign power, attacked it, and Anne was

Anne of Brittany, portrait attributed to Jean (Jehan) Bourdichon; in a private collection

Giraudon—Art Resource/EB Inc

forced in the end to break with Maximilian and marry Charles (Dec. 6, 1491); the process of the union of Brittany with the French crown was thus begun.

Charles died in 1498 without issue, and Anne, in accordance with an agreement made at the time of their marriage, was married to his successor, Louis XII, on Jan. 8, 1499. The marriage contract declared that Brittany should eventually fall to the second son or to the eldest daughter of the marriage or, failing issue, to Anne's natural heirs; the special rights and privileges of the duchy were to be maintained.

For the remainder of her life, Anne, a woman of great intelligence, devoted herself to the administration of her duchy and jealously guarded its autonomy, but in the end her daughter Claude was betrothed (1506) to Francis of Angoulême, the future Francis I of France.

A patron of artists and poets, Anne commissioned a *Book of Hours* that is one of the most beautiful of French manuscripts. She also instituted the queen's maids of honour at the French court.

ANNE OF CLEVES (b. Sept. 22, 1515—d. July 16, 1557, London), fourth wife of King Henry VIII of England. Henry married Anne because he believed that he needed to form a political alliance with her brother William, duke of Cleves, who was a leader of the Protestants of western Germany. He thought the alliance was necessary because in 1539 it appeared that the two major Roman Catholic powers, France and the Holy Roman Empire, were about to join together to attack Protestant England. That threat prompted Henry's chief minister, Thomas Cromwell, to arrange the marriage to establish ties between England and the Lutheran enemies of the Holy Roman emperor, Charles V.

On Jan. 1, 1540, Anne arrived in England to meet her fiancé for the first time. Five days later the wedding took place. Henry was keenly disappointed, Anne being less attractive than he had been led to expect, and he soon

came to resent her lack of sophistication and limited command of the English language.

When the alliance between the Catholic powers failed to materialize, the marriage became a political embarrassment and was annulled by an Anglican convocation (July 9, 1540). Anne acquiesced and was rewarded with a large income, on the condition that she remain in England. She lived at Richmond or Bletchingley, with occasional visits to court, until her death.

ANNE OF DENMARK (b. Dec. 12, 1574—d. March 2, 1619), queen consort of King James I of Great Britain (James VI of Scotland); although she had little direct political influence, her extravagant expenditures contributed to the financial difficulties that plagued James's regime.

The daughter of King Frederick II of Denmark and Norway, Anne was married to James in 1589. Her Lutheran upbringing and frivolous nature cost her the affection of James's Scottish Presbyterian subjects, and James alienated Anne by entrusting the upbringing of their first son, Prince Henry (1594–1612), to John Erskine, 2nd earl of Mar. Nevertheless, after James ascended the British throne in 1603, he and Anne lived in harmony, although they had separate quarters during the last few years of her life. Most of the Queen's time and energy were devoted to lavish court entertainments, and her patronage contributed to the development of the arts, particularly of the masque. She embarrassed

Anne of Denmark, detail of an oil painting after Paul van Somer, 1617; in the National Portrait Gallery, London
By courtesy of the National Portrait Gallery, London

James, however, by displaying sympathy for Roman Catholicism. Their second son succeeded James as King Charles I (ruled 1625–49). A biography, *Anne of Denmark*, by E.C. Williams, was published in 1970.

ANNE OF FRANCE, also called ANNE OF BEAUJEU (b. 1461—d. Nov. 14, 1522, Chantelle, Fr.), eldest daughter of Louis XI of France and Charlotte of Savoy, who exercised, with her husband, Pierre de Bourbon, seigneur de Beaujeu, a virtual regency in France from 1483 to 1491, during the early years of the reign of King Charles VIII.

Anne's energy, strength of will, cunning, and political sense enabled her to overcome the difficulties threatening the kingdom, the most important of which was unrest among the magnates, who had suffered under Louis XI's callous oppressions. Concessions were made: many of Louis's favourites were sacrificed; lands were restored to hostile nobles, among whom was the Duc d'Orléans, the future Louis XII of France; and the States General were convened (1484). When the Beaujeus ignored that assembly's demand to control taxation and hold regular meetings, the "Mad War" broke out between, on the one side, the crown

Anne of France, detail from a portrait by an unknown artist, c. 1498; in the cathedral of Moulins, Fr.

Giraudon—Art Resource

and, on the other, the Duc d'Orléans and Francis II of Brittany, which ended in a royal victory.

In 1491, despite Austrian and English opposition, the Beaujeus concluded the marriage of Charles VIII with Anne of Brittany, which joined the domains of Brittany with the crown. When Charles freed himself from tutelage, however, his former guardians were exposed to the wrath of the new queen, whose duchy's independence had been compromised.

Anne of France had been the dominant party in the Beaujeu marriage. When Pierre died in 1503, Anne remained administrator of his Bourbon lands, protecting them from royal encroachment.

Anne and Joachim, SAINTS (fl. 1st century BC, Palestine; Western feast day July 26, Eastern feast day July 25), the parents of the Virgin Mary, according to tradition derived from certain apocryphal writings. Information concerning their lives and names is found in the 2nd-century-AD *Protevangelium of James* ("First Gospel of James") and the 3rd-century-AD *Evangelium de nativitate Mariae* ("Gospel of the Nativity of Mary"). According to these sources, Anne (Hebrew: Hannah) was born in Bethlehem, Judaea. She married Joachim, and, although they shared a wealthy and devout life at Nazareth, they eventually lamented their childlessness. Joachim, reproached at the Temple for his sterility, retreated into the countryside to pray, while Anne, grieved by his disappearance and by her barrenness, solemnly promised God that, if given a child, she would dedicate it to the Lord's service. Both received the vision of an angel, who announced that Anne would conceive and bear a most wondrous child.

The couple rejoiced at the birth of their daughter, whom Anne named Mary. When the child was three years old, Joachim and Anne, in fulfillment of her divine promise, brought Mary to the Temple at Jerusalem, where they left her to be brought up. This event became so important in church doctrine that by 1585 Pope Sixtus V included in the Western church calendar the liturgical feast of the Presentation of the Virgin Mary (November 21). Although this festival originated early in the East, probably at Jerusalem in 543, its first Western observance was recorded in England in the 11th century.

The account of their lives startlingly parallels the Old Testament story of the barren Hannah and her conception of Samuel (1 Samuel 1). According to later legends, Joachim died shortly after Mary's birth, and Anne, encouraged by the Holy Spirit, remarried. Anne's cult was fervent in the Eastern church as early as the 4th century, and in the early 8th century Pope Constantine probably introduced

her devotion to Rome. Joachim's cult was introduced to the West in the 15th century.

The *Protevangelium* became the foundation for establishing the liturgical feasts of the Nativity of the Virgin Mary (September 8) and the Immaculate Conception of the Blessed Virgin Mary (December 8). Many churches, the first dating from the 6th century, were built in Anne's honour. Anne's cult became extremely popular in the Middle Ages and influenced such theologians as Jean de Gerson, Konrad Wimpinar, and Johann Eck (who endorsed the interpolation that Anne in her alleged subsequent marriages became the grandmother of the Apostles John and James [sons of Zebedee], Simon, Jude [Judas], James, son of Alphaeus, and also of James ["the Lord's brother"]). Martin Luther and others vehemently attacked the cult of Anne, which was then promoted by post-Reformation popes. Eastern literature on Anne, going back to the 4th century, does not follow the fantastic legends of medieval Western tradition. Anne is the patron saint of Brittany and Canada and of women in labour.

BIBLIOGRAPHY. Kathleen Ashley and Pamela Sheingorn (eds.), *Interpreting Cultural Symbols: Saint Anne in Late Medieval Society* (1990), covers the fields of art history, literature, religion, and social history.

annealing, treatment of a metal or alloy by heating to a predetermined temperature, holding for a certain time, and then cooling to room temperature to improve ductility and reduce brittleness. Process annealing is carried out intermittently during the working of a piece of metal to restore ductility lost through repeated hammering or other working. Full annealing is done to give workability to such parts as forged blanks destined for use in the machine-tool industry. Annealing is also done for relief of internal stresses. Annealing temperatures vary with metals and alloys and with properties desired but must be within a range that prevents the growth of crystals.

Anney, city, capital of Haute-Savoie *département*, Rhône-Alpes *région*, southeastern France. It lies along the northwestern shore of Lake Annecy at the entrance to one of the cluses (transverse gorges) of the Savoy Pre-Alps, south of Geneva. Traces of the Gallo-Roman *Boutae* have been found nearby. The seat of the counts of Genevois from the 10th century, Annecy was attached to the dukedom of Savoy from 1401 and became important during the Reformation when the bishop's seat was transferred there from Geneva in 1535 along with monastic institutions expelled from Geneva during the Reformation. St. Francis de Sales was bishop (1602–22) and, with St. Jane Frances Chantal, founded the first Convent

Canal in the old quarter of Annecy, Fr.

Yves Dejaridin from Rapho/Photo Researchers

of the Visitation of the Virgin in Annecy. In 1728 the 16-year-old Jean-Jacques Rousseau took refuge in the city. Annecy, along with the rest of Savoy, became part of France in 1860. The old part of the city has arcaded streets that are interlaced with canals. Tourism is an economic mainstay; the city's industries include electronics, confections, and precision instruments. Pop. (1990) 51,143.

annelid, phylum name ANNELIDA, also called SEGMENTED WORM, any member of a phylum of invertebrate animals that are characterized by the possession of a body cavity (or coelom), movable bristles (or setae), and a body divided into segments by transverse rings, or annulations. Comprising more than 9,000 species, the annelids are divided into three classes: polychaetes, or marine worms; oligochaetes, or earthworms; and hirudineans, or leeches.

A brief treatment of annelids follows. For full treatment, see MACROPAEDIA: Annelids.

The polychaetes, or annelids of the class Polychaeta, number more than 6,000 species and are found worldwide, most often in marine environments. They are divided between free-living and sedentary (tube-dwelling) forms. They range in length from less than an inch to more than 20 feet (6 m). Free-living polychaetes have bodies made up of a head (or prostomium), a segmented trunk, and a tail (or pygidium); sedentary polychaetes have a head (which may be distinct or indistinct), gills (in most species), thoracic and abdominal regions, and a tail. Respiration occurs either through gills or the body wall, and the digestive system usually consists of a mouth, an esophagus, an intestine, and an anus.

Parasitism is rare in polychaetes, although commensalism is common among the scale worms (order Phyllodocida). The polychaetes exhibit occasional aggressive behaviour, and some species are capable of producing light (bioluminescence), a trait often related to sexual maturity. Both polychaetes and oligochaetes have shown a rudimentary ability to learn by experience.

Polychaetes reproduce sexually, though a few sedentary species are known to reproduce asexually, and hermaphroditism is rare. Reproduction is generally accomplished by the shedding of gametes (sperm and eggs) directly into the water. Fertilized eggs develop into diamond-shaped, free-swimming larvae called trochophores, which gradually come to resemble adults once they settle on a suitable surface. Most species are capable of regenerating lost body parts, particularly tails.

The oligochaetes, of the class Oligochaeta, number approximately 3,250 species and are generally found dwelling in the soil, although a few species live in aquatic environments. The range of their length compares with that of the polychaetes; their bodies are made up of a head and a cylindrical trunk, which is divided into as many as 600 segments. Setae project from the bottom, or ventral, side of the body. Respiration takes place through the body wall in most oligochaetes, and their digestive systems usually consist of a mouth, a muscular pharynx, an esophagus, a muscular gizzard, a long intestine, and an anus. Oligochaetes move by extending the anterior (front) end of the body, anchoring the extended part with setae, and then contracting the posterior end of the body.

At sexual maturity a saddle-shaped thickening in the centre of the body, called a clitellum, is present. Oligochaetes are primarily hermaphroditic, and copulation usually takes place with a pair of worms in a head-to-tail position, simultaneously exchanging sperm and eggs. The clitellum secretes a cocoon, into which are inserted eggs as it passes over the female pores and sperm as it passes over the

male pores. The entire development of the young worm takes place inside this cocoon. Aquatic species are often capable of a form of asexual reproduction, in which the body of the worm fragments into segments that then grow into new worms, and some species can lay self-fertilized eggs or reproduce by parthenogenesis. Regeneration is common.

The leeches, of the class Hirudinea, number about 300 species and are generally found in freshwater or humid environments. They are elliptical in shape, with 34 segments each and a sucker at both ends of the body (the larger sucker on the posterior end). They can reach lengths of up to 16 inches (40 cm). Respiration occurs through the skin, and leech digestive systems usually consist of a mouth surrounded by the front sucker, an esophagus, a crop, an intestine, a rectum, and an anus.

All leeches feed on blood. All are hermaphroditic, and their reproduction is always sexual. Eggs are deposited in cocoons secreted by the clitellum, and the entire development of the young leech takes place inside this cocoon. The mode of locomotion consists in anchoring of a sucker, contraction of muscles, and then attachment of the other sucker.

The annelids are important to humankind in several ways. Polychaetes turn over sediment on the bottom of the ocean, while oligochaetes such as the earthworm (*Lumbricus terrestris*) turn over terrestrial soil. The bloodworm (*Glycera dibranchiata*), a polychaete, is used as saltwater fish bait. The sludge worm *Tubifex*, which is an oligochaete, grows near sewer outlets and is used as an indicator of water pollution, as well as food for tropical fish. Earthworms are used as freshwater fish bait and as humus builders in gardens. Leeches have a long history of medical use, and even today, hirudin, an extract made from leeches, is used as a blood anticoagulant.

Annenberg, Walter H., in full WALTER HERBERT ANNENBERG (b. March 13, 1908, Milwaukee, Wis., U.S.—d. Oct. 1, 2002, Wynnewood, Pa.), publisher, philanthropist, and art collector who served as U.S. ambassador to Britain from 1969 to 1974.

Annenberg was the only son of Moses Annenberg (1878–1942), a poor immigrant from East Prussia who became the millionaire publisher of *The Philadelphia Inquirer* and the horse-racing publications *Daily Racing Form* and *Morning Telegraph*. In 1939 Moses Annenberg was indicted for tax evasion and bribery. Walter was also indicted, but the charges against him were dropped. When his father died shortly after being paroled in 1942, Walter inherited the debt- and scandal-ridden Triangle Publications, Inc. He successfully took the company in new directions—founding the magazine *Seventeen* (1944), acquiring several television and radio stations, and developing *TV Guide* (1953), which became one of the most popular magazines in the United States. In 1988 Annenberg sold his interests in Triangle for a reported \$3.2 billion.

Annenberg was also renowned for his collection of Impressionist and Postimpressionist paintings and for his philanthropy. He donated millions to various museums, libraries, schools, and hospitals, as well as establishing the charitable M.L. Annenberg Foundation and the Annenberg School for Communication at both the University of Pennsylvania and the University of Southern California.

annexation, a formal act whereby a state proclaims its sovereignty over territory hitherto outside its domain. Unlike cession, whereby territory is given or sold through treaty, annexation is a unilateral act made effective by actual possession and legitimized by general recognition.

Annexation is frequently preceded by con-

quest and military occupation of the conquered territory. Occasionally, as in the German annexation of Austria in 1938, a conquest may be accomplished by the threat of force without active hostilities. Military occupation does not constitute or necessarily lead to annexation. Thus, for instance, the Allied military occupation of Germany after the cessation of hostilities in World War II was not followed by annexation. When military occupation results in annexation, an official announcement is normal, to the effect that the sovereign authority of the annexing state has been established and will be maintained in the future. Israel made such a declaration when it annexed the Golan Heights in 1981. The subsequent recognition of annexation by other states may be explicit or implied. Annexation based on the illegal use of force is condemned in the Charter of the United Nations.

Conditions may exist which obviate the necessity for conquest prior to annexation. In 1910, for example, Japan converted its protectorate of Korea into an annexed colony by means of proclamation. Preceding its annexation of the Svalbard Islands in 1925, Norway eliminated its competitors by means of a treaty in which they agreed to Norwegian possession of the islands. Annexation of Hawaii by the United States in the late 19th century was a peaceful process, based upon the willing acceptance by the Hawaiian government of U.S. authority.

The formalities of annexation are not defined by international law; whether it be done by one authority or another within a state is a matter of constitutional law. The Italian annexation of Ethiopia in 1936 was accomplished by a decree issued by the king of Italy. Joint resolutions of Congress were the means by which the United States annexed Texas in 1845 and Hawaii in 1898. *See also* conquest.

annihilation, in physics, reaction in which a particle and its antiparticle collide and disappear, releasing energy. The most common annihilation on Earth occurs between an electron and its antiparticle, a positron. A positron, which may originate in radioactive decay, usually combines briefly with an electron to form a quasi-atom, called positronium, composed of the two particles spinning around each other before they collide. After annihilation, two or three gamma rays (similar to X rays) radiate from the point of collision.

The amount of energy (E) produced by annihilation is equal to the mass (m) that disappears multiplied by the square of the speed of light in a vacuum (c)—i.e., $E = mc^2$. Thus annihilation is an example of the equivalence of mass and energy and a confirmation of the special theory of relativity, which predicts this equivalence.

Other annihilation reactions also occur. Nucleons (protons and neutrons), for example, annihilate antinucleons (antiprotons and antineutrons), and the energy is carried away as pions and kaons, particles in the class of mesons. Annihilation of matter and antimatter has been invoked by some cosmologists to explain the enormous energy of quasars (quasi-stellar sources) and to explain the apparent expansion of the universe.

Anniston, city, seat (1899) of Calhoun county, eastern Alabama, U.S. It lies in the foothills of the Appalachian Mountains. Founded in 1872 by Samuel Noble, Daniel Tyler, and Tyler's sons as a private industrial community (opened to the public in 1883), it was originally named for the Woodstock Iron Company; to avoid confusion with another Woodstock in Alabama, it was renamed Anniston (Annie's Town) for the wife of Alfred Tyler, the company president. Metal products and textiles are the city's major manufactures. The Anniston Museum of Natural History has a notable collection of bird specimens, and the Berman Museum showcases military-related

artifacts. Fort McClellan (1917–99) was the headquarters of the Women's Army Corps (1942–78) from 1954. Jacksonville State University is 13 miles (21 km) north of Anniston in Jacksonville, Inc. 1883. Pop. (2000) city, 24,276; Anniston MSA, 112,249.

Anno, SAINT, Anno also spelled HANNO (b. c. 1010, Swabia—d. Dec. 4, 1075; canonized 1183; feast day December 4), archbishop of Cologne who was prominent in the political struggles of the Holy Roman Empire.

Educated at Bamberg, Anno became confessor to the Holy Roman emperor Henry III, who appointed him archbishop in 1056. He was the leader of the party that abducted the young king Henry IV from his mother, Agnes of Poitou. Anno then seized the regency but was compelled to share it with Adalbert, the powerful archbishop of Hamburg-Bremen. In 1064 he left the court but recovered some of his former influence over Henry when Adalbert fell from favour in 1066. Anno's most important service was at the Council of Mantua (May 1064), when he succeeded in having Alexander II recognized as pope against the antipope Honorius II. Anno retired to a life of strict penance at the Abbey of Siegburg, which he had founded in 1064.

anno mundi (Latin: "in the year of the world"), abbreviation AM, the year dating from the year of creation in Jewish chronology, based on rabbinic calculations. Since the 9th century AD, various dates between 3762 and 3758 BC have been advanced by Jewish scholars as the time of creation, but the exact date of Oct. 7, 3761 BC, is now generally accepted in Judaism. However, critical dates that underlie the calculations are uncertain. Rabbis used the genealogy in Genesis to calculate the date of the creation and then added to their calculations the time that had elapsed since the time of Genesis. Despite the uncertainties, many Jews use this dating system as a sign of attachment to tradition.

Annobón, also called PAGALU, volcanic island in the South Atlantic Ocean near the Equator; it is part of Equatorial Guinea. Located about 350 miles (565 km) southwest of continental Equatorial Guinea, it occupies an area of 7 square miles (17 square km) and rises to an elevation of 2,200 feet (671 m). Fishing and lumbering activities are centred in San Antonio, the chief settlement.

Annonaceae, the custard-apple, or annona, family, the largest family of the magnolia order (Magnoliales). According to some authorities, it contains 122 genera and 1,100 species. Many species are valuable for their large, pulpy fruits, some are useful for their timber, and others are prized as ornamentals. The family consists of trees, shrubs, and woody climbers found mainly in the tropics, although a few species extend into temperate regions.

Leaves and wood are often fragrant. Leaves are simple, with smooth margins, and alternately arranged in two rows along the stems. The radially symmetrical flowers are usually bisexual. In most species the three sepals are united at the base. There are six brown or yellow petals, many stamens in a spiral, and many pistils, each with a one-chambered ovary containing many ovules. The fruit is a berry. Flowers in some species are borne directly on large branches or on the trunk.

Bark, leaves, and roots of many species are important in folk medicine, and others bear edible fruits or are important sources of perfume and spice.

A handsome ornamental of the family is the weeping form of the mast tree (*Polyalthia longifolia pendula*), of Sri Lanka. Its shining, brilliant green, willowy, wavy-edged leaves hang from pendant branches that almost clasp the tall, straight trunk. The leaves are used as temple decorations in India.

A South American tree, *Porcelia saffordiana*, bears immense fruits sometimes weighing 18 kg (40 pounds) or more.

The alligator apple (*Annona glabra*) of tropical America and western Africa, also known as pond apple and corkwood, is a 12-metre (40-foot) evergreen with 18-centimetre- (7-inch-) long oval leaves and fragrant yellowish flowers. It bears smooth, gnarled, yellowish fruits, 5–10 cm long, which are edible but of poor flavour. Its roots are used to make bottle corks and fishing floats and as rootstock for grafting less hardy species of *Annona*.

The custard apple (*A. reticulata*), a small, tropical American tree, gives the family one of its common names. Also known as bullock's-heart for its globose shape, it has fruits with creamy white, sweetish, custard-like flesh.

annual aster: see China aster.

annuity, in the most literal sense, a payment made yearly, as, for example, under a contract to provide retirement income. The term is also applied to any series of periodic payments made at regular, fixed intervals; the length of the interval is called the annuity period.

There are two main classes of annuities: annuities certain and contingent annuities. Under an annuity certain, the payments are to continue for a specified number of payments, and calculations are based on the assumption that each payment is certain to be made when due. With a contingent annuity, each payment is contingent on the continuance of a given status, as with a life annuity under which each payment is contingent on the survival of one or more specified persons.

A special case of the annuity certain is the perpetuity, which is an annuity that continues forever. Perhaps the best-known example of a perpetuity is the interest payment on the British government bonds known as consols. Because these obligations have no maturity date, it is intended that the interest payments will continue indefinitely.

The contingent annuity used in life insurance and pension plans is based upon the risk-sharing principle. The price of an annuity paying a given sum for life is based upon the life expectancy of the annuitant at the time the annuity is to begin. In effect, the annuitant joins with a large number of other persons of the same age in establishing a fund that is calculated, on the basis of mortality tables, to be sufficient to pay each person the life income agreed upon. Some will live longer than others and receive more in payments than they have put into the fund, whereas others will not live long enough to receive all that they have put in. This risk-sharing principle makes it possible to purchase an annuity that guarantees much higher payments than could be obtained if the same sum of money were invested at interest. It has the disadvantage that upon the death of the annuitant nothing is left for his heirs.

annulment, legal invalidation of a marriage. Annulment announces the invalidity of a marriage that was void from its inception. It is to be distinguished from dissolution, which ends a valid marriage for special reasons—e.g., insanity of one partner after marrying. The annulment decree attempts to leave the parties *in statu quo ante* (as they were before the marriage), unless doing so would adversely affect a third person.

In secular law, only the government, through its courts, can invalidate a marriage; and generally only a party to the marriage can seek annulment. Christian canon law also has procedures for invalidating marriages.

To justify annulment, there must be a defect in the marriage contract—e.g., incompetence of one party because of age, insanity, or a pre-existing marriage. Continued absence of one party also justifies annulment. Thus, in some places, one party may get an annulment if

the other is sentenced to a long prison term. Generally, annulment is easier if the marriage is unconsummated.

In annulment lawsuits, the validity of the marriage must be clearly disproved. The so-called clean hands doctrine figures heavily in such cases, meaning that the conduct of the person seeking the annulment must be fair and above suspicion if he is to prevail. Thus, a party who knew the partner was underage but proceeded with the marriage would probably be denied annulment.

Annunciation, in Christianity, the announcement by the angel Gabriel to the Virgin Mary that she would conceive a Son of the Holy Spirit to be called Jesus (Luke 1:26–38).

The Feast of the Annunciation, one of the principal feasts of the Christian church, is celebrated on March 25 (Lady Day). The first authentic allusions to the feast (apart from

flexibility depend on the type, concentration, and temperature of the electrolyte, the strength of the electrical current and the processing time, and the type of metal being plated. In the most common type of anodizing, which uses a 15 percent sulfuric acid bath, dyes can be introduced into the oxidation process in order to achieve a coloured surface. Aluminum that has been anodized and coloured in this way is used widely in giftware, home appliances, and architectural decoration.

anointment, ritual application of oil or fat to the head or body of a person or to an object; an almost universal practice in the history of religions, although both the cultic practice followed and the sacred substance employed vary from one religion to another. It is possible to

"The Annunciation," centre panel of the "Mérode Altarpiece" by Robert Campin, c. 1428; in The Cloisters, Metropolitan Museum of Art, New York

By courtesy of the Metropolitan Museum of Art, New York, The Cloisters Collection, Purchase

the Gelasian and Gregorian sacramentaries, in both of which it is mentioned) are in acts of the Council of Toledo (656) and of the Trullan Council (692).

Because its significance is much more than narrative, the Annunciation had a particularly important place in the arts and church decoration of the early Christian and medieval periods and in the devotional art of the Renaissance and Baroque. Moreover, because, in Christian doctrine, the event coincides with the Incarnation of Christ, it also represents a prelude to the redemption of the world.

anoa: see buffalo.

anode, the terminal or electrode from which electrons leave a system. In a battery or other source of direct current the anode is the negative terminal, but in a passive load it is the positive terminal. For example, in an electron tube electrons from the cathode travel across the tube toward the anode, and in an electroplating cell negative ions are deposited at the anode. *Compare* cathode.

anodizing, method of plating metal for such purposes as corrosion resistance, electrical insulation, thermal control, abrasion resistance, sealing, improving paint adhesion, and decorative finishing. Anodizing consists of electrically depositing an oxide film from aqueous solution onto the surface of a metal, often aluminum, which serves as the anode in an electrolytic cell. Plate properties such as porousness, abrasion resistance, colour, and

recognize three distinct, though not separate, meanings ascribed to ritual anointments by the devotees of various religions.

Anointment as healing. The medicine man of a tribe may be both its priest and its physician; "salvation" literally means "healing" or restoration to soundness. In the practice of ritual anointing, this conjunction of religion and medicine is clear. Anointment seems intended to apply the power of natural and supernatural forces to the sick and thus to ward off the baneful influences of diseases and of demons.

Anointment as consecration. In preparation for battle, in danger from wild animals, in the hour of death, and at other special times, anointment is used to endow an ordinary person with special holiness. He is "set aside" for a particular relation to that which is regarded as holy and good. Anointment as consecration is frequently applied not only to persons but also to objects. Altars, sacred vessels, temples, and sometimes even weapons and items of clothing are anointed to dedicate them to the service of the divine and to assure and symbolize the presence and pleasure of the divine in the holy place. In the Roman Catholic and Eastern Orthodox churches, the ritual anointing of the seriously ill and the elderly has been practiced as a sacrament since early times. In the Roman Catholic Church, unction was long regarded as a last rite, usually postponed until death was imminent and the dying Christian was *in extremis*; thus, the name extreme unction developed. In modern times, a more lenient interpretation permitted anointing of

the less seriously ill. In the Eastern Orthodox churches the name extreme unction was never used, and the healing aspects of the sacrament have been considered most important. In the Greek Orthodox Church the sacrament is sometimes administered to well persons to prevent illness.

Anointment as ordination. Over and above the consecration applied to ordinary men, anointment has a place in the particular rituals by which certain men receive positions of eminence. In many religions priests are inducted into their sacred office with a holy chrism (*q.v.*). In ancient Israel and in various Christian cultures, the king was anointed in the rite of coronation as the one chosen by God to rule over the people.

anole, any of about 250 species of lizards in the large arboreal (tree-dwelling) genus *Anolis* (family Iguanidae). They occur throughout the warmer regions of North and South America and are abundant in the West Indies. Like the gecko (*q.v.*), all anoles have enlarged finger and toe pads that are covered with microscopic hooks. These clinging pads, together with sharp claws, enable them to climb, even over the smoothest surface, with great speed and agility. Anoles attain 12 to 45 centimetres (5 to 18 inches) in length and can change colour from brown or yellow to several shades of green. The male often has a large red or yellow expansible dewlap (fold of skin in the neck region).

The most familiar anole (*A. carolinensis*, or green anole, commonly but erroneously called chameleon) is native to the southern United

Green anole (*Anolis carolinensis*)

Robert J. Erwin—The National Audubon Society Collection/Photo Researchers

States and islands in the Caribbean; it is the false "chameleon" sold in pet shops. Its colour varies at times from green to brown or mottled, but its colour-changing ability is poor compared to that of the true chameleons of the Old World. Green anoles reach a maximum length of 18 centimetres and have a pink dewlap.

anomaly, in astronomy, originally the nonuniform (anomalous) apparent motions of the planets. In present usage, three kinds of anomaly are distinguished to describe the position in the orbit of a planet, a satellite, or a star (in a binary system) around the centre of mass. The following text relates to the orbit of a planet. True anomaly is the angle, V , between lines drawn from the centre of mass (near the centre of the Sun, S), to a planet P , and to the perihelion point B , where the planet comes closest to the Sun. The mean anomaly is the angle between lines drawn from the Sun to the perihelion B and to a point (not

Anomaly

Encyclopædia Britannica, Inc.

shown) moving in the orbit at a uniform rate corresponding to the period of revolution of the planet. The eccentric anomaly is the angle E , between the perihelion B , the centre of the ellipse at C , and the point P' , which is located by drawing a perpendicular to AB passing through the planet and intersecting a circle of diameter AB .

anomie, also spelled ANOMY, in societies or individuals, a condition of instability resulting from a breakdown of standards and values or from a lack of purpose or ideals.

The term was introduced by the French sociologist Émile Durkheim in his study of suicide. He believed that one type of suicide (anomic) resulted from the breakdown of social standards that people need to regulate their behaviour. When a social system is in a state of anomie, common values and common meanings are no longer understood or accepted, and new values and meanings have not developed. Such a society produces, in many of its members, psychological states characterized by a sense of futility, lack of purpose, and emotional emptiness and despair. Striving is considered useless, because there is no accepted definition of what is desirable.

Robert K. Merton, in the United States, studied the causes of anomie, or normlessness, finding it severest in persons who do not have acceptable means of achieving their cultural goals. Goals may become so important that, if institutionalized means—*i.e.*, those means acceptable according to the standards of the society—fail, illegitimate means may be used. Greater emphasis on ends rather than means results in a stress that leads to a breakdown in the regulatory structure—*i.e.*, anomie. If, for example, a society impelled its members to acquire wealth, yet offered inadequate means for them to do so, the strain would cause many people to violate norms. The only regulating agencies would be the desire for personal advantage and the fear of punishment. Social behaviour thus becomes unpredictable. Delinquency, crime, and suicide are often reactions to anomie.

Although Durkheim's concept of anomie referred to a condition of relative normlessness of a society or social group, other writers have used it to refer to conditions of individuals. In this psychological usage, anomie means the state of mind of a person who has no standards or sense of continuity or obligation and who has rejected all social bonds. Individuals may feel that community leaders are indifferent to their needs, that society is basically unpredictable and lacking order, and that goals are not being realized. They may have a sense of futility and a conviction that associates are not dependable sources of support.

Anomoean (from Greek *anomoiōs*, "unlike"), any member of a religious group of the 4th century that represented an extreme form of Arianism (*q.v.*), a Christian heresy that held that the essential difference between God and Christ was that God had always existed, while Christ was created by God. Aëtius, the

founder of the Anomoeans, reasoned that the doctrine carried to its logical conclusion must mean that God and Christ could not be alike. Because *agennēsia* ("self-existence") is a part of the essence of God, Christ could not be like God because he lacked this necessary quality. Aëtius' chief convert and the second leader of the movement was Eunomius, after whose death (c. 394) the Anomoeans soon disappeared.

anomy (sociology): *see* anomie.

anorexia nervosa, eating disorder characterized by the refusal of an emaciated individual to maintain a normal body weight. A person with anorexia nervosa typically weighs no more than 85 percent of the expected weight for the person's age, height, and sex, and in some cases much less. In addition, people with anorexia nervosa have a psychological disturbance in their ability to evaluate their weight and body shape. They typically consider their emaciated bodies to be attractive or even a bit too fat, do not want to change their diet, and have an intense fear of gaining weight. In women the weight loss is accompanied by amenorrhea (failure to menstruate). An estimated 5 to 10 percent of people with the disorder die as the result of starvation or medical complications that are caused by low weight and a restricted diet. At least 90 percent of all people diagnosed with anorexia nervosa are women, and most are between 12 and 25 years of age.

The term *anorexia nervosa* was first used in the late 19th century by British physician Sir William Withey Gull, but it was not officially recognized as a disorder until 1980, when its incidence was seen to have increased greatly. Most experts blame the rise in anorexia nervosa on the unrelenting focus in the popular media on young women's appearance, especially the emphasis on thinness as an ideal in affluent industrialized countries. Anorexia nervosa is far more prevalent in the United States, Europe, and industrialized Asia than it is elsewhere in the world.

Anorexia nervosa usually begins in adolescence or early adulthood. Some of the factors that appear to contribute to its development are a negative body image, a lack of awareness of internal feelings (including hunger and emotions), and various control issues that may stem from obsessive tendencies, a sense of lack of control over one's life, or the sense of triumph felt as a result of gaining control over a basic biological need. Other emotional disorders, particularly depression and obsessive-compulsive disorders, often coexist with anorexia nervosa.

Research has not identified a clearly effective treatment for anorexia nervosa. Various forms of psychotherapy are used in an attempt to treat it, and family therapy that includes parents and sometimes siblings appears to be of benefit for adolescents. Hospitalization may be required in cases of extreme weight loss because of its potentially life-threatening nature. The disorder has proved to be difficult to treat either with psychotherapy or with antidepressants or other medications. Studies show that about one-half of those who receive treatment for anorexia nervosa remain below their expected body weight years after treatment, and many of the rest continue to struggle with eating, dieting, and their body image.

anorthite, a feldspar mineral, calcium aluminosilicate ($\text{CaAl}_2\text{Si}_2\text{O}_8$), that occurs as white or grayish, brittle, glassy crystals. Primarily a rock-forming mineral, it is used in the manufacture of glass and ceramics. Anorthite occurs in basic igneous rocks, as at Trentino, Italy; Södermanland, Swed.; Tamil Nadu, India; Miyake, Japan; and Franklin, N.J. For detailed physical properties, *see* feldspar (table).

The feldspar minerals are mixtures of sodium,

potassium, and calcium aluminosilicates; they belong to a ternary system in which any mineral may be classed by its percentage of each of three pure compounds, called end-members: sodium aluminosilicate, potassium aluminosilicate, and calcium aluminosilicate. Anorthite is the calcium-bearing end-member of the system; its symbol is *An*.

Anorthite and the sodium-bearing end-member of the system, albite ($\text{NaAlSi}_3\text{O}_8$), form a solid-solution series in which the two intermingle; thus, in nature there is a continuous chemical variation between the two compounds. Any member of this series is called a plagioclase.

anorthoclase, any member of a continuous series of feldspar minerals related to sanidine (*q.v.*).

anorthosite, type of intrusive igneous rock composed predominantly of calcium-rich plagioclase feldspar. All anorthosites found on Earth consist of coarse crystals, but some samples of the rock taken from the Moon are finely crystalline.

Anorthosite is considerably less abundant than either basalt or granite, but the complexes in which it occurs are, nevertheless, often of immense size. For instance, about 155,000 square km (60,000 square miles) of eastern Canada is underlain by anorthosite, the Saguenay Mass alone accounting for a tenth of this. The Morin Anorthosite in the same area occupies 2,600 square km (1,040 square miles), and the Adirondack Anorthosite is exposed over an area of about 3,900 square km (1,560 square miles). The Bushveld Complex underlies an area of about 50,000 square km (20,000 square miles); and the Great Dyke of Zimbabwe, another layered complex, has been traced for more than 480 km (300 miles).

Although these large masses are generally supposed to provide the best sample of the deep lithosphere (the outer shell of the Earth), they often appear to be floored over most of their outcrop area. They usually occur as laccoliths (low domelike intrusions with a flat base found between sedimentary beds), lopoliths (laccoliths with basin-shaped bases), or sills (tabular intrusions between other rocks). The Canadian anorthosites are thought to be laccolithic, while the Adirondack Anorthosite is considered a floored sheet. The thickness of the Sudbury Lopolith is estimated at 3 km (1.9 miles), that of the Bushveld at 5 km (3 miles). Anorthosite dikes (slablike, steeply inclined intrusions along fissures) are very rare, and effusive equivalents of anorthosite are unknown.

Anouilh, Jean(-Marie-Lucien-Pierre) (b. June 23, 1910, Bordeaux, Fr.—d. Oct. 3, 1987, Lausanne, Switz.), playwright who became one of the strongest personalities of the French theatre and achieved an international reputation. His plays are intensely personal messages; often they express his love of the theatre as well as his grudges against actors, wives, mistresses, critics, academicians, bureaucrats, and others. Anouilh's characteristic

techniques include the play within the play, flashbacks and flash forwards, and the exchange of roles.

The Anouilh family moved to Paris when Jean was a teenager, and it was there that he studied law and worked briefly in advertising. At the age of 18, however, he saw Jean Giraudoux's drama *Siegfried*, in which he discovered a theatrical and poetic language that determined his career. He worked briefly as the secretary to the great actor-director Louis Jouvet.

L'Hermine (performed 1932; *The Ermine*) was Anouilh's first play to be produced, and success came in 1937 with *Le Voyageur sans bagage* (*Traveller Without Luggage*), which was soon followed by *La Sawage* (1938).

Anouilh rejected both Naturalism and Realism in favour of what has been called "theatricalism," the return of poetry and imagination to the stage. Technically he showed a great versatility, from the stylized use of Greek myth, to the rewriting of history, to the *comédie-ballet*, to the modern comedy of character. Although not a systematic ideologist like the Existentialist Jean-Paul Sartre, Anouilh developed his own view of life highlighting the contradictions within human reality, for example, or the ambiguous relationships between good and evil. He called two major collections of his plays *Pièces roses* ("Rose-coloured Plays") and *Pièces noires* ("Black Plays"), in which similar subjects are treated more or less lightly. His dramatic vision of the world poses the question of how far the individual must compromise with truth to obtain happiness. His plays show men or women facing the loss of the privileged world of childhood. Some of his characters accept the inevitable; some, such as the light-headed creatures of *Le Bal des voleurs* (1938; *Thieves' Carnival*), live lies; and others, such as *Antigone* (1944), reject any tampering with ideals.

With *L'Invitation au château* (1947; *Ring Around the Moon*), the mood of Anouilh's plays became more sombre. His aging couples seem to perform a dance of death in *La Valse des toréadors* (1952; *The Waltz of the Toreadors*). *L'Alouette* (1953; *The Lark*) is the spiritual adventure of Joan of Arc, who, like Antigone and Thérèse Tarde (*La Sauvage*), is another of Anouilh's rebels who rejects the world, its order, and its trite happiness. In another historical play, *Becket ou l'honneur de Dieu* (1959; *Becket, or, The Honour of God*), friendship is crushed between spiritual integrity and political power.

In the 1950s Anouilh introduced into his vision of the world the novelty of political ferment: *Pauvre Bitos, ou le Dîner de têtes* (1956; *Poor Bitos*). In the 1960s his plays were considered by many to be dated compared with those of the Absurdist dramatists Eugène Ionesco or Samuel Beckett. *Le Boulanger, la boulangère et le petit mitron* (1968; "The Baker, the Baker's Wife, and the Baker's Boy") was coolly received, but in the following decade other new plays appeared to confirm his place as a master entertainer: *Cher Antoine; ou, l'amour raté* (1969; *Dear Antoine; or, The Love That Failed*), *Les Poissons rouges; ou, Mon père, ce héros* (1970; "The Goldfish; or, My Father, This Hero"), *Ne réveillez pas madame* (1970; "Do Not Awaken the Lady"), *Le Directeur de l'opéra* (1972), *L'Arrestation* (1975; "The Arrest"), *Le Scénario* (1976), *Vive Henry IV* (1977), and *La Culotte* (1978; "The Trousers").

Anouilh also wrote several successful film scenarios and translated from English some works of other playwrights.

Anpu (Egyptian god): see Anubis.

Anqing (China): see An-ch'ing.

Anquetil-Duperron, A(braham)-H(yacinthe) (b. Dec. 7, 1731, Paris—d. Jan. 17, 1805, Paris), scholar and linguist who was gen-

erally credited with supplying the first translation of the Avesta (Zoroastrian scripture) into a modern European language and with awakening interest in the study of Eastern languages and thought.

At the University of Paris, Anquetil mastered Hebrew as his first Eastern language; later, he added Persian and Arabic to his linguistic stock. At the Royal Library in Paris he found some ancient works in Avestan, an Iranian language of the time of the 6th-century-BC religious prophet Zoroaster. The largest remaining group of Zoroastrians, the Parsis, had fled to India to escape Muslim persecution. In search of the ancient Zoroastrian texts, Anquetil traveled to India, where he acquired and translated nearly 200 such manuscripts. He also wrote numerous papers and treatises on Oriental languages, laws, and systems of government.

In 1771 his *Zend-Avesta* appeared. Despite its many discrepancies and inaccuracies, it remains a pioneer work. Among his other works are *Législation orientale* (1778), *Historical and Geographical Research on India* (1786), and *The Dignity of Commerce and the Commercial State* (1789). His *India in Rapport with Europe* appeared in 1798, and his last major work was *Upanishada* (1804; "Secrets Never To Be Revealed").

Ansar, also spelled AL-ANŞĀR (Sudanese faction): see Mahdist.

Ansbach, formerly ANSPACH, city, Bayern Land (state), southern Germany, on the Rezat River, southwest of Nürnberg. It originated around the Benedictine monastery of Onolzbach (founded 748) and was sold to a Franconian branch of the Hohenzollern line (later margraves of Brandenburg-Ansbach-Bayreuth) in 1331. It passed to Prussia in 1791 and to Bavaria in 1806. Queen Caroline, consort of George II of Great Britain, was born there in 1683, and there is a memorial to Kaspar Hauser (a mysterious youth reputed to be the hereditary prince of Baden), who died there in 1833.

Notable buildings in Ansbach include the 12th-century Romanesque Church of St. Gumbertus (which has been restored in the Baroque style) and the palace of the margraves (1713–32), with a fine park. The biennial International Bach Week at Ansbach begins in late July.

A rail and road junction, Ansbach has printing, metal, textile, plastic, cardboard, and leather industries. Pop. (1989 est.) 36,912.

Anschar, SAINT (patron saint of Scandinavia): see Ansgar, Saint.

Anschluss (German: "Union"), political union of Austria with Germany, achieved through annexation by Adolf Hitler in 1938. Mooted in 1919 by Austria, Anschluss with Germany remained a hope (chiefly with Austrian Social Democrats) during 1919–33, after which Hitler's rise to power made it less attractive.

In July 1934 Austrian and German Nazis together attempted a coup but were unsuccessful. An authoritarian right-wing government then took power in Austria and kept perhaps half the population from voicing legitimate dissent; that cleavage prevented concerted resistance to the developments of 1938. In February 1938 Hitler invited the Austrian chancellor Kurt von Schuschnigg to Germany and forced him to agree to give the Austrian Nazis virtually a free hand. Schuschnigg later repudiated the agreement and announced a plebiscite on the Anschluss question. He was bullied into canceling the plebiscite, and he obediently resigned, ordering the Austrian Army not to resist the Germans. President Wilhelm Miklas of Austria refused to appoint

Anouilh, 1953
H. Roger-Viollet

the Austrian Nazi leader Arthur Seyss-Inquart as chancellor. The German Nazi minister Hermann Göring ordered Seyss-Inquart to send a telegram requesting German military aid, but he refused, and the telegram was sent by a German agent in Vienna. On March 12 Germany invaded, and the enthusiasm that followed persuaded Hitler to annex Austria outright on March 13. A controlled plebiscite of April 10 gave a 99.7 percent approval.

Anselm OF BAGGIO: see Alexander II under Alexander (Papacy).

Anselm OF CANTERBURY, SAINT (b. 1033/34, Aosta, Lombardy—d. April 21, 1109, possibly at Canterbury, Kent, Eng., canonized 1163?; feast day April 21), founder of Scholasticism, a philosophical school of thought that dominated the Middle Ages; he was recognized in modern times as the originator of the

St. Anselm (centre), terra-cotta altarpiece by Luca della Robbia; in the Museo Diocesano, Empoli, Italy
Alinari—Art Resource/EB Inc

ontological argument for the existence of God (based on the idea of an absolutely perfect being, the fact of the idea being in itself a demonstration of existence) and the satisfaction theory of the atonement or redemption (based on the feudal theory of making satisfaction or recompense according to the status of a person against whom an offense has been committed, the infinite God being the offended party and man the offender). Incomplete evidence suggests that he was canonized in 1163.

Early life and career. Anselm was born in the Piedmont region of northwestern Italy. His birthplace, Aosta, was a town of strategic importance in Roman imperial and in medieval times, because it stood at the juncture of the Great and Little St. Bernard routes. His mother, Ermenberga, belonged to a noble Burgundian family and possessed considerable property. His father, Gondolfo, was a Lombard nobleman who intended that Anselm would make a career of politics and did not approve of his early decision to enter the monastic life. Anselm received an excellent classical education and was considered one of the better Latinists of his day. His early education impressed on him the need to be precise in his use of words, and his writings became known for their clarity.

In 1057 Anselm left Aosta to enter the Benedictine monastery at Bec (located between Rouen and Lisieux in Normandy, France), because he wanted to study under the monastery's renowned prior, Lanfranc. While on his way to Bec, he learned that Lanfranc was in Rome, so he spent some time at Lyon, Cluny, and Avranches before entering the monastery in 1060. In 1060 or 1061 he took his monastic vows. Because of Anselm's reputation for

great intellectual ability and sincere piety, he was elected prior of the monastery after Lanfranc became abbot of Caen in 1063. In 1078 he became abbot of Bec.

In the previous year (1077), Anselm had written the *Monologium* ("Monologue") at the request of some of his fellow monks. A theological treatise, the *Monologium* was both apologetic and religious in intent. It attempted to demonstrate the existence and attributes of God by an appeal to reason alone rather than by the customary appeal to authorities favoured by earlier medieval thinkers. Moving from an analysis of the inequalities of various aspects of perfection, such as justice, wisdom, and power, Anselm argued for an absolute norm that is everywhere at all times, above both time and space, a norm that can be comprehended by the mind of man. Anselm asserted that that norm is God, the absolute, ultimate, and integrating standard of perfection.

Under Anselm, Bec became a centre of monastic learning and some theological questioning. Lanfranc had been a renowned theologian, but Anselm surpassed him. He continued his efforts to answer satisfactorily questions concerning the nature and existence of God. His *Proslogium* ("Address," or "Allocution"), originally titled *Fides quaerens intellectum* ("Faith Seeking Understanding"), established the ontological argument for the existence of God. In it he argued that even a fool has an idea of a being greater than which no other being can be conceived to exist; that such a being must really exist, for the very idea of such a being implies its existence.

Anselm's ontological argument was challenged by a contemporary monk, Gaunilo of Marmoutier, in the *Liber pro insipiente*, or "Book in Behalf of the Fool Who Says in His Heart There Is No God." Gaunilo denied that an idea of a being includes existence in the objective order and that a direct intuition of God necessarily includes God's existence. Anselm wrote in reply his *Liber apologeticus contra Gaunilonem* ("Book [of] Defense Against Gaunilo"), which was a repetition of the ontological argument of the *Proslogium*.

Appointment as archbishop of Canterbury. William the Conqueror, who had established Norman overlordship of England in 1066, was a benefactor of the monastery at Bec, and lands in both England and Normandy were granted to Bec. Anselm made three visits to England to view these lands. During one of those visits, while Anselm was founding a priory at Chester, William II Rufus, the son and successor of William the Conqueror, named him archbishop of Canterbury (March 1093). The see had been kept vacant since the death of Lanfranc in 1089, during which period the King had confiscated its revenues and pillaged its lands.

Anselm accepted the position somewhat reluctantly but with an intention of reforming the English Church. He refused to be consecrated as archbishop until William restored the lands to Canterbury and acknowledged Urban II as the rightful pope against the antipope Clement III. In fear of death from an illness, William agreed to the conditions, and Anselm was consecrated Dec. 4, 1093. When William recovered, however, he demanded from the new archbishop a sum of money, which Anselm refused to pay lest it look like simony (payment for an ecclesiastical position). In response to Anselm's refusal, William refused to allow Anselm to go to Rome to receive the pallium—a mantle, the symbol of papal approval of his archiepiscopal appointment—from Urban II, lest this be taken as an implied royal recognition of Urban. In claiming that the king had no right to interfere in what was essentially an ecclesiastical matter, Anselm became a major figure in the investiture controversy; i.e., over the question as to whether a secular ruler (e.g., emperor or king)

or the pope had the primary right to invest an ecclesiastical authority, such as a bishop, with the symbols of his office.

The controversy continued for two years. On March 11, 1095, the English bishops, at the Synod of Rockingham, sided with the King against Anselm. When the papal legate brought the pallium from Rome, Anselm refused to accept it from William, since it would then appear that he owed his spiritual and ecclesiastical authority to the king. William permitted Anselm to leave for Rome, but on his departure he seized the lands of Canterbury.

Anselm attended the Council of Bari (Italy) in 1098 and presented his grievances against the King to Urban II. He took an active part in the sessions, defending the doctrine of the *Filioque* ("and from the Son") clause in the Nicene-Constantinopolitan Creed against the Greek Church, which had been in schism with the Western Church since 1054. The *Filioque* clause, added to the Western version of the Creed, indicated that the Holy Spirit proceeded from the Father and Son. The Greek Church rejected the *Filioque* clause as a later addition. The Council also reapproved earlier decrees against investiture of ecclesiastics by lay officials.

The satisfaction theory of redemption. When Anselm left England, he had taken with him an incomplete manuscript of his work *Cur Deus homo?* ("Why Did God Become Man?"). After the Council of Bari, he withdrew to the village of Liberi, near Capua, and completed the manuscript in 1099. This work became the classic treatment of the satisfaction theory of redemption. According to this theory, which is based upon the feudal structure of society, finite man has committed a crime (sin) against infinite God. In feudal society, an offender was required to make recompense, or satisfaction, to the one offended according to that person's status. Thus, a crime against a king would require more satisfaction than a crime against a baron or a serf. According to this way of thinking, finite man, since he could never make satisfaction to the infinite God, could expect only eternal death. The instrument for bringing man back into a right relationship with God, therefore, had to be the God-man (Christ), by whose infinite merits man is purified in an act of cooperative recreation. Anselm rejected the view that man, through his sin, owes a debt to the devil, and placed the essence of redemption in individual union with Christ in the Eucharist (Lord's Supper), to which the sacrament of Baptism (by which a person is incorporated into the church) opens the way.

After completing *Cur Deus homo?* Anselm attended a council at the Lateran (papal palace) in Rome at Easter 1099. One year later, William Rufus died in a hunting accident under suspicious circumstances, and his brother Henry I seized the English throne. In order to gain ecclesiastical support, he sought for and secured the backing of Anselm, who returned to England. Anselm soon broke with the King, however, when Henry insisted on his right to invest ecclesiastics with the spiritual symbols of their office. Three times the King sought an exemption, and each time the Pope refused. During this controversy, Anselm was in exile, from April 1103 to August 1106. At the Synod of Westminster (1107), the dispute was settled. The King renounced investiture of bishops and abbots with the ring and crosier (staff), the symbols of their office. He demanded, however, that they do homage to him prior to consecration. The Westminster Agreement was a model for the Concordat of Worms (1122), which settled for a time the lay-investiture controversy in the Holy Roman Empire.

Anselm spent the last two years of his life in peace. In 1163, with new canons requiring approvals for canonization (official recognition of persons as saints), Archbishop Thomas

Becket of Canterbury (1118?–1170) referred Anselm's cause to Rome. Anselm was probably canonized at this time, for the Canterbury records for 1170 make frequent mention of the pilgrimages to his new shrine in the cathedral. For several centuries he was venerated locally. Clement XI (pope from 1700 to 1721) declared Anselm a doctor (teacher) of the church in 1720.

Anselm OF LAON, French ANSELME DE LAON (b. first half of the 11th century, Laon, Archbishopric of Laon—d. July 15, 1117, Laon), theologian who became eminent in early Scholasticism.

Anselm apparently studied at Bec, Fr., under St. Anselm of Canterbury. In the final quarter of the 11th century, he taught with distinction at Paris, where with William of Champeaux he supported realism. About 1100 he returned to Laon, where his theological and exegetical school became famous. Peter Abelard attended Anselm's school (c. 1114), and John of Salisbury referred to Anselm and Anselm's brother Rudolph as "those most brilliant lights of the Gauls."

Anselm was influenced by the Platonic and the Neoplatonic ideas transmitted by Bishop St. Augustine of Hippo. Anselm's principal work was *Interlinear Glosses*, a commentary on the entire Vulgate Bible; it became a leading medieval authority. Some of his scriptural commentaries were ascribed to other writers, notably St. Anselm. His known works were published by J.-P. Migne in *Patrologia Latina* (vol. 162).

Anselm OF LUCCA: see Alexander II under Alexander (Papacy).

Anselm OF SAINT MARY, also called FATHER ANSELM, French ANSELME DE SAINTE-MARIE, or PÈRE ANSELME, original name PIERRE DE GUIBOURS (b. 1625, Paris—d. Jan. 17, 1694, Paris), genealogist and friar whose history of the French royal family and nobility

is a valuable source of detailed and unusual information.

Anselm entered the order of the Discalced Hermits of St. Augustine in 1644 and, remaining in their monastery (Couvent des Petits Pères), devoted his entire life to genealogical studies. Among his early works are *Le Palais de l'honneur* (1663–1668; "The Palace of Honour"), concerning the genealogy of the houses of Lorraine and Savoy; *Le Palais de la gloire* (1664; "The Palace of Glory"), dealing with the genealogy of various illustrious French and European families; and *La Science héraldique* (1675; "The Science of Heraldry").

His most important work is the *Histoire généalogique et chronologique de la maison royale de France, des pairs, des grands officiers de la couronne, et de la maison du roy et des anciens barons du royaume* (2 vol., 1674; "Genealogical and Chronological History of the Royal House of France, the Peers, the Grand Officers of the Crown, and of the Royal House and the Ancient Barons of the Realm"). After his death this history of French nobility was continued by Honoré Caille, seigneur du Fourny, who had encouraged its publication, and by two other friars at the monastery. The third and most complete edition is that of 1726–33. A valuable source, it contains in its notes exact references to many original documents.

Anselme, Nicolas (French actor): see Baptiste.

Anser, bird genus of the family Anatidae (order Anseriformes). For a general discussion of the genus, see goose; for *A. albifrons*, see white-fronted goose; for *A. anser*, see greylag; for *A. caerulescens*, see snow goose.

Articles are alphabetized word by word, not letter by letter

anseriform, any member of the bird order Anseriformes, which contains the waterfowl, or wildfowl, family Anatidae (ducks, geese, and swans) and the screamers (family Anhimidae).

A brief treatment of anseriforms follows. For full treatment, see MACROPAEDIA: Birds.

Waterfowl are typically stocky birds with medium to long necks. The bill is generally of medium length, somewhat flattened, and often has a hooked nail on the tip. There is no characteristic wing shape among the waterfowl, but all of these birds are capable of flight, and many undertake extensive migrations. The screamers are long-legged, and their very large toes are webbed only at the base. Their bill is more chickenlike than ducklike and has a pronounced downward hook.

The anseriforms, along with the ratites, curassows, and tinamous, possess an intromittent male organ. While this is not homologous to the mammalian penis, it serves the same reproductive function. Its presence, and the concomitant ability to mate while swimming, undoubtedly helped the anseriforms as they diversified into their aquatic niches.

Several species of waterfowl have been domesticated. The mallard (*Anas platyrhynchos*) has been domesticated for at least 2,000 years. The muscovy duck (*Cairina moschata*) was domesticated in pre-Columbian South America. The greylag goose (*Anser anser*) and swan goose (*A. cygnoides*) are the basis of the several varieties of domestic geese. Wild waterfowl were important to early man as a source of meat, feathers, fat, and down. In some parts of the modern world, sport hunting of waterfowl is a major leisure activity.

There are three main feeding styles within the waterfowl: dabbling, diving, and grazing. Dabbling ducks feed on or just below the surface and are known for upending to reach food (mostly vegetation) on the bottom of shallow waters. Among the diving waterfowl

the freshwater forms generally inhabit fairly shallow waters and feed mostly on the seeds, leaves, and roots of aquatic plants. The marine ducks inhabit deeper sea waters and live on fish and invertebrates.

Waterfowl are typically social birds and have a well-developed set of formal displays and group cohesion signals; for instance, in many species a head-shaking or chin-lifting display is used to coordinate group takeoff. Swans and geese use vocalizations to maintain contact while in flight. Preening and maintenance of plumage is a major individual activity.

Most waterfowl have highly developed, innate pair-forming and bonding displays which differ from species to species. Among the ducks, which generally take a new mate each season, various bows and poses such as the "head-up-tail-up" display exhibit plumage markings that are otherwise not usually seen. In species that mate for life, such as the swans and geese, displays serve to reinforce the pair bond. The "triumph ceremony" of geese, for example, in which both birds call and wave their heads, is commonly performed after the male has driven off a rival.

Almost all waterfowl breed in water, which provides safety and isolation. Territoriality plays a part in mating. Nest site selection and nest building are usually done by the female who pulls together any vegetation within reach. The eggs are usually laid one per day, in the morning. The shells may be white, green, or brown and clutches of the various species average from 3 to 12 eggs. The incubation period ranges from 22 to 39 days and incubation is almost always the job of the female. Shortly after hatching the young waterfowl imprint on their mother. Imprinting is an instinctive response to attach to and follow the nearest large moving object. The down-covered waterfowl follow the mother from the nest within 24 to 48 hours and are soon swimming and feeding. Young ducks may fledge as early as five weeks and are then on their own. Larger species, however, may not fledge for up to five months and geese and swans complete their first migration in the company of the parents. All of these birds are fairly long-lived; in captivity ducks may live 20 years, geese and swans for more than 30.

Migration is a characteristic of many anseriform species, increasing the ecological flexibility of waterfowl. However, as their habitats are being destroyed, many species are facing extreme population pressures.

Ansermet, Ernest (b. Nov. 11, 1883, Vevey, Switz.—d. Feb. 20, 1969, Geneva), conductor known for his authoritative interpretations of the works of Stravinsky and other 20th-century composers and for his keen intellectual approach to problems of contemporary musical aesthetics. He studied at Lausanne and from 1906 to 1910 taught mathematics there. Later he studied composition under the Swiss-born composer Ernest Bloch and conducted under two outstanding figures, Felix Mottl and Arthur Nikisch. About 1914 he met Stravinsky and in 1915 he became conductor of Diaghilev's Ballets Russes. In 1918 he formed the renowned Orchestre de la Suisse Romande, which he led until 1967. He frequently toured Europe and the U.S. and introduced many works by contemporary composers. Late in life he turned against 12-tone music (e.g., in his book *The Fundamentals of Music in the Human Consciousness*, 1961), although he continued to espouse other contemporary music.

His own works include a symphonic poem, settings of poems by Baudelaire, and the orchestration of Debussy's *Épigraphes antiques*.

Ansett Transport Industries Limited, Australian conglomerate founded in 1936 (as

Anselm of Saint Mary, engraving by François Huret
J.E. Bullock

Ansett Airways Proprietary Ltd.) by Reginald Ansett. Head offices are in Melbourne.

Ansett (Sir Reginald since 1969) began in 1931 with a motorcar passenger service in the Western District of the state of Victoria. In 1936 he founded the airline company for service between Melbourne and Hamilton. After World War II the company began new interstate services and manufacturing and in 1946 changed its name to Ansett Transport Industries Limited. By 1951 the company had extended its activities into hotels and was operating some 200 motor coaches. In 1957 it purchased Australia's largest privately owned airline, Australian National Airways (renamed Ansett Airlines of Australia), and later acquired other regional airlines in Australia and New Guinea. The company secured a license for a television station in Melbourne in 1963 and another one in Brisbane in 1964. Further diversification extended into motels, resorts, freight services, industrial equipment manufacturing, automotive sales, aircraft sales, etc. In 1979 Rupert Murdoch, the newspaper baron, gained control through majority interest in Ansett.

Ansgar, SAINT, Ansgar also spelled ANSKAR, or ANSCHAR (b. probably 801, near Corbie, Austrasia [France]—d. Feb. 3, 865, Bremen, Saxony [Germany]; canonized 865; feast day February 3), missionary of medieval Europe, first archbishop of Hamburg, and the patron saint of Scandinavia.

Of noble birth, Ansgar entered the Benedictine abbey of Corbie in Picardy, where he was educated. After 823 he taught in the monastic school at Corvey ("New Corbie"), Westphalia, where he also began his pastoral work. When Harald, an exiled Danish king, appealed to the Carolingian emperor Louis I the Pious for support, Louis dispatched Ansgar to accompany and assist the king in evangelizing Denmark. Ansgar in 826 began short-lived missionary work in Schleswig. Harald's downfall in 827 and the death of his assistant, Autbert, were blows to the mission, and in 829 Ansgar returned to the Franks. With the help of Witmar, a monk from Corvey, Ansgar began his evangelization of Sweden. The first to preach the gospel in Sweden, he was cordially received by King Björn.

Louis recalled Ansgar in 831, making him abbot of Corvey and bishop of the newly established diocese of Hamburg. Consecrated in 832, he initiated a mission to all the Scandinavian peoples and went to Rome, where Pope Gregory IV made him archbishop and papal legate to the Scandinavians and Slavs, thereby earning him the title of "the Apostle of the North." At Hamburg, Ansgar founded a monastery and a school, and in 834 Louis endowed him with Turholt Abbey, to be used as the centre of his activities.

When Denmark had become united under King Haarik (Horec) I, he allowed the revival of Ansgar's work in Schleswig. Ansgar lost Turholt after Louis I's death (840); and in 845 Northmen destroyed Hamburg, and the Swedish missions were extinguished by the expulsion of Bishop Gautbert. Returning to paganism, Sweden and Denmark rejected Christianity.

In 847 Louis the German, king of the East Franks, made Ansgar bishop of Bremen, from where he revived and redirected his northern evangelization. He dispatched a missionary to Sweden in 851 and converted the succeeding Danish king Haarik II. He then went to Sweden (853–854), where the king (himself destined for conversion) allowed the Christian missionaries to preach. Ansgar succeeded in thwarting a pagan rebellion before returning to Bremen. He was canonized shortly after his death by Pope St. Nicholas I the Great.

BIBLIOGRAPHY. Charles H. Robinson (trans.), *Anskar: The Apostle of the North, 801–865* (1921), is a biography by Ansgar's successor as bishop of Bremen, St. Rembergt, and is important as a historical document and portrait.

Anshan, also spelled ANZAN, city and territory of ancient Elam, north of modern Shirāz, southwestern Iran. The city's ruins, covering 350 acres, have yielded major archaeological finds, including examples of early Elamite writing. Anshan came to prominence about 2350 BC as an enemy of the Mesopotamian dynasty of Akkad. Its greatest period, however, was during the 13th and 12th centuries BC, when, as "kings of Anshan and Susa," Elamite rulers periodically raided Babylonian cities. About 675 the country apparently came to be controlled by Achaemenian Persians, who bore the title "kings of Anshan" down to the accession of Darius I (522 BC).

Anshar and Kishar, in Mesopotamian mythology, the male and female principles, the twin horizons of sky and earth. Their parents were either Apsu (the watery deep beneath the earth) and Tiamat (the personification of salt water) or Lahmu and Lahamu, the first set of twins born to Apsu and Tiamat. Anshar and Kishar, in turn, were the parents of Anu (An), the supreme heaven god. *See also* Anu.

Anskar, SAINT: *see* Ansgar, Saint.

Ansky, S., Ansky also spelled AN-SKI, pseudonym of SOLOMON ZANVEL RAPPOPORT (b. 1863, Vitebsk, Russia [now in Belarus]—d. Nov. 8, 1920, Warsaw, Poland), Russian Jewish writer and folklorist best known for his play *The Dybbuk*.

Ansky was educated in a Hasidic environment and as a young man was attracted to the Jewish Enlightenment (Haskala) and to the populist doctrines of the Narodniki, a group of socialist revolutionaries. For a time he worked among the peasants and contributed articles to the Narodnik journal. His first novel, written in Yiddish, was published in 1884.

Compelled to leave Russia in 1892, he settled in Paris. Working as a factory hand, Ansky studied French folklore and socialist doctrine and became secretary to the revolutionary émigré Pyotr Lavrov. He also wrote articles and popular poems, many of them for the Jewish Workers' Party, the Bund. In 1905 he was permitted to return to St. Petersburg. He joined the Socialist Revolutionary Party, ideological heir of the Narodniki, and continued to write articles, folktales, and short stories on Jewish life.

In 1911 Ansky organized a large-scale ethnographic expedition to gather Jewish folklore, songs, melodies, manuscripts, and books. His fieldwork was interrupted by the outbreak of World War I, during which he did relief work and wrote about the destruction of the Jewish communities in Poland, Galicia, and Bukovina. Also during this period he produced his most famous work, the classic Yiddish drama *Der Dibek* (written 1914, first performed 1920; *The Dybbuk*). The play, which drew on Jewish mystical folklore, was widely translated and performed, most notably in the celebrated Moscow production of the Hebrew company Habima. It was also set to music and was filmed in Yiddish and Hebrew.

After the Russian Revolution Ansky was elected to the All-Russia Constituent Assembly, but in 1918 he left for Vilna. The following year he settled near Warsaw and devoted himself to preparing his collected works and to organizing a Jewish ethnographic society. His Yiddish works, in 15 volumes, were published between 1920 and 1925.

Anson, Cap, byname of ADRIAN CONSTANTINE ANSON (b. April 11/17, 1851, Marshalltown, Iowa, U.S.—d. April 14, 1922, Chicago, Ill.), American professional baseball player and manager, known later as Pop, who played

professionally for 27 years and was still in his team's regular lineup at the age of 46.

Anson played in the National Association, the first professional baseball league, with the Forest City team of Rockford, Ill., in 1871 and with the Philadelphia Athletics (1872–75). He is believed to have batted .352 during those five years. In 1876, when the Chicago National Association team switched to the newly formed National League, Anson joined this club, and in 1879 he became its manager. He retired as a player and resigned as Chicago manager after the 1897 season and then was nonplaying manager of the New York team in the National League in 1898.

Anson, who played first base for most of his career, was credited with batting championships in 1879, 1881, 1887, and 1888. He hit .399 in 1881 and is thought to have batted over .400 in 1879 and 1887. His total of hits in the National League is given as 2,995 or 3,081 (authorities differ); his National League career batting average is .329 or .339.

As a manager Anson led Chicago to five National League championships. He was elected to the Baseball Hall of Fame in 1939.

Anson, George Anson, Baron (b. April 23, 1697, Shugborough, Staffordshire, Eng.—d. June 6, 1762, Moor Park, Hertfordshire), British admiral whose four-year voyage around the world is one of the great tales of naval heroism. The reforms he instituted as a naval administrator increased the efficiency of the British fleet and contributed to its success in the Seven Years' War (1756–63) against France.

Anson entered the Royal Navy in 1712 and became a captain 11 years later. In September 1740 Commodore Anson set off across the Atlantic with six poorly manned, ill-equipped vessels to capture Spanish treasure ships in

Baron Anson, detail of an oil painting by an unknown artist, c. 1745–46; in the National Maritime Museum, Greenwich, Eng.

By courtesy of the National Maritime Museum, Greenwich, Eng.

the Pacific. He lost three ships rounding Cape Horn but went on to raid Spanish mining settlements on the coast of Chile. Although he and his crew suffered incredible hardships while crossing the Pacific in their one remaining ship, the *Centurion*, Anson managed to capture a Spanish treasure galleon near the Philippines. He sold this prize for £400,000 in Canton, China, the *Centurion* being the first British warship to enter Chinese waters. By the time he reached England in June 1744, more than half the original crew of nearly 2,000 men had died, chiefly of scurvy.

Because of the support of the Duke of Newcastle, Anson was first lord of the Admiralty from 1751 to 1756. Although sacked by William Pitt, Anson returned as first lord from 1757 to 1762. His reforms included a reorganization of the fleet, a revision of the articles of war, and the creation of a permanent marine corps.

BIBLIOGRAPHY. S.W.C. Pack, *Admiral Lord Anson* (1960), is a biography. L.A. Wilcox, *Anson's Voyage* (1969), adapts Anson's original account.

Ansongo, town, southeastern Mali, West Africa, on the Niger River. It is a mining (antimony) and agricultural (grains, livestock) marketing centre. Prospecting for uranium began in the late 1970s. The Niger is navigable for about 1,000 mi (1,600 km) above Ansongo. Directly to the east is the Ansongo-Ménaka animal reserve, which covers an area of more than 4,300,000 ac (1,750,000 ha). Pop. (1987) 7,188.

Ansonia, city, coextensive with the town (township) Ansonia of New Haven county, southwestern Connecticut, U.S., on the Naugatuck River. From 1651 a part of the township of Derby, it was incorporated as a separate township in 1889 and chartered as a city in 1893. Its separate identity was established in 1843 when Anson Greene Phelps of New York City refused to pay an exorbitant price for land in Derby and established his copper and brass mills at the settlement that took his given name. Heavy machinery was manufactured there as early as 1848. Ansonia and the neighbouring cities of Derby and Shelton form one of the important groups of industrial communities of the state. Pop. (2000) 18,554.

Anspach (Germany): see Ansbach.

Anstey, Christopher (b. Oct. 31, 1724, Brinkley, Cambridgeshire, Eng.—d. Aug. 3, 1805, Bath, Somerset), poet whose epistolary novel in verse, *The New Bath Guide*, went through more than 30 editions between 1766 and 1830. After an education at Eton and at King's College, Cambridge, Anstey in 1754 inherited an independent income; and in 1770

Anstey, detail of an engraving by F. Engleheart after a drawing by J. Thurston

Mary Evans Picture Library, London

he settled permanently at Bath, fashionable spa of the 18th century. *The New Bath Guide; or, Memoirs of the B—R—D Family* (1766) is a satire on various aspects of Bath life.

Much of the poem's charm arises from Anstey's mastery of versification, but the element of parody, together with the simple caricature and occasional accurate delineation of scenes well-known to 18th-century readers, helps to explain the poem's popularity.

ant, any member of the approximately 8,000 species of the insect family Formicidae (order Hymenoptera). Ants occur worldwide but are especially common in hot climates. All ants are social in habit; *i.e.*, they live together in organized colonies, and they range in size from 2 to about 25 millimetres (about 0.08 to 1 inch). Their colour is usually yellow, brown, red, or black. A few genera (*e.g.*, *Pheidole* of North America) have a metallic lustre.

Typically, an ant has a large head and a slender, oval abdomen joined to the thorax, or midsection, by a small waist. The antennae are elbowed. The mouth has two sets of jaws: the outer pair is used for carrying objects such as food and for digging, and the inner pair is used for chewing. Some species have a powerful sting at the tip of the abdomen.

There are generally three castes, or classes: queens, males, and workers. Some species live

(Top to bottom) The carpenter ant (*Camponotus*) may be a household pest; when some of the seeds stored by harvester ants (*Pogonomyrmex*) germinate, the young plants are carried from the nest and may grow around the nest opening; army ants (*Eciton*) do not build nests but form a clustered mass with their bodies; driver ants (*Dorylus*), like army ants, have enormous wingless queens, who lay up to about 25,000 eggs at a time

(Top two) Grace Thompson from The National Audubon Society Collection—Photo Researchers/EB Inc., (bottom two) E S Ross

in the nests of other species as parasites; *i.e.*, the larvae are given food and nourishment by the host workers. *Wheeleriella santischii* is a parasite in the nests of *Monomorium salomonis*, the most common ant of northern Africa.

Most ants live in nests, which may be located in the ground or under a rock or built aboveground and made of twigs, sand, or gravel. Carpenter ants (*Camponotus*)—large, black ants common in North America—live in old logs and timbers. Some species live in trees or in the hollow stems of weeds. Tailor, or weaver, ants, found in the tropics of Africa (*e.g.*, *Tetramorium*), make nests of leaves and similar materials held together with silk secreted by the larvae. *Dolichoderus*, a South American genus, glues together bits of animal feces for its nest. The widely distributed pharaoh ant (*Monomorium pharaonis*), a small yellowish insect living in houses, builds its nest outdoors only in warm climates. Army ants, of the subfamily Dorylinae, are nomadic and notorious for the destruction of plant and animal life in their path. The army ants of tropical America (*Eciton*), for example, travel in columns, eating insects and other invertebrates along the way. Periodically the colony rests for several days while the queen lays her eggs. As the colony travels, the growing larvae are carried along. Habits of the African driver ant (*Dorylus*) are similar. The fire ant (*Solenopsis saevissima*), introduced into Alabama from South America, had spread throughout the southern United States by the mid-1970s. It inflicts a painful sting and is considered a pest because it builds large mounds as nests. Effective, ecologically acceptable methods to control it are being sought.

The life cycle of the ant has four stages—egg, larva, pupa, and adult—and spans a period of 8 to 10 weeks. The queen spends her life laying eggs. The workers are females and do the work of the nest; the larger ones, the soldiers, defend the colony. At certain times of the year, many species produce winged males and queens. They fly into the air, where they mate. The male dies soon afterward, and the fertilized queen establishes a new nest.

The food of ants consists of both plant and animal substances. Certain species, including those of the genus *Formica*, often eat the eggs and larvae of other ants or those of their own species; other species eat the liquid secretions of plants. The honey ants (*Camponotinae*, *Dolichoderinae*) eat the so-called honeydew, a by-product of digestion secreted by certain aphids. The ant usually obtains the liquid by gently stroking the aphid's abdomen with its antennae. Some genera (*Leptothorax*) eat the honeydew that has fallen onto the surface of a leaf. The so-called Argentine ant (*Iridomyrmex humilis*) and the fire ant also eat honeydew. Harvester ants (*Messor*, *Pogonomyrmex*) store grass, seeds, or berries in the nest; whereas ants of the genus *Trachymyrmex* of South America eat only fungi, which they cultivate in their nests. The Tes leaf-cutting ant (*Atta texana*) is a pest that often strips the leaves from plants to provide nourishment for its fungus beds.

The social behaviour of the ants, along with that of the honeybees, is the most complex in the insect world. Slave-making ants, which include many species, have a variety of methods for "enslaving" the ants of other species. The queen *Bothriomyrmex decapitans* of Africa, for example, allows herself to be dragged by *Tapinoma* ants into their nest. She then bites off the head of the *Tapinoma* queen and begins laying her own eggs, which are cared for by the "enslaved" *Tapinoma* workers.

ant bear, common name sometimes used for the giant anteater and for the aardvark. See anteater; aardvark.

ant cow (insect): see aphid.

anta, plural **ANTAS**, or **ANTAF**, in architecture, slightly projecting column at the end of a wall, produced by either a thickening of the wall or attachment of a separate strip. The former type, commonly flanking porches of Greek and Roman temples, is a masonry vestige of

Columns in *antis*

the wooden structural posts used to reinforce the brick walls of such early antique temples as the Heraeum of Olympia (c. 600 BC).

The bases and capitals of these antas were not required to conform to the style, or order, of the temple column. The attached strip anta is commonly found in Renaissance and post-Renaissance styles of architecture influenced by classical antiquity. As a decorative feature, the anta is considered to be the forerunner of the pilaster (*q.v.*).

Columns set in the space between antas, such as those in the temple of Ramses III at Madinat Habu, Egypt, are termed "in *antis*."

antacid, also spelled **ANTIACID**, any substance, such as sodium bicarbonate, magnesium hydroxide, or aluminum hydroxide, used to counteract or neutralize gastric acids and relieve the discomfort caused by gastric acidity. Indigestion, gastritis, and several forms of peptic ulcers are alleviated by the use of antacids.

Numerous nonprescription liquid antacids reduce the gastric acidity of indigestion or gastritis for up to three hours after a single dose. Of the many liquid antacids available, those consisting of either magnesium or aluminum alkalizing agents are preferable to antacids containing calcium salts, which have been shown to lead to a secondary increase in gastric acidity. Antacids should be taken when gastric acidity is most likely to be increasing, namely, between one and three hours after each meal and at bedtime. Although they are more convenient, antacid tablets are not nearly so effective as liquid forms. The usual dose of concentrated antacids is one tablespoon and of regular antacids twice that amount. Because magnesium-containing antacids tend to have a laxative effect if used regularly and aluminum-containing antacids tend to constipate, many patients prefer to alternate doses of the two types.

In the treatment of ulcers, acid secretion can be reduced by several agents that block the action of endogenous hormones on the acid-secreting parietal cells of the stomach. Histamine receptor antagonists such as famotidine, ranitidine (Zantac™), and cimetidine (Tagamet™) block histamine receptors on the parietal cells and are effective for about 12 hours. These drugs reduce 24-hour acid secretion by 50 to 75 percent. The most potent acid-inhibitory drugs are the proton pump inhibitors such as omeprazole, lansoprazole, and rabeprazole that block the final pathway of acid secretion and are effective for 15 to 17 hours. Proton pump inhibitors can reduce acid secretion by 90 percent. Histamine recep-

tor antagonists and proton pump inhibitors, when given in conjunction with medication to eradicate *Helicobacter pylori*, are highly successful in healing duodenal ulcers.

A group of drugs known as anticholinergics, which block the receptor for the neurotransmitter acetylcholine, were used for years to delay emptying of the stomach. By doing so, they diminished acid secretion and reduced the frequency and severity of ulcer pain. However, because they only reduce acid secretion by 35 percent and have adverse effects in individuals who have a tendency to develop glaucoma, are markedly debilitated, have an enlargement of the prostate gland, or have difficulty urinating, they are no longer used for treating peptic ulcers.

Antae, also spelled **ANTES**, federation of eastern Slavic nomadic tribes known by the 3rd century AD, dwelling in southern Russia between the Dnepr and Dnestr rivers. A powerful people with highly developed agriculture, handicrafts, and ironwork, the Antae fought the Goths, who were fleeing westward from the Huns in the 4th century. In the early 6th century they joined in Slavic raids against the Byzantine Empire but were nearly annihilated by the Avars, who passed through their lands c. 560. Information about the Antae was recorded by the Gothic historian Jordanes (6th century) and Byzantine historians, including Procopius of Caesarea (6th century).

Antaeus, in Greek mythology, a giant of Libya, the son of the sea god Poseidon and the Earth goddess Gaea. He compelled all strangers who were passing through the country to wrestle with him. Whenever Antaeus touched the Earth (his mother), his strength was renewed, so that even if thrown to the ground, he was invincible. Heracles, in combat with him, discovered the source of his strength and, lifting him up from Earth, crushed him to death.

antagonism, in chemotherapy, any action by which one drug opposes, resists, or counteracts the effects of another. Antagonism may result from changes in the distribution, biotransformation, or excretion of the drugs or may occur because the two drugs act at the same specific cell component (receptor antagonism). A drug that combines with receptors and initiates action has both affinity (*i.e.*, the drug is localized at the receptor) and intrinsic activity (efficacy); such drugs are called agonists.

Sulfonamides, for example, are agonists; they act by preventing the incorporation by certain bacteria of a substance (p-aminobenzoic acid, PABA) necessary for their growth. Substances closely related to PABA (*e.g.*, procaine) have an action similar to it and counteract (*i.e.*, antagonize) sulfonamide action.

In some instances, drug antagonists are deliberately combined, as when digitalis, a stimulant, and quinidine, a depressant, are used to treat congestive heart failure (physiological antagonism). In other instances, antagonism is not advantageous, as when aspirin and probenecid are used to treat gout; either is effective alone, but the action of probenecid is prevented by aspirin when the two are used together.

Antaimoro, also spelled **ANTIMORONA**, a Malagasy people living on and near the southeastern coast of Madagascar. Numbering about 350,000 in the late 20th century, the Antaimoro ("People of the Coast") speak one of the Malagasy languages, a group of closely related Western Austronesian languages. Traditionally the Antaimoro were ruled by five families of Arabic origin who probably came to Madagascar at different times during the 16th century. Several Antaimoro clans claim Indian origins, while others consider themselves indigenous. After the final French conquest of the island in 1895, Antaimoro

political organization was brought into the colonial structure.

The Antaimoro live in dense concentration along river valleys, their villages often adjoining one another and running up and over the tops of the rolling hills characteristic of their land. Others live in a narrow band of coastal swamp and are renowned fishermen. Antaimoro are known for their large canoes rigged with square sails. Women fish in streams or from shore, while men go to open waters. Antaimoro grow rice and other crops in the rich alluvial soils and keep cattle in areas away from the coast. In the past they refined salt for use in trade, and their *ombiasi* (diviner-healers) were celebrated healers, legal arbitrators, and purveyors of amulets and magical medicines. The Antaimoro are among a small minority of Malagasy people who actively practice Islam, although in a form heavily influenced by traditional beliefs. For many years Antaimoro were the only indigenous literate recorders of local history and culture, although the Arabic texts left by early Antaimoro authors have yet to be examined systematically.

Antakya (Turkey): see Antioch.

Antalya, Ancient Greek **ATTALIA**, city and Mediterranean port, southwestern Turkey, on the Gulf of Antalya. Attalia was founded as a seaport in the 2nd century BC by Attalus II, a king of Pergamum. It was bequeathed to the Romans by his successor, Attalus III. St. Paul and St. Barnabas embarked from the seaport on their evangelical mission to Antioch. The

The Yivli Minare (centre) at Antalya, Tur.
Peter Fraenkel—Ostman Agency

"Hadrian Gate," a marble portal of three identical arches, was built to commemorate a visit by Hadrian in AD 130.

During the Middle Ages the city was a Byzantine stronghold and an important embarkation point for troops going to Palestine during the Crusades. It was captured by the Turkish Seljuq ruler Kay-Khusraw in 1207 and soon became the most important town and port of the region. Although it was first occupied by the Ottoman sultan Bayezid I in 1391, its incorporation into the Ottoman Empire was delayed until the late 15th century because of the disruption caused by the invasion of Timur (Tamerlane). In the tripartite agreement of 1917 for the postwar division of the Ottoman Empire among Italy, France, and the United Kingdom, Italy claimed Antalya and its hinterland. Italian troops occupied the district in 1919 but were driven out in July 1921 by Turkish nationalist forces.

With a subtropical warm climate and an abundance of ancient sites nearby, Antalya is the chief tourist resort on the Turkish Riviera. The old town, surrounded by fortified walls restored during Roman, Byzantine, and Seljuq

periods, occupies the summit of a low cliff overlooking the harbour. Notable monuments in the town include an ancient tower, probably once used as a lighthouse, and a Seljuq religious college and mosque dating from 1250. Yivli Minare, a former Byzantine church converted into a Seljuq mosque, now houses the local archaeological museum. Pop. (1997) 512,086.

Antanala (people): see Tanala.

Antananarivo, formerly TANANARIVE, town and national capital of Madagascar, central Madagascar island. It was founded in the 17th century and was the capital of the Hova chiefs. It stands on a high hill. Avenues and flights of steps lead up to a rocky ridge (4,694 feet [1,431 m]) on which stands the Royal Estate, with towered palaces built by the Imerina kings who captured the town in 1794 and ruled until the end of the 19th century. Below are banks and administrative buildings and lower still the commercial quarter. Public buildings include the French Residency and the Anglican and Roman Catholic cathedrals; and there are research institutes, an observatory, and the Bibliothèque Nationale. The University of Madagascar was founded there in 1961. Industries include tobacco and food processing and the manufacture of leather goods and clothing. Air transport is widely used, and the international airport at Ivato is 11 miles (17 km) north of the city. A railway connects the capital with Toamasina, the island's chief port, to the east, as well as with Antsirabe to the south and Lake Alaotra to the north. Pop. (1993) 1,103,304.

Antandroy, also called ANTAMPATRANA, a Malagasy people living in southernmost Madagascar. Numbering about 500,000 in the late 20th century, the Antandroy ("People of the Thorn Bush") speak one of the Malagasy languages, a group of closely related Western Austronesian languages; Antandroy chiefs claim Indian origins. The Antandroy maintained their independence from interior or western Malagasy kingdoms (e.g., Merina and Sakalava), and at the time of the French conquest in 1895 they were divided among five small states that observed the three-tiered social stratification common to Madagascar. The French quickly dissolved all kingdoms and incorporated the Antandroy into their colony. The Antandroy are a pastoral people who tend their cattle herds in the arid, semidesert environment of their native Tulear province. Coastal Antandroy are fishermen. They also grow some crops, including cassava, yams, rice, millet, and corn (maize). Many Antandroy have become migrant labourers in the urban centres of Madagascar, returning to their homeland once they have acquired the funds to purchase a cattle herd of their own.

'**Antar, Romance of**, tales of chivalry centred on the black Arab desert poet and warrior 'Antarah ibn Shaddād, one of the poets of the celebrated pre-Islamic collection *Al-Mu'allaqāt*. It was composed anonymously between the 8th and the 12th century, though the *Romance* itself credits the 9th-century philologist al-Aṣma'ī with its authorship. Written in rhymed prose (*saḥī*) interspersed with 10,000 poetic verses, it is commonly divided into 32 books, each leaving the conclusion of a tale in suspense. The *Romance* relates the fabulous childhood of 'Antar, son of an Arab king by a black slave girl, hence regarded as a bastard by his people, and the adventures he undertakes to attain the hand of his cousin 'Ablah in marriage. These take him beyond Arabia and his own time period to Iraq, Iran, Syria, Spain, North Africa, Egypt, Constantinople, Rome, and the Sudan; they bring him in contact with a Byzantine emperor and with Frankish, Spanish, and Roman kings. Though childless by 'Ablah, 'Antar fathers several children, including two crusaders, Ghadanfar (by

the sister of the king of Rome) and Jufrān (by a Frankish princess).

The *Romance of 'Antar* evolved out of a Bedouin tradition that stressed nobility of character and desert chivalry and of which 'Antar was made the epitome. With the advent of Islām, it assumed a new outlook that reinterpreted 'Antar as a precursor of the new religion. A strong Persian hand in the later authorship of the *Romance*—demonstrated by the detailed knowledge of Persian history and court life—then shows 'Antar in Iran. The *Romance* finally incorporated European elements encountered among the crusaders.

Antarctic Archipelago (Antarctica): see Palmer Archipelago.

Antarctic Circle, parallel, or line of latitude around the Earth, at 66°30' S. Because the Earth's axis is inclined about 23½° from the vertical, this parallel marks the northern limit of the area within which, for one day or more each year, at the summer and winter solstices, the Sun does not set (about December 22) or rise (about June 21). The length of continuous day or night increases southward from one day at the Antarctic Circle to six months at the South Pole. The South Pole is located on the central ice-covered plateau of the large continental mass, the Antarctic, which almost fills the area within the Antarctic Circle. On any date, the length of day and night at the Antarctic Circle is the converse of those at the Arctic Circle. The Antarctic Circle, which separates the South Frigid Zone from the South Temperate Zone, was first crossed by Captain James Cook on Jan. 17, 1773.

Antarctic Circumpolar Current, also called WEST WIND DRIFT, surface oceanic current encircling Antarctica and flowing from west to east. Affected by adjacent landmasses, submarine topography, and prevailing winds, the Antarctic Circumpolar Current is irregular in width and course. Its motion is further complicated by continuous exchange with other water masses at all depths. The volume of transport south of latitude 40° S is thought to be at least 25,000,000 cubic m (880,000,000 cubic feet) per second.

Antarctic Ocean, also called SOUTHERN OCEAN, the southern portions of the Pacific, Atlantic, and Indian oceans and their tributary seas surrounding Antarctica. Unbroken by any other continental landmass, the Antarctic Ocean's narrowest constriction is the Drake Passage, 600 miles (1,000 km) wide, between South America and the tip of the Antarctic Peninsula. The structure of the ocean floor includes a continental shelf usually less than 160 miles (257 km) wide that attains its maximum width of more than 1,600 miles (2,570 km) in the vicinity of the Weddell and Ross seas. There are oceanic basins farther north that are as much as 14,765 feet (4,500 m) deep, defined by oceanic rises and often marked by ranges of abyssal hills. There are also narrow oceanic trenches with high relief marking the sides of the trenches, such as the South Sandwich Trench on the eastern side of the South Sandwich Islands. Other relief features include oceanic plateaus that rise from the oceanic basins to depths of less than 6,560 feet (2,000 m) below sea level and form rather flat regions, which are often covered by relatively thick sedimentary deposits. The most extensive such plateau is the Campbell, or New Zealand, Plateau, which rises southeast of New Zealand and extends southward beyond the Campbell Islands.

The flow of currents in the Antarctic is complex. Water cooled by the coastal ice masses of the Antarctic continent sinks and flows northward along the ocean bottom and is replaced at the surface by an equal volume of warmer water flowing south from the Indian, Pacific, and Atlantic oceans. The meeting point of the two is the Antarctic Convergence, where

conditions favour the development of phytoplankton, consisting of diatoms and other single-celled plants. The ocean's most important organism in the higher food chain is the small, shrimp-like krill. Animals on the sea bottom of the near-shore zone include the sessile hydrozoans, corals, sponges, and bryozoans, as well as the foraging, crab-like sea spiders and isopods, the annelid worm polychaete, echinoids, starfish, and a variety of crustaceans and mollusks. At sea bottom there are also eelpouts, sea snails, rat-tailed fishes, and codlike fishes. Rare nonbony types of fish include hagfish and skates. Many species of deep-sea fish are known south of the Antarctic Convergence, but only three, a barracuda and two lantern fishes, seem to be confined to this zone.

Antarctic Peninsula, also called PALMER PENINSULA, GRAHAM LAND, or TIERRA DE O'HIGGINS, peninsula claimed by Britain as part of the British Antarctic Territory and also claimed by Chile and Argentina. It forms an 800-mile (1,300-kilometre) northward extension of Antarctica toward the southern tip of South America. The peninsula is ice-covered and mountainous, the highest point being Mount Jackson (13,750 feet [4,191 m]). Marguerite Bay indents the west coast, and Bransfield Strait separates the peninsula from the South Shetland Islands to the north. Many other islands and floating ice shelves lie off the coast. One of the first recorded sightings of Antarctica occurred on Jan. 30, 1820, when William Smith, a sealer, and Edward Bransfield, of the Royal Navy, sailed through what is now Bransfield Strait and saw the Antarctic Peninsula. Many nations have operated Antarctic Survey stations on the peninsula or adjacent islands.

Antarctic Treaty (Dec. 1, 1959), agreement signed by 12 nations, in which the Antarctic continent was made a demilitarized zone to be preserved for scientific research. The treaty resulted from a conference in Washington, D.C., attended by representatives of Argentina, Australia, Belgium, Britain, Chile, France, Japan, New Zealand, Norway, South Africa, the United States, and the Soviet Union. Later other nations acceded to the treaty.

The treaty did not deny or support national claims to territorial sovereignty in Antarctica, but it did forbid all contracting parties from establishing military bases, carrying on military maneuvers, testing any weapons (including nuclear weapons), or disposing of radioactive wastes in the area. The treaty encouraged the freedom of scientific investigation and the exchange of scientific information and personnel in Antarctica. The treaty bound its members indefinitely, with a review of its provisions possible after 30 years. A protocol to the 1959 treaty was signed in 1991. The agreement banned mineral and oil exploration for 50 years and included regulations for the protection of the Antarctic environment.

Antarctica, fifth in size among the world's continents, lying concentrically about the South Pole, with a landmass almost wholly covered by a vast ice sheet, averaging about 6,500 feet (2,000 m) thick. It is roughly divided into two subcontinents, the larger, East Antarctica, consisting mainly of a high, ice-covered plateau, and West Antarctica, consisting largely of an archipelago of mountainous islands covered and bonded together by ice. The continent is about 5,500,000 square miles (14,200,000 square km) in area and is important as a region of international cooperation in scientific research. The southern portions of the Atlantic, Pacific, and Indian oceans form the Antarctic Ocean around Antarctica.

The article that follows is a summary of significant detail about Antarctica; for fuller treatment of its geography, history, and peoples, see MACROPAEDIA: Antarctica.

For current history, see BRITANNICA BOOK OF THE YEAR.

The land. Antarctica would be essentially circular except for the outflaring Antarctic Peninsula, which reaches toward the southern tip of South America, and for two principal embayments, the Ross Sea and the Weddell Sea. These deep embayments of the southern-most Pacific and Atlantic oceans make the continent somewhat pear-shaped, dividing it into two unequal-sized parts. The larger has been called Greater Antarctica but is generally known as East Antarctica because most of it lies in east longitudes. The smaller, or Lesser, Antarctica, wholly in west longitudes, is generally called West Antarctica. East and West Antarctica are separated by the 1,900-mi- (3,000-km-) long fault-block chain of the Transantarctic Mountains. Antarctica, with an average elevation estimated at between 7,000 and 8,000 ft above sea level, is the world's highest continent. Without its ice, however, it would probably average about 1,500 ft. Vinson Massif, rising to 16,864 ft, in the Sentinel Range is the highest point on the continent.

The ice sheet overlaying the continent contains approximately 7,000,000 cu mi (30,000,000 cu km) of ice and represents about 90 percent of the world's glacial ice. Some of the ice, such as in the Beardmore, Nimrod, and Reedy glaciers, pours as great ice rivers through breaks in the dam of the Transantarctic Mountains to feed the Ross Ice Shelf. A few outlet streams of polar ice—the Mackay, David, and Priestley glaciers—calve, or discharge, icebergs into Ross Sea. General lowering of ice-sheet levels caused some former outlet glaciers to recede and almost vanish from their valleys, producing such spectacular "dry valleys" as the Taylor, Wright, and Victoria valleys near McMurdo Sound. Ice-scarred volcanoes dot western Ellsworth Land and Marie Byrd Land sectors of the Antarctic Peninsula and the Scotia Arc.

Many parts of the deep embayments of the Ross and Weddell seas are covered by ice shelves, or ice sheets floating on the sea. These shelves—the Ross Ice Shelf and the Ronne and Filchner ice shelves—together with other shelves around the continental margins constitute about 10 percent of the area of Antarctic ice. Around the Antarctic coast, shelves, glaciers, and ice sheets continually calve icebergs into the seas.

By far the coldest continent, Antarctica's coldest winter temperatures range from -128.6°F (-89.2°C)—the world's lowest recorded temperature, measured at Vostok Station on July 21, 1983, on the high inland ice sheet—to -76°F (-60°C) near sea level. Mean temperatures of the coldest months are -4° to -22°F (-20° to -30°C) on the coast, and -40° to -94°F (-40° to -70°C) in the interior, the coldest period on the polar plateau being usually in August just before the return of the Sun. Whereas midsummer temperatures may reach as high as 59°F (15°C) on the Antarctic Peninsula, those elsewhere are usually much lower, ranging from a mean of about 32°F (0°C) on the coast to between -4° and -31°F (-20° and -35°C) in the interior. Fierce winds characterize most coastal regions, particularly of East Antarctica. Despite the tremendous volume of potential water stored as ice, Antarctica must be considered as one of the world's great deserts; the average precipitation (water equivalent) is only about 2 in. (50 mm) per year over the polar plateau, though considerably more, perhaps 10 times as much, falls in the coastal belt. During Antarctic winters, freezing of the

surrounding sea effectively more than doubles the size of the continent.

The cold-desert climate of Antarctica supports only a small community of cold-tolerant land plants that are capable of surviving lengthy winter periods of total or near-total darkness. The continent's plants include lichens, mosses and liverworts, molds, yeasts, other fungi, freshwater algae, and bacteria. The absence of mammalian land predators and the rich offshore food supply make Antarctic coasts a haven of immense seabird rookeries. About 45 species of birds live south of the Antarctic Convergence, but only three—the emperor penguin, Antarctic petrel, and South Polar (McCormick's) skua—breed exclusively on the continent. Only two of the penguin species, the emperor and Adélie, are distributed widely around the continent. The Antarctic waters are home to the copious shrimplike krill, a major food source for whales, fish, and birds. Antarctic perches are the main sea-bottom species. Antarctic native mammals are all marine and include the fur, Weddell, crabeater, leopard, and elephant seals as well as porpoises, dolphins, and whales. Among the whale species are the killer whale, sperm whale, and rare bottle-nosed, or beaked, whale.

A great variety of metal minerals associated with ore deposits on other southern continents are reported from Antarctica and include antimony, chromium, copper, gold, lead, molybdenum, tin, zinc, and uranium. Large reserves of iron have been found near the Prince Charles Mountains of East Antarctica. None of these mineral deposits is in a location or of size and grade that approaches economic utility. Antarctic coals have long been known. The deposits in the Transantarctic Mountains, belonging to one of the world's most extensive coalfields, range from semianthracite to anthracite and even to natural coke.

Since the late 1950s a small tourist industry has included yearly visits by cruise ships at scientific stations and at penguin rookeries. Commercial sightseeing flights over the continent began in the mid-1970s.

History. The Russian expedition leader Fabian Gottlieb von Bellingshausen, the Englishman Edward Bransfield, and the American Nathaniel Palmer all claimed first sightings of the continent in 1820. The period to about 1900 was one dominated by exploitation of Antarctic and sub-Antarctic seas, particularly along Scotia Ridge. Sealing vessels of many nations, principally U.S. and British, participated in hunting that eventually led to near extinction of the southern fur seal. Many also hunted whales, but the less profitable whaling industry peaked following World War I, after sealing had declined. Among the geographic and scientific expeditions that stand out during this period are those of Bellingshausen, commanding Russian ships in a circumnavigation of Antarctica in 1819–21; Bransfield, on a British expedition charting part of the Antarctic Peninsula in 1819–20; Dumont d'Urville, on a French expedition in 1837–40, when Adélie Land was discovered and claimed for France; Charles Wilkes, on a U.S. naval expedition in 1838–42 exploring a large section of the East Antarctic coast; and James Clark Ross, on a British expedition in 1839–43, which discovered the Ross Sea and Ross Ice Shelf, as well as the coast of Victoria Land.

The first two decades of the 1900s are known as the "heroic era" of Antarctic exploration. A scientific party under Carsten E. Borchgrevink spent the winter of 1899 camped at Cape Adare, for the first planned overwintering on the continent. Sledge probes deep into the interior were made by Robert F. Scott on the British National Antarctic "Discovery" Expedition (1901–04) and by Ernest Henry Shackleton on the British Antarctic "Nimrod" Expedition (1907–09) from base camps on Ross Island. The south magnetic pole was

reached in 1909 on the high ice-plateau of Victoria Land by T.W.E. David and Douglas Mawson on a sledge journey from Cape Royds. The South Pole of the Earth's rotation was reached on Dec. 14, 1911, by the Norwegian Roald Amundsen and, a month later, on Jan. 17, 1912, by Scott; all the members of Scott's party perished on the return march.

Between the two World Wars, aircraft began to be used in Antarctic exploration. The American naval officer Richard E. Byrd on Nov. 29, 1929, was the first to fly over the South Pole. Lincoln Ellsworth, an American, and Herbert Hollick-Kenyon, a Canadian pilot, made the first aerial crossing of the continent in 1935.

The first half of the 20th century was also the colonial period in the history of Antarctica. Between 1908 and 1942, seven nations decreed sovereignty over pie-shaped sectors of the continent; many other nations carried out Antarctic exploration without lodging formal territorial claims. By the mid-1950s, stations of one type or another had been established on the continent by Chile, Argentina, Britain, Australia, and France. During the International Geophysical Year (IGY) of 1957–58, 12 nations established more than 50 overwintering stations on the continent for cooperative scientific study. In 1961 the Antarctic Treaty (*q.v.*), which reserved Antarctica for free and nonpolitical scientific investigation, entered into full force. Since then, there has been growth in the number and nature of cooperative international scientific projects in Antarctica.

Antares, also called ALPHA SCORPII, red, semiregular variable star, with apparent visual magnitude about 0.9, the brightest star in the zodiacal constellation Scorpius and one of the largest known stars, having several hundred times the diameter of the Sun and several thousand times the Sun's luminosity. It has a fifth-magnitude blue companion. Antares lies about 400 light-years from the Earth. The name seems to come from a Greek phrase meaning "rival of Ares" (*i.e.*, rival of the planet Mars) and was probably given because of the star's colour and brightness.

antbird, family name FORMICARIIDAE, any of numerous birds of the American tropics (order Passeriformes). There are about 230 species in more than 50 genera. Like their near relatives the Furnariidae, antbirds are highly diverse; all are of small to medium size (9.5 to 37 centimetres [4 to 14 inches]), with drab, fluffy

Barred antshrike (*Thamnophilus doliatus*)
Paul Schwartz

plumage (sexes usually unlike); short, rounded wings; variable but often rather stout bill with a hooked (sometimes also notched) tip; strong legs; and front toes partly joined at the base. Most make cup-shaped nests. All have loud, usually unmusical voices that may be heard in echo duets. Antbirds are insectivorous,

and many species habitually follow columns of marching ants. Beyond these few generalizations, subgroups are vaguely characterized by popular names likening them to birds of other families—antwren, antpitta, antshrike, ant-vireo, ant thrush (the former name of the group); still other antbirds are called bare eyes, fire eyes, and bush bird.

The gnateaters of the genus *Conopophaga*, eight or nine species of moderately long-legged, short-tailed ground birds, were formerly grouped with the genus *Corythopis* (the antpipits) in a separate family (Conopophagidae), but an increasing number of authorities now include *Conopophaga* in the Formicariidae and *Corythopis* in Tyrannidae.

anteater, any of four species of toothless, insect-eating mammals, family Myrmecophagidae, placed with the armadillos and sloths in the order Edentata. Anteaters are found in tropical savannas and forests from Mexico to northern Argentina and Uruguay. They are densely furred, long-tailed animals, with long skulls and tubular muzzles. The mouth opening is small and the tongue long and wormlike. The salivary glands are large and secrete sticky saliva. Anteaters live alone or in pairs and feed mainly on ants and termites. They obtain their prey by inserting their long, sticky tongues into insect nests torn open by the long, sharp, curved claws of their forefeet.

The giant anteater (*Myrmecophaga tridactyla*), sometimes called ant bear, is the largest of the anteaters. Gray with a diagonal, white-bordered black stripe on each shoulder, it attains a length of about 1.8 m (6 feet), including the long, bushy tail, and weighs up to 25 kg (55 pounds). It is mainly diurnal, but in inhabited areas it is most active at night. It walks with a shuffle, bearing its weight on the knuckles of its forelimbs. When harried, it is capable of a galloping run. Like the other anteaters, it grasps and claws when forced to fight. The female bears a single young after a gestation period of about 190 days.

Unlike the giant anteater, the lesser anteater, or tamandua (*Tamandua*), and the two-toed anteater (*Cyclopes didactylus*) are arboreal and mainly nocturnal. Members of both genera have prehensile tails, which they use in climbing. Depending on the authority, there are one or two species of lesser anteaters. These animals are often tan with a blackish "vest" around the shoulders and on the body; some are entirely tan or entirely blackish. Lesser anteaters are about 1.2 m (about 4 feet) long

Lesser anteater (*Tamandua tetradactyla*)

Robert C. Hermes—Annas Photo Features

including the tail. They have shorter fur and shorter muzzles than the giant anteater.

The two-toed, silky, or dwarf, anteater is the smallest and least-known member of the family. It attains an overall length of about 37 cm (15 inches), about one-half of which is tail. It has a silky, yellowish coat and has two clawed toes on each forefoot (the giant and lesser anteaters have four).

Animals that were once grouped with the anteaters include the aardvark; the pangolin, or scaly anteater; the numbat, or banded anteater; and the echidna, or spiny anteater.

Antelami, Benedetto (b. c. 1150, probably Lombardy [Italy]—d. c. 1230, Parma), Italian sculptor and architect considered to have been one of the greatest of his time.

Little is known of his life. It is believed that he served his apprenticeship in sculpture at Saint-Trophime in Arles, Fr., and that this service may have influenced his sensitivity to French (particularly Provençal) stylistic developments. It is thought that he also belonged to the *magistri Antelami*, a civil builders' guild located in the Lake Como region of present-day northern Italy. One of his earliest signed works is the *Deposition from the Cross*, a relief sculpture (dated 1178) located in the right transept of the cathedral of Parma. Between 1188 and 1218 Antelami worked on various sculptural and architectural elements of the cathedral of Borgo San Donnino (now Fidenza) near Parma. In 1196 he started work on the construction and decoration of the magnificent baptistery of Parma cathedral (completed 1270). His last work is believed to have been the decoration and (at least in part) the construction of the church of Sant'Andrea at Vercelli, the architecture of which successfully combined Tuscan Romanesque with Gothic characteristics (such as flying buttresses, rose windows, and ribbed vaulting) and won him lasting renown.

antelope, any of numerous Old World grazing or browsing mammals belonging to the family Bovidae (order Artiodactyla), which also includes sheep, goats, and cattle. The pronghorn of North America, though a member of the family Antilocapridae, is also sometimes referred to as an antelope. The term has no precise zoological definition.

Antelopes are even-toed, hooved mammals that typically are swift, slender, and graceful plains dwellers. Most are African; the others, except for the North American pronghorn, are Eurasian. Antelopes range in shoulder height from 25 cm (10 inches) in the royal antelope (*Neotragus pygmaeus*) of Africa to 175 cm (70 inches) in the giant eland (*Taurotragus derbianus*), also of Africa. The male antelope, and sometimes the female, bears distinctive, backwardly curved horns. The horns vary in form, some being short and spikelike, as in the duikers (*Cephalophus* and *Sylvicapra*); some spirally twisted, as in the kudu (*Tragelaphus*); and some long and lyre-shaped, as in the impala (*Aepyceros*). The Arabian oryx (*Oryx leucoryx*), the giant sable antelope (*Hippotragus niger varians*), and other antelopes are almost extinct.

For information on related animals, see duiker; eland; impala; kudu; oryx; pronghorn; royal antelope; sable antelope.

antenna, component of radio, television, and radar systems that directs incoming and outgoing radio waves. Antennas are usually metal and have a wide variety of configurations, from the mastlike devices employed for radio and television broadcasting to the large parabolic reflectors used to receive satellite signals and the radio waves generated by distant astronomical objects.

The first antenna was devised by the German physicist Heinrich Hertz. During the late 1880s he carried out a landmark experiment to test the theory of the British mathemati-

cian-physicist James Clerk Maxwell that visible light is only one example of a larger class of electromagnetic effects that could pass through air (or empty space) as a succession of waves. Hertz built a transmitter for such waves consisting of two flat, square metallic plates, each attached to a rod, with the rods in turn connected to metal spheres spaced close together. An induction coil connected to the spheres caused a spark to jump across the gap, producing oscillating currents in the rods. The reception of waves at a distant point was indicated by a spark jumping across a gap in a loop of wire.

The Italian physicist Guglielmo Marconi, the principal inventor of wireless telegraphy, constructed various antennas for both sending and receiving, and he also discovered the importance of tall antenna structures in transmitting low-frequency signals. In the early antennas built by Marconi and others, operating frequencies were generally determined by antenna size and shape. In later antennas frequency was regulated by an oscillator, which generated the transmitted signal.

More powerful antennas were constructed during the 1920s by combining a number of elements in a systematic array. Metal horn antennas were devised during the subsequent decade following the development of waveguides that could direct the propagation of very high-frequency radio signals.

Over the years, many types of antennas have been developed for different purposes. An antenna may be designed specifically to transmit or to receive, although these functions may be performed by the same antenna. A transmitting antenna, in general, must be able to handle much more electrical energy than a receiving antenna. An antenna also may be designed to transmit at specific frequencies. In the United States, amplitude modulation (AM) radio broadcasting, for instance, is done at frequencies between 535 and 1,605 kilohertz (kHz); at these frequencies, a wavelength is hundreds of metres or yards long, and the size of the antenna is therefore not critical. Frequency modulation (FM) broadcasting, on the other hand, is carried out at a range from 88 to 108 megahertz (MHz). At these frequencies a typical wavelength is about 3 metres (10 feet) long, and the antenna must be adjusted more precisely to the electromagnetic wave, both in transmitting and in receiving. Antennas may consist of single lengths of wire or rods in various shapes (dipole, loop, and helical antennas), or of more elaborate arrangements of elements (linear, planar, or electronically steerable arrays). Reflectors and lens antennas use a parabolic dish to collect and focus the energy of radio waves, in much the same way that a parabolic mirror in a reflecting telescope collects light rays. Directional antennas are designed to be aimed directly at the signal source and are used in direction-finding.

Antenor (fl. c. 540–500 BC), Athenian sculptor of the late Archaic period who carved the first group of statues of the tyrannicides Harmodius and Aristogiton for the Athenian agora and a kore (a freestanding figure of a maiden) for the Acropolis (now in the Acropolis Museum in Athens).

Antenor's sculpture of the tyrannicides probably dates from shortly after 510. In 480, when Xerxes I captured Athens, the sculpture was carried off to Susa, and no copies of it have been found. Antenor's kore, which probably dates from c. 530 to 520, is one of the finest examples of late Archaic sculpture. The greater part of this figure was found in 1886, northwest of the Erechtheum, on the Acropolis. It is of marble, larger than life, and traces of its painted colour remain.

Antequera, city, Málaga province, in the autonomous community (region) of Andalusia, southern Spain, northwest of Málaga, at the foot of the Sierra del Torcal. Neolithic dolmens (Menga, Viera, and El Romeral) attest to prehistoric occupation of the site. The city, known to the Romans as Anticaria and to the Moors as Madinah Antakira, was reconquered for Christian Spain by the infante Don Fernando (Ferdinand, regent of Castile) in 1410, after which it served as a religious and seigniorial centre. Examples of its 16th-century architecture include the churches of Santa María la Mayor of San Francisco and of San Sebastián, which houses works of the great Spanish painter Murillo.

Agriculturally based, Antequera produces olives, cereals, fertilizers, sugar, ice cream, Christmas candles, woollen blankets, and cotton goods. Pop. (1998 est.) 40,239.

Antequera, El de (Spanish: He of Antequera), also called EL INFANTE DE ANTEQUERA: see Ferdinand I under Ferdinand (Spain: Aragon).

Anterus, SAINT (b. Greece—d. Jan. 3, 236, Rome; feast day January 3), pope for several weeks at the end of 235 and the beginning of 236. He was elected (possibly Nov. 21, 235) while St. Pontian, his predecessor, was condemned to the Sardinian mines. Anterus was soon prosecuted and sentenced to death. According to the *Liber pontificalis*, he was martyred for having ordered a collection of the acts of the martyrs to be made and included in the archives of the church.

Antes (Slavic nomads): see Antae.

Antheil, George (b. July 8, 1900, Trenton, N.J., U.S.—d. Feb. 12, 1959, New York City), American composer known for his ultramodern music in the 1920s.

Antheil studied with Ernest Bloch in New York. In 1922 he went to Europe, gave piano recitals, and became prominent in the literary and artistic circles of the Parisian avant-garde. Antheil's most celebrated work, *Le Ballet mécanique*, scored for player pianos, automobile horns, electric bells, and airplane propellers, produced a hostile outcry in Paris (1926) and New York (1927); on its revival in 1954 it was considered fairly tame. In 1936 Antheil moved to Hollywood and subsequently produced many film scores, among them *Tokyo Joe* (1949), *Angels over Broadway* (1940), and *Fighting Kentuckians* (1950). After about 1939 he abandoned the avant-garde style for a mixture of Classicism, Romanticism, and Impressionism. His other works include six symphonies; the ballet *Capital of the World* (1953); chamber music; and the operas *Transatlantic* (1930), *Helen Retires* (1934), *Volpone* (1953), and *The Wish* (1955). He wrote an autobiography, *Bad Boy of Music* (1945).

anthelmintic, any drug that acts against helminthic infections, *i.e.*, those caused by parasitic worms. The term vermifuge is often applied to remedies used to remove intestinal worms; only rarely do the agents directly kill the parasites. No anthelmintic is completely effective, completely without toxic effect upon the host, or equally active against all worms.

Most of the anthelmintics used in human medicine before World War II were replaced by more efficacious and less toxic drugs after the war. Anthelmintics have been developed to improve livestock production. Hygromycin is an antibiotic used as a feed additive to eliminate or reduce the large roundworms (*Ascaris*), nodular worms (*Oesophagostomum*), and whipworms (*Trichuris*) of swine, and the large roundworms (*Ascaridia*) and cecal worms (*Heterakis*) of poultry.

Intestinal worm infections in general are

more easily treated than those in other locations in the body. Because the worms need not be killed by the drug and the drug need not be absorbed when given by mouth, there is usually a wider margin of safety than with drugs for worm infections in other sites. Piperazine, introduced into human medicine about 1950 and shortly thereafter into veterinary medicine, relaxes the large intestinal roundworms (*ascarids*) and pinworms (*oxyurids*) of man and domesticated animals so that they are eliminated with the feces. Piperazine, still extensively used for infections of domesticated animals, including poultry, was superseded by the more active pyriminium pamoate for the treatment of human pinworm infection.

Other anthelmintics include dithiazanin, used for the treatment of the *Strongyloides* and whipworm of man and dog; thiabendazole, used primarily for the treatment of several nematodes of cattle, horses, and sheep but also used for treatment of whipworms and *Strongyloides* of man; tetramisole, used in some European countries, being, unlike most anthelmintics, apparently almost as effective against larval stages of intestinal nematodes as against adult worms in cattle, sheep, and poultry.

Tetrachlorethylene, introduced in 1925 for the treatment of hookworms of man and dogs, is still used for the so-called American hookworm (*Necator americanus*) of man but was superseded by bephenium hydroxynaphthoate for the treatment of the European hookworm (*Ancylostoma duodenale*) of man and by disphenol for the treatment of canine hookworm (*Ancylostoma caninum*). Phenothiazine, introduced in the 1930s, is still used against the wireworm (*Haemonchus contortus*) of sheep and cattle. Quinacrine, an early synthetic World War II antimalarial later superseded, is now often used as an anthelmintic for the removal of the large tapeworms of man; it is also useful in the treatment of tapeworm infection of dogs. Other compounds used for intestinal worms of domesticated animals, but rarely of man, include arecoline hydrobromide, *n*-butyl chloride, carbon disulfide, copper sulfate, dichlorophen, lead arsenate, phthalofyne, and toluene. Dibutyltin dilaurate is used for tapeworm infections in poultry.

anthem (Greek *antiphōna*: "against voice"; Old English *antefn*: "antiphon"), choral composition with English words, used in Anglican and other English-speaking church services. It developed in the mid-16th century in the Anglican Church as a musical form analogous to the Roman Catholic motet (*q.v.*), a choral composition with a sacred Latin text.

At first, unaccompanied choral writing, or full anthem, was the norm. In the 16th century the growth of the verse anthem (which used a solo vocal part and eventually many soloists as well as a choir) encouraged the use of instrumental accompaniment, either by the organ or by instrumental groups, such as wind instruments or viols. Shortly after the restoration of the monarchy in 1660 it was common, at least in the royal chapel, to perform anthems with orchestral accompaniment. In the 1700s the full anthem ousted to some extent the verse anthem, although solo passages were occasionally used for special effect.

Both full and verse anthems frequently utilized antiphony, the alternation of two half choirs. These were usually referred to as decani (the dean's side) and cantoris (the precentor's, or choirmaster's, side). The contrast of the half choirs and, in elaborate verse anthems, of subsections for soloists, instruments, or choir, provided a subtle effect of fluctuating tone colour and sonority that often reflected the mood or sense of the text. Verse anthems alternating soloists, instrumental passages, and choir often resembled the cantatas used in Lutheran worship. Among notable composers of anthems are Thomas Tomkins, Henry Pur-

cell, George Frideric Handel, Samuel Sebastian Wesley, and Ralph Vaughan Williams.

anthemion, design consisting of a number of radiating petals, developed by the ancient Greeks from the Egyptian and Asiatic form known as the honeysuckle or lotus pal-

Anthemion molding on the Erechtheum, the Acropolis, Athens, designed by Mnesicles, 5th century BC

Alison Frantz

mette. The anthemion was used widely by the Greeks and Romans to embellish various parts of ancient buildings. The Greeks originally decorated only pottery with the motif, but they soon adapted it to ornament architecture. The single-palmette form appears on acroteria (decorative pedestals), antefixes (roof or cornice elements), and the top of vertical stelae. The continuous pattern of alternating lotus and palmette springing from connecting spirals decorates especially the cyma recta molding of the cornice.

Anthemius (d. 472), Western Roman emperor who reigned from April 12, 467, until July 11, 472.

The son-in-law of the Eastern emperor Marcian, Anthemius was appointed to his office by Marcian's successor, Leo I, who wanted help in attacking the Vandals in North Africa. The powerful patrician Ricimer, kingmaker of the Western Empire, accepted Anthemius with the stipulation that his daughter, Alypia, marry Ricimer. Anthemius' popularity in Italy suffered, however, because as a Greek and a philosopher he was suspected of wanting to restore paganism. The vast expedition against the Vandals ended in utter defeat for the Romans. Ricimer and Anthemius quarrelled, and, in 472, the patrician besieged the Emperor in Rome. Anthemius' forces were defeated; he was found disguised as a beggar and beheaded.

Anthesteria, one of the several Athenian festivals in honour of Dionysus, the wine god, held annually for three days in the month of Anthesterion (February–March) to celebrate the beginning of spring and the maturing of the wine stored at the previous vintage. On the first day libations were offered to Dionysus from the newly opened casks. The second day was a time of popular merrymaking, but the state performed a secret ceremony in a sanctuary of Dionysus in the Lenaeum, in which the wife of the king archon went through a ceremony of marriage to Dionysus. On these days, it was believed, the souls of the dead came up from the underworld and walked abroad; people chewed leaves of whitethorn and smeared their doors with tar to protect themselves from evil. The third day was a festival of the dead.

Anthimus I, also called ANTHIM OF TREBIZOND (fl. 6th century), Greek Orthodox patriarch of Constantinople (reigned 535–536), the last notable Byzantine churchman explicitly to advocate Monophysitism (*see* Monophysite).

As bishop of Trebizond Anthimus participated in discussions at Constantinople in 532, to effect religious and political unity between East and West. Although avowing support for the orthodox party, Anthimus harboured Monophysite sentiments and corresponded with the chief theoreticians of that doctrine, the patriarchs Severus of Antioch and Theodosius of Alexandria. On the death of Patriarch Epiphanius in June 535, the empress Theodora, who was sympathetic toward

the Monophysites, had Anthimus appointed patriarch of Constantinople. While promising to promote orthodoxy in alliance with Pope Agapetus I, Anthimus secretly furthered the Monophysite cause. Discovering Anthimus' real beliefs on a visit to Constantinople in early March 536, Pope Agapetus convened a synod, broke off ecclesiastical communion with the patriarch, deposed him, and nullified his ministerial power. Anthimus was condemned by the council of Constantinople, and until his death he remained in monastic seclusion under the protection of Empress Theodora. The remains of his writings include his Monophysite tracts and anathemas against orthodox Christological doctrine (on the nature and person of Christ), preserved in the *Thesaurus of Orthodoxy*, by the 12th-century Byzantine historian Nicetas Choniates.

Anthimus VI, original name JOANNIDES (b. c. 1790, Kutali Island, Aegean Sea—d. 1878, Kandilli, near present Istanbul), Eastern Orthodox patriarch of Constantinople who attempted to maintain his ecclesiastical authority over the rebellious Bulgarian Orthodox Church, and, with others, wrote an Orthodox encyclical letter repudiating Roman Catholic overtures toward reunion.

In about 1840 Anthimus, a monk of a monastery on Mt. Athos, in Greece, was chosen metropolitan of Ephesus, near modern Selçuk, Tur. He later became patriarch of Constantinople, reigning for three intervals: 1845–48, 1853–55, and 1871–73. The successive dismissals and reappointments of Anthimus to the patriarchate reflected the policy of the Turkish rulers of reacting sensitively to political events and of preventing the patriarchate from acquiring political strength.

Together with the patriarchs of Alexandria, Jerusalem, and Antioch, Anthimus wrote the *Encyclical of the Patriarchs* (1848), an open letter to the Orthodox world criticizing papal ambitions to exercise authority over the universal Catholic Church as represented in Pope Pius IX's encyclical letter of Jan. 6, 1848, *In Suprema Petri Apostoli Sede* ("On the Supreme Throne of Peter the Apostle"), which invited the Orthodox Church to reunite with the church of Rome.

Anthimus VII TSATSOS (b. c. 1835, possibly Ioännina, Greece—d. December 1913, Halki, Tur.), Eastern Orthodox patriarch of Constantinople (1895–96), theologian, orator, and a leading critic of the Roman Catholic Church.

Like Anthimus VI, his predecessor of a half-century earlier, Anthimus VII is known for his encyclical letter to the Orthodox world refuting a papal encyclical, *Praeclara Gratulationis* ("Splendid Rejoicing") of Pope Leo XIII (June 20, 1894), which proposed grounds for the reunion of the Orthodox and Roman churches. Besides citing the traditional Eastern arguments attacking Western corruption of early Christian doctrine, Anthimus made new charges occasioned by Roman Catholic teaching formulated during the 19th century. He accused the Latin Church of introducing novel approaches to Christian faith, viz., Pope Pius IX's solemn pronouncement in 1854 of the dogma of the Virgin Mary's Immaculate Conception (i.e., the divine act exempting her from original sin) and the first Vatican Council's (1869–70) decree on papal infallibility, which held as necessary for salvation belief in the pope's exemption from error when treating of doctrine and morality.

Anthimus OF IBERIA, Romanian ANTIM IVIREANUL (d. 1716, probably Rumelia), metropolitan of Walachia (now part of Romania), linguist, typographer, and ecclesiastical writer who contributed greatly to the development of the Romanian language and literature by his translation and printing of biblical and liturgical texts and by his own

writings in ethics and asceticism. He is also honoured as one of the earliest Romanian nationalist leaders.

The superior of the Walachian monastery of Snagov, he was later chosen bishop of Ramnic and in 1708 became metropolitan of all of Walachia. Famed for his precise typography and artistic frontispieces, usually with floral designs, Anthimus produced a wealth of material in Romanian and Greek, including the New Testament Gospels (1693), which he also translated in a Romanian version in 1697. Desiring to give his people a guide for a Christian life, he compiled the *Margaritare* ("Pearls"), an anthology of the moral and ascetic letters of the 4th-century Greek church father St. John Chrysostom. A proponent of traditional Orthodoxy, he edited in 1699 the *Orthodoxa Confessio Fidei* ("The Orthodox Confession of Faith") by the 17th-century Ukrainian theologian Peter Moghila.

In addition to his own sermons, Anthimus also wrote in Romanian the *Didahii* ("Teachings"), a two-volume collection of moral exhortations containing historically important descriptions critical of the luxurious life of the Walachian boyars (aristocracy). The *Didahii* also is a unique source document on 18th-century Balkan social life.

As an advocate of Walachian nationalism, Anthimus urged his ruler, Prince Constantin Brâncoveanu, to assist the Russian tsar Peter I the Great in his unsuccessful campaign of 1711 against the Turks. When war broke out between Austria and Turkey in 1716, the Greek administrator for the Turkish regime of Walachia, Nikolaos Mavrokordatos, ordered Anthimus returned to Constantinople under guard. During the journey he was executed by drowning, probably in the Tundzha River. The Antim monastery was erected in Bucharest as a memorial to Anthimus.

anthocorid bug (insect): see flower bug.

anthomyiid fly, a common insect of the family Anthomyiidae (order Diptera) resembling the housefly in appearance. The lesser housefly (*Fannia canicularis*) and the latrine fly (*F. scalaris*) are important anthomyiid flies. They breed in filth, can carry diseases, and are often found in the home. Some larvae feed on plants and are serious pests, many are scavengers and live in excrement and decaying material, and others are aquatic. Among the larvae the cabbage maggot (*Hylemya brassicae*), an important pest of Canada and the northern United States, attacks the underground parts of cabbage, cauliflower, broccoli, radishes, and turnips. It was introduced from Europe early in the second half of the 19th century. The best control is treatment of the soil with insecticides. The onion maggot (*H. antiqua*), found in North America, injures onions by feeding on the underground bulb and stem. The adult is a bristly, gray fly about 6 or 7 millimetres (0.2 to 0.3 inch) long with large wings. It is best controlled by chemical applications before planting. The seed-corn maggot (*H. cilicrura*) feeds in corn, pea, and bean seeds, which consequently either develop into weak plants or fail to sprout. This species has a short life cycle and produces from three to five generations each year. Damage caused by the seed-corn maggot can be reduced by delayed planting. Another important pest is the spinach leaf miner (*Pegomya hyoscyomi*). It produces blotches or linear mines (internal passages) on spinach leaves.

Anthoniszoon, Jeroen: see Bosch, Hiëronymus.

Anthony (personal name): see under Antony, except as below.

Anthony MELISSA (fl. 11th century), Byzantine monk, author whose collection of teachings and maxims taken from Sacred Scripture, early Christian writers, and secular authors

promoted a popular Greek Orthodox tradition of moral-ascetical practice.

Anthony, whose surname is derived from the title of his chief work, *Melissa* (Greek: "The Bee"), compiled an anthology based largely on two leading sources for Eastern Orthodox spirituality: the *Hiera Parallēla* ("Sacred Parallels"), commonly credited to the early-8th-century Greek church father John of Damascus, and the *Eklogai* ("Selections"), incorrectly ascribed to the 7th-century Greek master of ascetical theology, St. Maximus the Confessor.

Composed of two books, *Melissa* provides comprehensive extracts from a broad spectrum of early Christian and non-Christian literature, chosen for their relevance to contemplative spirituality and liturgical piety. *Melissa* appears in a turgid 16th-century Latin translation, accompanying the Greek text, in the series by J.-P. Migne (ed.), *Patrologia Graeca*, (vol. 136, 1866). Anthony possibly also wrote an informal work, *Christoithia* ("Good Manners"), designed for the social and moral edification of Greek youth, which gained popularity in Byzantine society. Some historians claim the work is actually that of an 18th-century Greek scholar, Anthony the Byzantine, headmaster of the Greek school in Istanbul, who supposedly in 1720 rendered into literary Greek the *De civilitate morum puerilium* ("On the Civility of Adolescent Manners") by the early-16th-century Humanist Erasmus.

Anthony OF BOURBON, also called ANTHONY OF NAVARRE, French ANTOINE DE BOURBON, or DE NAVARRE, Spanish ANTONIO DE BORBÓN, or DE NAVARRA (b. April 22, 1518—d. Nov. 17, 1562, Andelys, Fr.), king of Navarre, duke of Vendôme, and father of Henry IV of France.

Son of Charles of Bourbon, duke of Vendôme, he married (1548) Jeanne d'Albret, daughter of Henry II, king of Navarre; as sole heir, she brought her husband the title of king of Navarre. Anthony was involved with his brother, Louis I de Bourbon, prince de Condé, in the Huguenot conspiracy of Amboise, but, nevertheless, he survived to be later named lieutenant general of the French armies (1560), having turned Roman Catholic. He commanded the army that besieged Rouen and there received a mortal wound.

Anthony OF EGYPT, SAINT, Anthony also spelled ANTONY, or ANTONIOS (b. c. 251, Koma, near al-Minyā, Heptanomis [Middle Egypt], Egypt—d. Jan. 17?, 356, Dayr Mārī Antonios hermitage, near the Red Sea; feast day January 17), religious hermit and one of the earliest monks, considered the founder and father of organized Christian monasticism. His rule represented one of the first attempts to codify guidelines for monastic living.

A disciple of Paul of Thebes, Anthony began to practice an ascetic life at the age of 20 and after 15 years withdrew for absolute solitude to a mountain by the Nile called Pispir (now Dayr al-Maymūn), where he lived from about 286 to 305. During the course of this retreat, he began his legendary combat against the devil, withstanding a series of temptations famous in Christian theology and iconography. In about 305 he emerged from his retreat to instruct and organize the monastic life of the hermits who imitated him and who had established themselves nearby. When Christian persecution ended after the Edict of Milan (313), he moved to a mountain in the Eastern Desert, between the Nile and the Red Sea, where the monastery Dayr Mārī Antonios still stands. Here he remained, receiving visitors and, on occasion, crossing the desert to Pispir. He ventured twice to Alexandria, the last time (c. 350) to preach against Arianism, a heretical doctrine teaching that Christ the Son is not of the same substance as God the Father.

The early monks who followed Anthony into the desert considered themselves the vanguard of God's army, and, by fasting and performing other ascetic practices, they attempted to attain the same state of spiritual purity and freedom from temptation that they saw realized in Anthony. Anthony's spiritual combats with what he envisioned as the forces of evil made his life one long struggle against the devil. According to St. Athanasius, the bishop of Alexandria, the devil's assault on Anthony took the form of visions, either seductive or horrible, experienced by the saint. For example, at times, the devil appeared in the guise of a monk bringing bread during his fasts, or in the form of wild beasts, women, or soldiers, sometimes beating the saint and leaving him in a deathly state. Anthony endured many such attacks, and those who witnessed them were convinced they were real. Every vision conjured up by Satan was repelled by Anthony's fervid prayer and penitential acts. So exotic were the visions and so steadfast was Anthony's endurance that the subject of his temptations has often been used in literature and art, notably in the paintings of Hiëronymus Bosch, Matthias Grünewald, and Max Ernst.

From these psychic struggles Anthony emerged as the sane and sensible father of Christian monasticism. The rule that bears his name was compiled from writings and discourses attributed to him in the *Life of St. Antony* (by Athanasius) and the *Apophthegmata patrum* and was still observed in the 20th century by a number of Coptic and Armenian monks.

Anthony's popularity as a saint reached its height in the Middle Ages. The Order of Hospitallers of St. Anthony was founded near Grenoble, France (c. 1100), and this institution became a pilgrimage centre for persons suffering from the disease known as St. Anthony's fire (or ergotism). The black-robed Hospitallers, ringing small bells as they collected alms, were a common sight in many parts of western Europe. The bells of the Hospitallers, as well as their pigs—allowed by special privilege to run free in medieval streets—became part of the later iconography associated with St. Anthony.

BIBLIOGRAPHY. Athanasius, *The Life of Antony and the Letter to Marcellinus* (1980), was written by a contemporary; this translation includes useful prefatory material.

ANTHONY OF KIEV, also called ANTHONY OF PECHERSK (b. Ukraine—d. 1073, Kiev), founder of Russian monasticism through the institution of the Greek Orthodox ideal of the contemplative life.

Seeking a solitary life, Anthony became a monk about 1028 at the Greek Orthodox monastery of Esphigmenon on Mount Athos, in Greece. According to an account contained in the 12th-century *The Russian Primary Chronicle* (*Povest vremennykh let*), Anthony was counseled by his abbot to carry the Athonite monastic tradition to Russia. He consequently returned to his Ukrainian homeland, where he settled in a cave on the side of Mount Berestov, overlooking the Dnieper River. His fame as a holy hermit and wonder worker spread throughout the region, and by the mid-11th century the number of disciples warranted a larger cave on the same site to house them. When the community of hermits had grown to 15, requiring the construction of a church and refectory, Anthony resigned as spiritual leader and retired to another grotto. Soon the prince of Kiev, Izyaslav, ceded Mount Berestov to the monks, and Anthony laid the foundation for the Pecherskaya Lavra (Monastery of the Caves), an institution that later acquired a reputation as the cradle of

Russian monasticism. Reverting to his Athonite training, he sent to Constantinople (modern Istanbul) for architects to construct the new monastery complex at the mountain.

By such a foundation Anthony established the basis for the Russian assimilation of the three elements of Byzantine monasticism: the writings of the early Egyptian and Palestinian monks, the eremitical practices of Mount Athos, and the communal spirituality in the rule of Constantinople's Stoudion monastery. As described in *The Russian Primary Chronicle*, he favoured the solitary life, marked by superhuman efforts to suppress human passions in a demon-haunted world. Reflecting the Byzantine ascetical tradition, Anthony expressed the basic tension, never fully resolved, between the contemplative's search for God through asceticism and the social responsibilities of the hermit. He realized the moral and psychological pitfalls of solitude and consequently provided hermitages near the monastery. Anthony's institution exerted a wide influence on the Russian Orthodox church and later evolved into the cenobitical (community life) ideal out of which some 50 monks became bishops by the year 1250.

The latter part of Anthony's life was marked by a strained relationship with Izyaslav, who suspected him of conspiring with a rival lord during the stormy years following the death, in 1054, of the forceful grand prince of Kiev, Yaroslav I the Wise.

ANTHONY OF NOVGOROD, original name DOBRYNIA JADREJKOVIČ (fl. 13th century), monk and archbishop of Novgorod, Russia (1211–c. 1231), noted for his political and commercial diplomacy with the West and for the earliest cultural and architectural chronicle of Constantinople (modern Istanbul) and a résumé of the Greek Orthodox liturgy at the basilica of Hagia Sophia (Church of the Holy Wisdom).

Anthony's importance derives mainly from his *Pilgrim's Book*, written during a visit to Constantinople about 1200. The book is unique for information on late 12th-century Constantinople and as the most comprehensive source on its archaeology and religious culture before the French and Venetian pillage (1204) during the Fourth Crusade.

ANTHONY OF PADUA, SAINT, Anthony also spelled ANTONY, Italian SAN ANTONIO DI PADOVA, original name FERNANDO (b. 1195, Lisbon, Port.—d. June 13, 1231, Arcella, Verona [now in Italy]; canonized 1232; feast day June 13), Franciscan friar, doctor of the church, and patron of the poor. Baptized Ferdinand, he joined the Augustinian canons (1210) and probably became a priest. He joined the Franciscan order in 1220, hoping to preach to the Saracens and be martyred. Instead, he taught theology at Bologna, Italy, and at Montpellier, Toulouse, and Puy-en-Velay in southern France, winning great admiration as a preacher. He died en route to Padua, Italy, where he is buried.

Anthony was the most celebrated of St. Francis of Assisi's followers and had the reputation of a miracle worker. On Jan. 16, 1946, Pope Pius XII declared him a doctor of the church. Padua and Portugal claim him as their patron saint, and he is invoked for the return of lost property. In art he is shown with a book, a heart, a flame, a lily, or the child Jesus. Among his authentic writings are sermons for Sundays and feast days, published at Padua, 1895–1913.

Anthony, Katharine (Susan) (b. Nov. 27, 1877, Roseville, Ark., U.S.—d. Nov. 20, 1965,

Katharine Anthony
AP/Wide World Photos

New York, N.Y.), American biographer best known for *The Lambs* (1945), a controversial study of the British writers Charles and Mary Lamb. The greater portion of her work examined the lives of notable American women.

A college teacher of geometry, Anthony was deeply interested in psychiatry. Eventually this interest came to shape her approach to biography, and her books centred increasingly on the psychological development and motivation of her subjects. Some of these works include *Margaret Fuller, A Psychological Biography* (1920); *Catherine the Great* (1925); *Louisa May Alcott* (1938); *Dolly Madison, Her Life and Times* (1949); and *Susan B. Anthony, Her Personal History and Her Era* (1954). Anthony's readers were scandalized by *The Lambs*, subtitled *A Story of Pre-Victorian England*, in which she theorized that incestuous feelings within the Lamb family were reflected in the lives and literary collaborations of Charles Lamb and his sister, Mary. As with her previous biographies, *The Lambs* brought a mixed response from critics, many of whom objected to her unscholarly approach to biography and her unprofessional application of psychoanalytic theory.

Anthony, Susan B., in full SUSAN BROWN-WELL ANTHONY (b. Feb. 15, 1820, Adams, Mass., U.S.—d. March 13, 1906, Rochester, N.Y.), pioneer crusader for the woman suffrage movement in the United States and president (1892–1900) of the National American Woman Suffrage Association. Her work helped pave the way for the Nineteenth Amendment (1920) to the Constitution, giving women the right to vote.

A tone of independence and moral zeal pervaded Anthony's childhood home, dominated by her father, Daniel Anthony, a Quaker Abolitionist and cotton manufacturer. She was a precocious child and learned to read and write at the age of three. After the family moved from Massachusetts to Battenville, N.Y., in 1826, she attended a district school, then a school set up by her father, and finally a boarding school near Philadelphia.

After teaching at a female academy in upstate New York (1846–49), she settled in her family home, now near Rochester, N.Y., and began her first public crusade, on behalf of temperance. Discouraged by the limited role that women were allowed in the established temperance movement, Anthony helped found the Woman's State Temperance Society of New York, one of the first organizations of its kind. From 1852 on, she joined her friends Elizabeth Cady Stanton and Amelia Bloomer in campaigns for women's rights, even for a time donning the "bloomer" costume of skirt and loose trousers as a sign of protest against the restrictiveness of women's clothing. After 1854 she devoted herself with vigour and determination to the antislavery movement, serving from 1856 to the outbreak of the Civil

Susan B. Anthony

War (1861) as an agent for the American Anti-Slavery Society. Later, collaborating with Stanton, she published the New York liberal weekly *The Revolution* (1868–70) and, calling for equal pay for women, helped organize the New York Working Women's Association. In 1872, demanding for women the same civil and political rights extended to male blacks under the Fourteenth and Fifteenth amendments, she led a group of women to the polls in Rochester to test the right of women to vote. She was arrested two weeks later and, while awaiting trial, engaged in highly publicized lecture tours and, in March 1873, tried to vote again in city elections. She was thereafter tried and convicted of violating the voting laws but successfully refused to pay the fine. From then on she campaigned tirelessly for a federal woman suffrage amendment through the National Woman Suffrage Association (1869–90) and the National American Woman Suffrage Association (1890–1906) and by lecturing throughout the country and in the western territories.

With her close associates Stanton and Matilda Joslyn Gage she compiled and published *The History of Woman Suffrage*, 4 vol. (1881–1902). In 1888 she organized the International Council of Women and in 1904 the International Woman Suffrage Alliance. At meetings in London (1899) and Berlin (1904) she was acclaimed worldwide for her pioneer contribution to women's rights.

Anthony Lagoon, settlement, east-central Northern Territory, Australia, on the Barkly Tableland. Named for a permanent water hole in the course of Creswell Creek, sighted in 1879 by Ernest Favenc, it became an important watering point on a cattle-driving route from Western Australia to Queensland. Anthony Lagoon has an airfield and is an important station on the highway that carries linked cattle trucks to Alroy Downs, Brunette Downs, and eventually to the Barkly Highway. The settlement has been set aside as a historical site.

anthophyllite, an amphibole mineral, a magnesium and iron silicate that occurs in altered rocks, such as the crystalline schists of Kongsberg, Nor., southern Greenland, and Pennsylvania. Anthophyllite is commonly produced by regional metamorphism of ultrabasic rocks. Because its fibres have a low tensile strength, anthophyllite asbestos is not as important as crocidolite or amosite and much less so than chrysotile. For chemical formula and detailed physical properties, see amphibole (table).

Anthophyta (botany): see Magnoliophyta.

anthracene, a tricyclic aromatic hydrocarbon found in coal tar and used as a starting material for the manufacture of dyestuffs and in

scintillation counters. Crude anthracene crystallizes from a high-boiling coal-tar fraction. It is purified by recrystallization and sublimation. Oxidation yields anthraquinone (*q.v.*), an intermediate in the production of dyes and pigments. Pure anthracene crystallizes in colourless monoclinic plates, which show a blue fluorescence.

anthracite, also called **HARD COAL**, most highly metamorphosed variety of coal. It contains more fixed carbon (about 90 to 98 percent) than any other form of coal and the lowest amount of volatile matter (less than 8 percent), giving it the greatest calorific, or heat, value. Because of this, anthracite is the most valuable of the coals. It is, however, also the least plentiful. Anthracite makes up less than 2 percent of all coal reserves in the United States. Most of the known deposits occur in the eastern part of the United States.

Anthracites are black and have a brilliant, almost metallic lustre. They can be polished and used for decorative purposes. Hard and brittle, anthracites break with conchoidal fractures into sharp fragments that are clean to the touch. Although anthracites are difficult to ignite, they burn with a pale-blue flame and require little attention to sustain combustion. They are particularly adaptable for domestic use because they produce little dust upon handling and burn slowly while emitting relatively little smoke. They are sometimes mixed with bituminous coal for heating factories and other commercial buildings to reduce the amount of smoke produced but are seldom used alone for this purpose because of their high cost.

anthracnose, plant disease of warm humid areas that infects a variety of plants from trees to grasses. It is caused by certain fungi (usually *Colletotrichum* or *Gloeosporium*) producing spores in tiny, sunken, saucer-shaped fruiting bodies (acervuli). Symptoms include sunken spots of various colours in leaves, stems, fruits, or flowers. The spots often enlarge, leading to wilting, withering, and dying of tissues.

In the late 1970s a new form of the disease, dogwood anthracnose, was identified in North America. Unlike other forms of anthracnose, it thrives in cool climates. Dogwood anthracnose first appeared in the Pacific Northwest, and it soon spread to the eastern United States, eventually resulting in severe losses to natural stands of dogwoods in mountainous regions. The causative agent is *Discula destructiva*.

Anthracnose can be avoided by destroying diseased parts, using disease-free seed and disease-resistant varieties, applying fungicides, and controlling insects and mites that spread anthracnose fungi from plant to plant.

anthracosis, respiratory disorder, the early, usually nonsymptomatic stage of coal-workers' pneumoconiosis. See black lung.

anthraquinone, also called 9,10-ANTHRAQUINONE, the most important quinone derivative of anthracene and the parent substance of a large class of dyes and pigments. It is prepared commercially by oxidation of anthracene or condensation of benzene and phthalic anhydride, followed by dehydration of the condensation product.

Anthraquinone

Alizarin and many other vegetable pigments have chemical structures similar to anthraquinone. Anthraquinone can be converted to alizarin and to a number of synthetic dyestuffs, including a large family of vat dyes.

Although extremely stable toward oxidation, anthraquinone can be easily reduced to a variety of products. In alkaline solution, sodium dithionite reduces it to anthrahydroquinone, the alkali metal salts of which are water-soluble. The use of anthraquinones as vat dyes depends on this chemical reaction.

anthraquinone dye, any of a group of organic dyes having molecular structures based upon that of anthraquinone. The group is subdivided according to the methods best suited to their application to various fibres.

Anthraquinone acid dyes contain sulfonic acid groups that render them soluble in water and substantive for wool and silk; that is, they have an affinity for these fibres without the aid of auxiliary binding agents (mordants).

Anthraquinone disperse dyes lack the water-solubilizing groups of the acid dyes, but they are adsorbed by hydrophobic fibres such as nylon or acetate rayon with the aid of soap or other agents that keep the dye suspended in the application bath.

In several mordant dyes, the anthraquinone structure contains hydroxyl groups that participate in binding the dye to fibres such as cotton, wool, or silk that have been previously impregnated with the oxide of a metal such as aluminum, iron, tin, or chromium.

The anthraquinone vat dyes, valued for their brilliant colours and fastness to light and washing, are insoluble in water but become soluble upon treatment with a reducing agent, usually sodium hydrosulfite. The soluble vat or leuco form is adsorbed by the fibre and is then converted back to the insoluble form.

anthrax, also called **MALIGNANT PUSTULE** or **WOOLSORTER'S DISEASE**, acute, infectious disease of animals and humans caused by *Bacillus anthracis*, a bacterium that under certain conditions forms highly resistant spores capable of persisting and retaining their virulence for many years. Although anthrax most commonly affects grazing animals such as cattle and sheep, humans can develop the disease by eating the meat of or handling the wool, hair, hides, bones, or carcasses of affected animals.

Anthrax in humans occurs as a cutaneous, pulmonary, or intestinal infection. The most common type, cutaneous anthrax, usually results from handling infected material. Lesions occur mostly on the hands, arms, or neck. A lesion begins as a small pimple that develops rapidly into a large vesicle with a black necrotic centre (the malignant pustule). Should this condition become generalized, a fatal septicemia (blood poisoning) may ensue. The pulmonary form, called inhalation anthrax (wool sorter's disease), affects principally the lungs and results from inhaling anthrax spores (*e.g.*, in areas where hair and wool are processed). This form of the disease usually runs a rapid course and terminates fatally. The intestinal form of the disease, which sometimes follows the consumption of contaminated meat, is characterized by an acute inflammation of the intestinal tract, vomiting, and severe diarrhea. In all forms of anthrax, prompt diagnosis and early treatment are of great importance. Anti-anthrax serum, arsenicals, and antibiotics (*e.g.*, ciprofloxacin; *q.v.*) are used with excellent results. The hazard of infection to agricultural and industrial workers can be reduced by avoiding skinning or opening of diseased animals, by sterilization of potentially contaminated material before handling, and by the use of protective clothing and respirators.

In animals, the acute forms are marked by a rise in body temperature followed by spasms, respiratory or cardiac distress, trembling, staggering, and convulsions. Bloody discharges sometimes come from the natural body openings, and edematous (serous fluid) swellings

may appear on different parts of the body. Death usually occurs within a day or two. Chronic anthrax occurs mostly in swine and dogs and is characterized by swelling of the throat, difficult breathing, and a bloodstained frothy discharge from the mouth. Affected animals sometimes die of suffocation. Prophylactic vaccination is extensively used in preventing anthrax in livestock. During outbreaks, strict quarantine measures, disposal of diseased carcasses by burning, and good sanitation are essential in controlling the disease.

Anthrax is one of the oldest recorded diseases, being mentioned by Moses in Exodus 9:9 and among the classical authors of Greek and Roman antiquity. In the 16th to 18th centuries it sometimes spread across the southern part of Europe, taking a heavy toll of human and animal life. Anthrax was the first disease in which the causative agent was definitely demonstrated as a specific microorganism—by French biologist Casimir-Joseph Davaine in 1863 and in 1876 by German bacteriologist Robert Koch, who isolated the organism in pure culture. It was also the first infectious disease against which a bacterial vaccine was found to be effective, by French chemist and microbiologist Louis Pasteur in 1881.

The bacterium that causes anthrax has a number of attributes that, in combination, make it suitable as a biological weapon. In addition to being widely available—located around the world in soil and in diseased animals and their remains—*B. anthracis* spores are small enough to lodge readily in the lungs of humans. The anthrax bacterium has a short incubation period and is highly lethal, requiring only a small amount to cause a mass casualty effect. Indeed, aerosolized forms of anthrax sprayed over a large population centre or massed military force are capable of lethality approaching or exceeding that of a nuclear weapon. Moreover, anthrax can be produced inexpensively, in larger quantities than can other biological warfare agents, and in facilities that are relatively easy to hide. It is more resilient to degradation from ultraviolet light than most other biological agents. Finally, anthrax can be converted into either a powder or a liquid, allowing it to be used in a number of types of weapons systems utilizing a variety of delivery means, including missiles, artillery, mortars, or crop-duster-type aircraft.

Anthrax has been weaponized by a number of states. Before it terminated its offensive biological weapons program in 1969, the United States had a significant anthrax weapons program. The former Soviet Union developed the world's largest biological weapons program, which it clandestinely continued 20 years beyond the date when it signed the Biological Weapons Convention of 1972, which prohibited the development and stockpiling of biological weapons. Iraq, under the rule of Saddam Hussein, also obtained anthrax but claimed to have destroyed biological weapons after the Persian Gulf War of 1990–91. At least 14 other nations are believed to have biological weapons programs.

Terrorists have used anthrax in an attempt to kill and frighten victims in both Japan and the United States. The AUM Shinrikyo religious sect released anthrax in Tokyo on three separate occasions in 1993, targeting downtown crowds and members of the Japanese legislature. In 2001 a number of anthrax-laced letters were sent through the mail to the offices of two United States senators and various media headquarters in New York and Florida, killing five people along their routes and infecting 17 others.

Several effective vaccines have been developed to protect against possible anthrax infection, including Anthrax Vaccine Adsorbed

(AVA), a vaccine developed to protect United States military personnel. The anthrax vaccine can provide protection to most recipients. However, if vaccinated military personnel were to encounter a massive dose of anthrax, such as might be encountered on a battlefield, even a sensitized immune system can be overwhelmed; a well-fitting mask with fine-grain filters is necessary to provide protection in such instances.

Anthropoidea, suborder of primates including the families Callitrichidae (marmoset, *q.v.*), Cebidae (*q.v.*; New World monkeys), Cereopithecidae (*q.v.*; Old World monkeys), Hylobatidae (gibbon and siamang, *qq.v.*), Pongidae (gorilla, chimpanzee, and orangutan, *qq.v.*), Hominidae (humans and fossil relatives), and the fossil group Parapithecidae.

anthropological linguistics, study of the relationship between language and culture; it usually refers to work on languages that have no written records. In the United States a close relationship between anthropology and linguistics developed as a result of research by anthropologists into the American Indian cultures and languages. Early students in this field discovered what they felt to be significant relationships between the languages, thought, and cultures of the Indian groups. The issue of the relatedness of language and culture is still a controversial one, and it is now thought by many scholars that the relationship is not as close as was first suspected. Anthropologists currently draw on linguistic techniques primarily for the analysis of such areas as kinship systems, botanical taxonomies, and colour terms, but a number of anthropologists are still engaged in fieldwork centring on language description.

anthropology, the study of human beings, in particular the study of their physical character, evolutionary history, racial classification, historical and present-day geographic distribution, group relationships, and cultural history. Anthropology can be characterized as the naturalistic description and interpretation of the diverse peoples of the world.

Modern-day anthropology consists of two major divisions: cultural anthropology, which deals with the study of human culture in all its aspects; and physical anthropology, which is the study of human physical character, in both the past and present. *See* cultural anthropology; physical anthropology.

anthropometry, the systematic collection and correlation of measurements of the human body. Now one of the principal techniques of physical anthropology, the discipline originated in the 19th century, when early studies of human biological and cultural evolution stimulated an interest in the systematic description of populations both living and extinct. In the latter part of the 19th century, anthropometric data were applied, often subjectively, by social scientists attempting to support theories associating biological race with levels of cultural and intellectual development. The Italian psychiatrist and sociologist Cesare Lombroso, seeking physical evidence of the so-called criminal type, used the methods of anthropometry to examine and categorize prison inmates.

The simplest anthropometric measurements included the ratio of the breadth to the length of the skull (the "cephalic index"), that of the width to the length of the nose, the proportion of the upper arm to the lower arm, and so on. These measurements could be made with such familiar pieces of equipment as metersticks, calipers, and measuring tapes. By selecting reliable measuring points, or "landmarks," on the body, and standardizing the measuring techniques used, measurements could be made with great accuracy. The masses of data acquired from such investigations were used

by physical anthropologists in the 19th and early 20th centuries to try to characterize various racial, ethnic, and national groups in terms of those bodily features peculiar to or typical of them.

In the 20th century, the application of anthropometry to the study of racial types was replaced by more sophisticated techniques for evaluating racial differences. Anthropometry continued to be a valuable technique, however, gaining an important role in paleoanthropology, the study of human origins and evolution through fossil remains. Craniometry, the measurement of the skull and facial structure, also a development of the 19th century, assumed new importance with the discoveries in the 1970s and '80s of human and prehuman fossils greatly predating any such previous finds. Craniometric studies of prehistoric skull and face bones have enabled anthropologists to trace the gradual changes that occurred in the size and shape of the human head as it enlarged to accommodate increased brain volume; as a result, craniometry and other anthropometric techniques led to a major reevaluation of prevailing theories that the adoption of an erect posture and the enlargement of the brain occurred simultaneously in human development.

In addition to its scholarly functions, anthropometry also has commercial applications. Anthropometric data have been used by industrial researchers in the design of clothing, especially military uniforms, and in the engineering of, for example, automobile seats, airplane cockpits, and space capsules.

anthropomorphism, the attribution of human form or other human characteristics to any nonhuman object. In religion, the term is applied to any statement that depicts the deity as having a bodily form resembling that of human beings, or as possessing qualities of thought, will, or emotion that are continuous with those experienced by humans. Any reference to the divine as having a human body or a part of a human body is an anthropomorphism—*e.g.*, the hand of God, the eye of God, or the mouth of God. References to human-like mental aspects are also regarded as anthropomorphisms—*e.g.*, the will of God, the mind of God, the compassion of God, and even the love of God. The word anthropomorphism means literally "in the form of man" (derived from the Greek words *anthrōpos*, "man," and *morphē*, "form").

Perhaps the best-known anthropomorphisms in religion are those of the ancient Greeks and Romans, whose gods resembled humans in almost everything except their immortality, their places of residence, and their magical powers over nature. Xenophanes (6th–5th century BC) attacked the anthropomorphism of Homer and Hesiod in ascribing "to the gods all deeds that are a shame and a disgrace among men: thieving, adultery, fraud." Similarly, Plato repudiated the crass anthropomorphism of traditional Homeric mythology and instead asserted the idea, in accord with Xenophanes, that God is one, and beyond human powers of comprehension.

The classical Hebrew prophets, such as Amos and Isaiah, were vigorous critics of the gross anthropomorphism among the Hebrews of their day, reminding their listeners, for example, that the moral judgments of God were not based upon the tribal preferences that influence human judgment. The prophets did not entirely abandon anthropomorphism, however, but freely employed refined anthropomorphic symbols as indispensable to their concept of God as personal. The author of the Book of Ecclesiastes carried the critique of anthropomorphism further, approaching the idea of an impersonal cosmic force in place of the Hebraic personal God. It must be noted, however, that while many of the anthropomorphisms in the Old Testament were

undoubtedly taken literally by their authors, many more are recognized and intended merely as poetic metaphors. Thus, there is a difference between the intention of the relatively early statement that "the Lord used to speak to Moses face to face, as a man speaks to his friend" (Exodus 33:11) and that of the consciously poetic question directed by the Psalmist to God: "How long wilt thou hide thy face from me?" (Psalms 13:1).

While many thinkers have believed it possible to purge theism (belief in the existence of God) of all traces of anthropomorphism, many others have regarded the latter as essential to theistic knowledge and language.

anthropophagy: see cannibalism.

anthroposophy, philosophy based on the premise that the human intellect has the ability to contact spiritual worlds. It was formulated by Rudolf Steiner (*q.v.*), an Austrian philosopher, scientist, and artist, who claimed that an enhanced consciousness can perceive spiritual worlds and who attempted to develop a faculty for spiritual perception independent of the senses. He founded the Anthroposophical Society in 1912. The society, now based in Dornach, Switz., has branches worldwide.

Anthurium, genus of tropical American herbaceous plants, comprising about 600 species in the arum family (Araceae), many of which are popular foliage plants. A few species are widely grown for the florist trade for their showy, long-lasting blossoms, which consist of colourful leathery, shiny spathes surrounding or subtending a central rodlike spadix that bears numerous tiny bisexual flowers. Because anthuriums require warm temperatures and high humidity, they are usually grown under greenhouse conditions.

anti-: see below and see also unhyphenated words with this prefix.

Anti-Atlas, also called LESSER ATLAS, mountain range in Morocco running parallel to and southward of the central range of the Atlas Mountains of North Africa. It has a mean elevation of 5,000 feet (1,500 m), but some peaks and passes exceed 6,000 feet (1,800 m). This rugged region encloses the Sous lowland, reaches the Atlantic coast at Sidi Ifni, and is linked to the Haut (High) Atlas by Mount Siroua, a volcanic peak rising to 10,840 feet (3,304 m).

Anti-Comintern Pact, agreement concluded first between Germany and Japan (Nov. 25, 1936) and then between Italy, Germany, and Japan (Nov. 6, 1937), ostensibly directed against the Communist International (Comintern) but, by implication, specifically against the Soviet Union.

The treaties were sought by Adolf Hitler, who at the time was publicly inveighing against Bolshevism and who was interested in Japan's successes in the opening war against China. The Japanese were angered by a Soviet-Chinese nonaggression treaty of August 1936 and by the subsequent sale of Soviet military aircraft and munitions to China.

On Aug. 23, 1939, Japan, outraged by the German-Soviet Nonaggression Pact, renounced the Anti-Comintern Pact but later acceded to the Tripartite Pact (Sept. 27, 1940), which pledged Germany, Italy, and Japan "to assist one another with all political, economic and military means" when any one of them was attacked by "a Power at present not involved in the European War or in the Sino-Japanese Conflict" (*i.e.*, the Soviet Union or the United States).

Anti-Fascist Council for the National Liberation of Yugoslavia, Serbo-Croatian ANTI-FAŠISTIČKO VEĆE NARODNOG OSLOBOĐENJA JUGOSLAVIJE (AVNOJ), umbrella organization established during World War II by the Communist Party of Yugoslavia to coordinate the military campaigns of Josip Broz Tito's

Partisans and the administrative activities of local "liberation committees."

AVNOJ was first convened at the Bosnian town of Bihać (Nov. 26–27, 1942). The participation of noncommunists allowed a National Liberation Movement to be announced that called upon all nationalities within Yugoslavia to join the struggle to liberate the country from Axis occupation. This broad appeal won support for the Partisans from a populace grown weary of ethnic hatreds. At its second session, at Jajce (Nov. 29–30, 1943), AVNOJ assumed greater legislative and executive functions and elected a central National Liberation Committee, which became virtually a provisional government. Tito was proclaimed marshal of Yugoslavia, and a plan was adopted for a postwar reorganization of the kingdom into a federation of six equal republics. After its third session, which was convened at Belgrade (Aug. 7–10, 1945) after liberation, AVNOJ yielded its authority to a Constituent Assembly, which, dominated by communists, met in November 1945 to draft a Soviet-style constitution for the new Federal People's Republic of Yugoslavia.

Anti-Federalists, a coalition of U.S. politicians who opposed the strong central government envisioned in the U.S. Constitution of 1787 and whose agitations led to the Bill of Rights. The first states'-rights advocates, they feared the authority of a single national government, inadequate separation of powers, and loss of control over local affairs. Stilling their opposition in order to support the first administration of President George Washington, the Anti-Federalists in 1791 became the nucleus of the Jeffersonian Republican Party (subsequently Democratic-Republican, finally Democratic) as strict constructionists of the Constitution and as opponents of a strong national fiscal policy.

Anti-Lebanon Mountains, Arabic AL-JABAL ASH-SHARQĪ, or LUBNĀN ASH-SHARQĪ, French ANTI-LIBAN, mountain range that runs north-east-southwest along the Syrian-Lebanese border parallel to the Lebanon Mountains, from which they are separated by the al-Biqā' Valley. The range averages 6,500 feet (2,000 m) above sea level, with peaks exceeding 8,000 feet (2,400 m). As it runs south, the Anti-Lebanon range is interrupted by a broad shoulder (the Zabadani Saddle) of Mount Hermon, 9,232 feet (2,814 m) high, which is sometimes considered the southernmost extension of the range. Because of thin soils, limestone sinks, steep slopes, and aridity, the Anti-Lebanon range is sparsely populated and economically useful only for nomadic herding.

Anti-Masonic Movement, 19th-century U.S. movement against the secret fraternal order of the Masons, or Freemasons, which led to the birth of the Anti-Masonic Party. It was the first American third party, the first party to hold a national nominating convention, and the first to offer an electoral platform.

The movement began in 1826 with the disappearance of William Morgan, a bricklayer in New York who supposedly broke his vow of secrecy as a Freemason. When no trace of Morgan could be discovered, rumours of his murder by Masons spread rapidly.

Anti-Masonic candidates won state and local elections, and Anti-Masonic newspapers flourished. In 1831 the Anti-Masonic Party held a national convention in Baltimore, Md., nominated William Wirt for president, and passed a platform condemning Masonry.

Wirt won only Vermont in the 1832 election, and the party declined after that. By the late 1830s its reform impulse had been absorbed by antislavery agitation, and its politicians had joined the new Whig Party.

Anti-Saloon League, group that promoted prohibition (*q.v.*) in the United States. It formed in Ohio in 1893 and became a nation-

al organization in 1895. Supported by evangelical churches, it sought legislation against the manufacture and sale of alcohol. After passage of the Eighteenth (Prohibition) Amendment in 1919, the league worked for enforcement of the law. The amendment's repeal in 1933 ended the group's political power, and in 1950 it formed the National Temperance League with other groups.

anti-Semitism, hostility toward or discrimination against Jews as a group. *Anti-Semitism* was coined in 1879 by the German agitator Wilhelm Marr to designate contemporary anti-Jewish campaigns in Germany. The term has wide currency but is a misnomer, since it implies discrimination against all Semites, a group that includes Arabs and others who are not targets of anti-Semitism as it is usually understood. Nazi anti-Semitism was racist, targeting Jews because of their supposed biological characteristics—even those who had converted to other religions or whose parents were converts. Anti-Jewish racism dates to the "scientific racism" of the 19th century and differs from earlier anti-Jewish prejudices.

The origins of Christian anti-Semitism. Although Jesus was a Jew, and Christianity is rooted in Jewish monotheism, Judaism and Christianity became rivals after the Roman destruction of the Temple of Jerusalem in 70 CE. Following this event, which was interpreted by Jew and Christian as divine punishment, the Gospels diminished Roman responsibility and expressed Jewish culpability in Jesus' death.

Christianity sought to replace Judaism. The New Testament was seen as fulfilling the "Old" Testament (the Hebrew Bible); Christians were the new Israel. Thus some early Church Fathers taught that God had finished with the Jews, whose purpose in history was to prepare for the arrival of his son. Their survival seemed to be an act of stubborn defiance. Exile was taken as a sign of divine disfavour incurred by the Jews' denial that Jesus was the Messiah and by their role in his crucifixion.

From St. Augustine in the 4th century to Martin Luther in the 16th, Christian theologians execrated the Jews as rebels against God and murderers of the Lord. They were described as companions of the devil and a race of vipers. Church liturgy, particularly that of the Good Friday commemoration of the Crucifixion, reinforced the theologians' enmity.

The Roman Catholic church renounced these views only after the Holocaust, with the Vatican II declaration of *Nostra aetate* (Latin: "In Our Era") in 1965, which revamped Catholic teaching regarding Jews and Judaism. The Vatican accepted the legitimacy of Judaism as a continuing religion and exonerated Jews for the crucifixion of Jesus by universalizing responsibility for it. As a result, the Good Friday liturgy was made less inflammatory with regard to Jews. A centrepiece of the papacy of John Paul II, who witnessed the Holocaust in Poland, was his embrace of Jews and fight against anti-Semitism. He paid a historic visit to a synagogue in Rome in 1986, recognized the State of Israel in 1993, and declared anti-Semitism anti-Christian at Yad Vashem, Israel's Holocaust memorial, and inserted an apology for Christian misdeeds into the Western Wall during his trip to Israel in 2000.

Anti-Semitism in medieval Europe. In much of Europe during the Middle Ages, Jews were denied citizenship, barred from holding civil and military posts, and excluded from membership in guilds and the professions. Yet some European rulers and societies afforded Jews a degree of tolerance and acceptance, and it would be an error to conceive of Jews facing unceasing anti-Jewish oppression throughout this period. In the 1090s, however, knights of the First Crusade unleashed a wave of anti-Se-

mitic violence in France and the Holy Roman Empire, including massacres in Worms, Trier (both now in Germany), and Metz (now in France). Unfounded accusations of ritual murder, host desecration, and the blood libel—Jews' alleged sacrifice of Christian children at Passover to obtain blood for unleavened bread—appeared by the 12th century, and the latter became part of Nazi propaganda. Another tool of 12th-century anti-Semitism, the compulsory yellow badge that identified the wearer as a Jew, was also revived by the Nazis. The medieval practice of segregating the Jews into ghettos lasted until the early 20th century in much of Europe.

As commerce grew in the Middle Ages, some Jews became prominent in trade, banking, and moneylending, and Jews' economic and cultural successes aroused the envy of others. This resentment, allied with traditional religious prejudice, facilitated the expulsion of Jews from England (1290), France (14th century), Germany (1350s), Portugal (1496), Provence (1512), and the Papal States (1569). Persecution in Spain culminated in 1492 in the expulsion of that country's large and long-established Jewish population. As a result of these expulsions, the centres of Jewish life shifted from western Europe and Germany to Turkey and then to Poland and Russia.

But where they were needed, Jews were tolerated. Where they could participate in the larger society, Jews thrived. In medieval Spain, before their expulsion, Jewish philosophers, physicians, poets, and writers were among the leaders of a rich cultural life shared with Muslims and Christians. Jewish and Muslim scholars in Islāmic Spain were instrumental in transmitting the cultural heritage of the classical world to medieval Christendom.

The idea that the Jews were evil persisted in the Protestant Reformation and was virulently expressed by Luther. "We are at fault for not slaying them," he wrote. "Rather we allow them to live freely in our midst despite their murder, cursing, blaspheming, lying and defaming." The Nazis emphasized such views, which were renounced by Lutherans in the late 20th century.

Anti-Semitism in modern Europe. The end of the Middle Ages brought little change in the Jews' position in Europe, and the Catholic Reformation renewed anti-Jewish legislation and reinforced the system of ghetto segregation in Roman Catholic countries. Persecutions of European Jews continued until the Enlightenment, which changed their position in society but did not necessarily reduce anti-Semitism. Enlightenment thinkers debunked what they regarded as the superstitions of Christian belief, but their appeal to reason did not lead to any greater acceptance of Jews. Indeed, some, including Denis Diderot and Voltaire, pilloried the Jews as a group alienated from society who practiced a superstitious religion.

Until the French Revolution of 1789, European Jews were treated as outsiders with few civil rights, and this exclusion reinforced their religious identity and communal institutions. In the French Revolution, citizenship rights were extended to Jews on the condition that they abandon their customs and communal identity.

France led the movement to give civic and legal equality to the Jews. Napoleon's conquest of the German states led to emancipation in some of them, but after his defeat, Jews faced a series of legal setbacks. Full emancipation of Jews throughout Germany came only with its unification in 1871.

Even in France, emancipation merely transformed anti-Semitism. With the emergence of nationalism in the 19th century, anti-Semitism acquired a racial rather than a religious character as ethnically homogeneous peoples

decried "alien" Jewish elements in their midst. Pseudoscientific theories asserting that the Jews were inferior to the so-called Aryan "race" gave anti-Semitism new respectability, especially in countries where Jews could be made scapegoats for existing social ills. In France in 1894 Alfred Dreyfus, a Jewish army officer, was falsely accused of treason. His final vindication (in 1906) was hampered by the French military, still bitter over the defeat by Germany in 1870. Anti-Semitism also became a powerful political tool. In Germany and Austria, anti-Semitism became a movement with its own political parties.

The Russian Empire had restricted Jews to western regions known as the Pale of Settlement ever since the final partitions of Poland (in the 1790s) had brought large numbers of Jews under Russian rule. The empire's May Laws of 1882, enacted after widespread anti-Jewish riots, or pogroms, had broken out in the Russian Pale the previous year, stripped Jews of their rural landholdings and restricted them to the towns and cities within the Pale. These measures, which crippled many Jews' activities as rural traders and artisans, spurred the emigration of more than a million Jews to the United States over the next four decades. In 1903 and 1905 serious pogroms occurred in Kishinyov (now Chişinău, Moldova), and the Russian secret police published a forgery entitled *Protocols of the Learned Elders of Zion*, the supposed blueprint for a Jewish plot to gain world domination, that furnished propaganda for generations of anti-Semitic agitators.

The economic and political dislocations caused by World War I intensified postwar anti-Semitism in Europe. The many Jewish Bolshevik leaders in the Russian Revolution of November 1917 also gave anti-Semites a new focus for their prejudices in the threat of "Jewish Bolshevism." In postwar Germany, anti-Semites and revanchist nationalists blamed the Jews for that country's defeat. Anti-Semitism also was widespread in Poland, Hungary, and Romania in the interwar period.

Nazi anti-Semitism and the Holocaust. The storm of anti-Semitic violence loosed by Nazi Germany under the leadership of Adolf Hitler from 1933 to 1945 not only reached a terrifying degree in Germany itself but also inspired anti-Jewish movements in France, Hungary, England, and the United States.

In Nazi Germany, anti-Semitism reached a new level. If Christianity sought the conversion of the Jews, and political leaders from Spain to England sought their expulsion, the Nazis sought the "final solution to the Jewish question," the killing of all Jews and their eradication from the human race. In Nazi ideology the elimination of the Jews was essential to the purification and even the salvation of the German people. Anti-Semitism and ideas of racial superiority became government policy—taught in the schools, elaborated in "scientific" journals and research institutes, and promoted by a highly effective organization for international propaganda. In 1941 the liquidation of European Jewry became official Nazi party policy. Some 5,700,000 Jews were exterminated in such death camps as Auschwitz and Treblinka during World War II.

Anti-Semitism since the Holocaust. Although anti-Semitism lost favour in western Europe and the United States after the Nazi defeat in 1945, it persisted in many countries. In the Soviet Union, opposition to the State of Israel and to the attempts of Soviet Jews to emigrate was linked to historic Russian anti-Semitism. In post-Soviet Russia, opposition to the regime or to the number of Jews among the oligarchy has had anti-Semitic overtones. Foreign concern over Kurt Waldheim's Nazi past provoked anti-Semitic reactions among his supporters during his successful 1986 campaign for the Austrian presidency. During the late 1990s, when it was revealed that Swiss banks had laundered Nazi gold (much of it

likely confiscated from Jews) during World War II and had failed to return money to Jewish depositors after the war, international criticism and demands for restitution provoked increased anti-Semitism in Switzerland. In several European countries, nativistic parties opposed to immigration and the European Union engaged in anti-Semitic speech or actions. Even countries with few Jewish residents have manifested anti-Semitism. For example, the discredited *Protocols of the Learned Elders of Zion* was popular in Japan in the 1980s and '90s.

Islāmic societies had long tolerated Jews but made them pay special taxes, wear identifying clothing, and live in specified areas. But the emigration of large numbers of Jews to Palestine in the 20th century and the creation of the State of Israel (1948) in a formerly Arab region inspired hostility in the Arab world that has been political (or anti-Zionist) and religious rather than racial. Whatever the motivation, many anti-Jewish measures were adopted throughout the Islāmic Middle East. In response, most Jewish residents of those countries emigrated to Israel after its founding.

(Mi.Be.)

antacid: see antacid.

antiaircraft gun, artillery piece that is fired from the ground or shipboard in defense against aerial attack. Antiaircraft weapons development began as early as 1910, when the airplane first became an effective weapon. In World War I, field artillery pieces up to about 90 mm (3.5 inches) in calibre were converted to antiaircraft use by mountings that enabled them to fire nearly vertically. Aiming methods were inadequate, however, and in the interwar decades progress was made in developing range finders, searchlights, time fuzes, and gunlaying mechanisms to help artillery pieces hit the rapidly moving targets presented by aircraft.

In World War II, rapid-firing and automatic antiaircraft guns appeared, radar was applied to target tracking, and tiny radio-wave proximity fuzes exploded the ammunition as it approached the target. Against dive-bombers and low-level attack aircraft, a 40-mm (1.5-inch) gun, produced by the Bofors firm of Sweden, was used by British and U.S. forces. It fired 2-pound (0.9-kg) projectiles to a height of 2 miles (3.2 km) at 120 rounds per minute. The Soviets based their 37-mm weapon on this gun. Heavier antiaircraft guns, up to 120 mm, were used against high-flying bombers. The most effective of these was the German 88-mm *Fliegerabwehrkanone*, or flak, which became a universal term for antiaircraft fire.

In 1953 the U.S. Army introduced the Skysweeper, a 75-mm automatic cannon firing 45 shells per minute, aimed and fired by its own radar-computer system. With the introduction of guided surface-to-air missiles in the 1950s and '60s, heavy antiaircraft guns such as this were phased out, though radar-guided automatic guns of 20 to 40 mm continued to provide a defense against low-flying aircraft and helicopters.

antiarch, any of an order of extinct, mainly freshwater, jawed fishes, class Placodermi, abundant during Middle and Late Devonian times (387 to 360 million years ago). Members of such genera as *Bothriolepis* and *Pterichthys* were representative. Antiarchs were small and weak-jawed and had closely set eyes on top of the head. Armour shields covered the front part of the body, and armoured, jointed appendages extended from the shoulder regions. The hind part of the body was naked in *Bothriolepis* and covered with scales in *Pterichthys*.

Antiarchs may have been bottom dwellers that fed upon small animals and on plants and pulled themselves about with the pectoral appendages. The presence of paired sacs in these primitive fishes suggests that lungs were evolved earlier than was once thought.

Antibes, port town, Alpes-Maritimes *département*, Provence-Alpes-Côte-d'Azur *région*, France, on the eastern side of the Garoupe Peninsula across the Baie des Anges (Bay of the Angels) from Nice. Originally Antipolis, a Greek trading post established by Phocaeans from Marseille, it became a Roman town and eventually a fief of the coast-ruling Grimaldi family from 1384 to 1608. The Grimaldi château, much rebuilt over the ages, is now a museum featuring works of Pablo Picasso, who painted there in 1946. There is also an archaeological museum displaying the Grimaldi fossils, remains of prehistoric man discovered locally. Juan-les-Pins, with its parasol pines

they are produced by the mold *Cephalosporium acremonium*. A class of antibiotics first developed in the 1960s, called quinolones, interrupt the replication of DNA (a crucial step in bacterial reproduction) and have proved useful in treating urinary-tract infections, infectious diarrhoea, and various other infections involving such elements as bones and white blood cells. Antibiotics can treat many bacterial and, to a lesser extent, fungal infections but not viral infections.

The principle governing the use of antibiotics is to ensure that the patient receives one to which the target bacterium is sensitive, at a high enough concentration to be effective (but

cells. When an antigen binds to the B-cell surface, it stimulates the B cell to divide and mature into a group of identical cells called a clone. The mature B cells, called plasma cells, secrete millions of antibodies into the bloodstream and lymphatic system.

As antibodies circulate, they attack and neutralize antigens that are identical to the one that triggered the immune response. Antibodies attack antigens by binding to them. The binding of an antibody to a toxin, for example, can neutralize the poison simply by changing its chemical composition; such antibodies are called antitoxins. By attaching themselves to some invading microbes, other antibodies can render such microorganisms immobile or prevent them from penetrating body cells. In other cases the antibody-coated antigen is subject to a chemical chain reaction with complement, which is a series of proteins found in the blood. The complement reaction either can trigger the lysis (bursting) of the invading microbe or can attract microbe-killing scavenger cells that ingest, or phagocytose, the invader. Once begun, antibody production continues for several days until all antigen molecules are removed. Antibodies remain in circulation for several months, providing extended immunity against that particular antigen.

B cells and antibodies together provide one of the most important functions of immunity, which is to recognize an invading antigen and to produce a tremendous number of protective proteins that scour the body to remove all traces of that antigen. Collectively all B cells recognize an almost limitless number of antigens; however, individually each B cell can bind to only one type of antigen. B cells distinguish antigens through proteins, called antigen receptors, found on their surfaces. An antigen receptor is basically an antibody protein that is not secreted but is anchored to the B-cell membrane.

Each antibody molecule is essentially identical to the antigen receptor of the B cell that produced it. The basic structure of these proteins consists of two pairs of polypeptide chains (lengths of amino acids linked by peptide bonds) that form a flexible Y-shape. The stem of the Y consists of one end of each of two identical heavy chains, while each arm is composed of the remaining portion of a heavy chain plus a smaller protein called a light chain. The two light chains also are identical. Within particular classes of antibodies the stem and the bottom of the arms are fairly similar and thus are called the constant region. The tips of the arms, however, are highly variable in sequence. It is these tips that bind antigen. Thus each antibody has two identical antigen-binding sites, one at the end of each arm, and the antigen-binding sites vary greatly among antibodies.

Antibodies are grouped into five classes according to their constant region. Each class is designated by a letter attached to an abbreviation of the word "immunoglobulin": IgG, IgM, IgA, IgD, and IgE. The classes of antibody differ not only in their constant region but also in activity. For example, IgG, the most common antibody, is present mostly in the blood and tissue fluids, while IgA is found in the mucous membranes lining the respiratory and gastrointestinal tracts.

Preformed antibodies, which are derived from the blood serum of previously infected people or animals, are often administered in an antiserum to another person in order to provide immediate, passive immunization against fast-acting toxins or microbes, such as those in snakebites or tetanus infections.

anticholinesterase, any of several drugs that prevent destruction of the neurotransmitter acetylcholine by the enzyme acetyl-

The ramparts, old city, and port of Antibes, Fr.

Editions "La Cigogne"—Hachette

and sand beach, is part of the Antibes *commune*, which also includes the luxury resort of Cap d'Antibes. An important part of the economy, in addition to tourism, is the production of flowers, many under glass. Pop. (1999) 72,412.

antibiotic, chemical substance produced by a living organism, generally a microorganism, that is detrimental to other microorganisms.

A brief treatment of antibiotics follows. For full treatment, see MACROPAEDIA: Drugs and Drug Action: *Chemotherapy*.

Antibiotics are released naturally into the soil by bacteria and fungi, but did not come into worldwide prominence until the introduction of penicillin in 1941. Since then they have revolutionized the treatment of bacterial infections in humans and other animals.

In 1928 Alexander Fleming noticed that colonies of bacteria growing on a germ culture medium had been unfavourably affected by a mold, *Penicillium notatum*, which had contaminated the culture. A decade later Ernst Chain, Howard Florey, and others isolated the ingredient responsible, penicillin, and showed that it was highly effective against many serious bacterial infections. Toward the end of the 1950s scientists then added various chemical groupings to the core of the penicillin molecule to generate semisynthetic versions. A range of penicillins is thus now available to treat diseases caused by such bacteria as staphylococci, streptococci, pneumococci, gonococci, and the spirochaetes of syphilis.

Unaffected by penicillin is the tubercle bacillus, but this organism proved to be highly sensitive to streptomycin, isolated from *Streptomyces griseus* in 1943. As well as being dramatically effective against tuberculosis, streptomycin vanquishes many other bacteria, including the typhoid fever bacillus. Two other early discoveries were gramicidin and tyrocidin, made by bacteria of the genus *Bacillus*. Discovered in 1939 by René Dubos, they have proved to be valuable in treating surface infections but are too toxic for internal use. Other, more recently isolated, antibiotic drugs are the cephalosporins. Related to penicillins,

not cause side effects), and for a sufficient length of time to ensure that the infection is totally eradicated. Antibiotics vary in their range of action. Some are highly specific. Others, such as the tetracyclines, act against a broad spectrum of different bacteria. These are particularly useful in combating mixed infections and in treating infections when there is no time to conduct sensitivity tests. Some semisynthetic penicillins and the quinolones can be taken orally, but most antibiotics must be given by intramuscular injection.

A problem that has plagued antibiotic therapy from the earliest days is the resistance that bacteria can develop to the drugs. An antibiotic may kill virtually all the bacteria causing a disease in a patient, but a few bacteria that are genetically less vulnerable to the effects of the drug may survive. These go on to reproduce or to transfer their resistance to others of their species through processes of gene exchange. With their more vulnerable competitors wiped out or reduced in numbers by antibiotics, these resistant strains proliferate; the end result is bacterial infections in humans that are untreatable by one or even several of the antibiotics customarily effective in such cases. The indiscriminate and inexact use of antibiotics encourages the spread of such bacterial resistance.

antibody, a protective protein produced by the immune system in response to the presence of a foreign substance, called an antigen. Collectively antibodies are known as immunoglobulins. Antibodies recognize and latch onto antigens in order to remove them from the body. The body regards a wide range of substances as antigens, including disease-causing organisms and toxic materials such as insect venom.

When an alien substance enters the body, the immune system is able to recognize it as foreign because molecules on the surface of the antigen differ from those found in the body. To eliminate the invader, the immune system calls on a number of mechanisms, including one of the most important—antibody production. Antibodies are produced by specialized white blood cells called B lymphocytes or B

cholinesterase within the nervous system. Acetylcholine acts to transmit nerve impulses within the parasympathetic nervous system—*i.e.*, that part of the autonomic nervous system that contains chiefly cholinergic fibres and that tends to induce secretion, to contract smooth muscles, and to dilate blood vessels. In preventing the destruction of acetylcholine, anticholinesterase permits high levels of this neurotransmitter to build up at the sites of its action, thus stimulating the parasympathetic nervous system and in turn slowing the heart action, lowering blood pressure, increasing secretion, and inducing contraction of the smooth muscles.

Physostigmine and neostigmine are among the principal anticholinesterases. These drugs have only a few clinical uses, mainly in augmenting gastric and intestinal contractions (in treatment of obstructions of the digestive tract), in generally augmenting muscular contractions (in the treatment of myasthenia gravis), and in constricting the eye pupils (in the treatment of glaucoma). Other anticholinesterases in larger doses, however, are widely used as toxins that achieve their effects by causing a continual stimulation of the parasympathetic nervous system. Parathion and malathion are thus highly effective agricultural insecticides, while tabun and soman are nerve gases used in chemical warfare to induce nausea, vomiting, convulsions, and death in humans.

Antichrist, the chief enemy of Christ. The earliest mention of the name Antichrist, which was probably first coined in Christian eschatological literature (concerned with the end of time), is in the letters of St. John (I John 2:18, 22; II John 7), although the figure does appear in the earlier II Thessalonians as "the lawless one." Yet the conception of a mighty ruler who will appear at the end of time and whose essence will be enmity of God is older and was taken over by Christianity from Judaism.

Jewish eschatology had been influenced by Iranian and Babylonian myths of the battle of God and the devil at the end of time. In the Old Testament the Jewish conception of the struggle is found in the prophecy of Daniel, written at the beginning of the Maccabean period (c. 168 BC). The historical figure who served as a model for the Antichrist was Antiochus IV Epiphanes, the persecutor of the Jews, and he left a lasting impression upon the conception. Since then, ever-recurring characterizations of this figure are that he would appear as a mighty ruler at the head of gigantic armies, destroy three rulers (the three horns, Daniel 7:8, 24), persecute the saints (7:25), and devastate the Temple of God. In later times, the tyrant who was God's enemy became a figure of prophecy, applied to various situations of crisis. Also, Jewish and Christian writers of apocalypses saw in the emperor Nero (d. AD 68) the Antichrist.

A Christian view of the Antichrist is given in II Thessalonians 2. Here Antichrist appears as a tempter who works by signs and wonders and seeks to obtain divine honours; it is further signified that this "man of lawlessness" will obtain credence, especially among the Jews because they have not accepted the truth. This version of the figure of Antichrist, who may now really for the first time be described by this name, appears to have been at once widely accepted in Christendom. The idea that the Jews would believe in Antichrist as punishment for not having believed in the true Christ seems to be expressed by the author of the Fourth Gospel (John 5:43). The conception of Antichrist as a perverter of men led naturally to his connection with false doctrine (I John 2:18, 22, 4:3; II John 7). In the

Book of Revelation the Antichrist is seen as a worker of wonders and a seducer.

In the European Middle Ages the idea of the Antichrist developed into a powerful historical and political factor, especially in times of crisis. Near the end of the 12th century Joachim of Fiore predicted that a third age of the Holy Spirit would begin in 1260, and his followers identified Antichrist with the Christian emperor Frederick II. Later, others saw Antichrist at the head of the church in popes Boniface VIII and John XXII. It became common for opponents, including popes and emperors, to call each other the Antichrist.

Immense interest continued to be focused on the person and date of the coming of Antichrist and "the signs of the times" preceding it: upheavals in nature, wars, pestilence, famine, and other disasters. Preachers spread warnings of the coming of Antichrist in order to call the people to repentance throughout the 14th and 15th centuries.

During the Reformation, the Reformers, especially Martin Luther, did not attack individual popes but the papacy itself as Antichrist. This idea that evil was embodied in the head of the church itself, with the clergy as the "body of the Antichrist," became the most powerful weapon to discredit and denigrate the papacy.

After the Reformation, emphasis on the Antichrist figure gradually diminished. Among some modern Protestant theologians the Antichrist can be interpreted as whatever resists or denies the lordship of Christ and tends to deify a political power—within either the church or the state. In dispensational and premillennial theology the expectancy of a personal Antichrist at the end of time remains strong.

Consult the INDEX first

anticlericalism, in Roman Catholicism, opposition to the clergy for its real or alleged influence in political and social affairs, for its doctrinairism, for its privileges or property, or for any other reason. Although the term has been used in Europe since the 12th and 13th centuries, it is associated in more recent history with the French Revolution and its aftermath.

Three principal forms can be identified. The first, developed during the 18th century, was based on opposition to clerical privilege, often corrupt, as established by feudalism. The second is associated with the rise of liberalism, which in general accused the clergy of servility to the monarchy or of ignorance in terms of scientific thought. The third, endorsed by some totalitarian systems, considered clerics to be chronically opposed to the "race," the "nation," or some other presumed ideology.

France. In the 18th century such skeptics as Voltaire and the Encyclopaedists chafed under royal censorship and the clergy's influence on the monarchy. The culmination of such anticlericalism was the French Revolutionaries' assault on the Roman Catholic church, abolishing its privileges and confiscating property. In 1801 Napoleon Bonaparte ended the Revolution, signed a concordat with the papacy, and "established" the church as a religious agency supported by and subservient to the French state. With modifications, this system lasted for a century, during monarchist, republican, and Bonapartist regimes.

The creation of the Third Republic in 1871, however, intensified the old-time conflict between clericals and anticlericals. In the struggle between 1871 and 1879, royalist-clerical parties opposed republican-anticlerical parties. Léon Gambetta phrased the slogan, *le cléricalisme, voilà l'ennemi* ("clericalism is the enemy"). The victorious republicans enacted a good deal of anticlerical legislation. The Jesuits were suppressed (1880); and the Ferry laws (1881-82) established free, secular ed-

ucation, compulsory civil marriage, and the opportunity for divorce. The second conflict took place as a result of the bid of Georges Boulanger for dictatorial powers, and ended with a republican, anticlerical triumph. The third took place during the Alfred Dreyfus affair (1894-1906), when an anticlerical republican bloc was formed, consisting of all republican groups in the Chamber of Deputies, determined to oust royalists, militarists, and clericals from public life. Further anticlerical legislation resulted. The Law of Associations (1901) suppressed nearly all of the religious orders in France and confiscated their property, and the separation law (1905) sundered church and state.

Italy. Spreading from France, anticlerical ideas and methods were adopted, in varying ways, in other Latin countries. In Italy anticlericalism was fused with nationalism and liberalism. Pope Pius IX, defending his position as temporal ruler of the Papal States, opposed Italian unity. When Camillo Cavour embarked on his career as architect of a united Italy, he put through the Piedmontese Parliament a series of anticlerical laws, abolishing the civil jurisdiction of canonical courts and suppressing many monasteries. Cavour's slogan, "a free church in a free state," was adopted by the anticlerical liberals of Italy.

After the unification of Italy, the struggle between clericals and anticlericals continued. When Rome became the capital, the temporal power of the popes was ended. Anticlerical legislation decreased the number of monastic establishments, suppressed university theological faculties, and sanctioned civil marriage. But no divorce law was enacted, nor was religious instruction banned from the schools. The Law of Guarantees accorded the pope full power to exercise his spiritual function. Pius IX did not, however, recognize the Italian government and in 1874 forbade Catholics to participate in political activities. This caveat was not ended until 1919. The advent to power of Benito Mussolini in 1922 for a time intensified anticlericalism, since Fascism claimed absolute control by the state. Yet no serious conflict occurred, despite continuing papal opposition to some curtailments of religious liberty. In 1929 the Lateran Treaty was signed, ending the dispute over the temporal power by making the pope ruler of the small state of Vatican City.

Spain. The Napoleonic invasion (1808) started an anticlerical movement in Spain. The Constitution of 1812 abolished the Inquisition and restricted the number of religious orders but recognized Catholicism as the established church. This constitution was in turn abrogated when Ferdinand VII was restored to the throne in 1814. Anticlericals reacted bitterly, and from that time until 1939 the struggle between the right and left in Spain was far more a conflict between clericals and anticlericals than elsewhere in Latin Europe. The conflict became especially intense after 1870. Barcelona, traditionally a centre of anti-Catholic feeling, witnessed the formation of powerful syndicalist and anarchist groups. The first Spanish Republic (1873) enacted some anticlerical laws, but these were repealed or disregarded when the monarchy was restored in 1875. During an anticlerical outbreak in 1909, mobs burned churches and attacked priests. As a pacification measure, religious orders were restricted in number and taxes were levied on their industrial enterprises. Civil marriage was made compulsory. The revolution of 1931 that established the Second Republic brought to power an anticlerical government. The legislation adopted resembled that of France. The government was, however, unable to curb mob attacks on churches and monasteries, during which priests and nuns were slain. Catholics mustered their forces in opposition. Counterrevolutionaries led by General Francisco Franco declared war on

the republic, and the Falangist dictatorship that was subsequently established repealed or ignored the anticlerical laws, though conflict between church and state did not cease, even after the death of Franco in 1975.

Latin America. Anticlerical tendencies varied considerably from country to country in Latin America after it had achieved independence from Spain and Portugal. Although Colombia, for example, witnessed the enactment of anticlerical legislation and its enforcement during more than three decades (1849–84), it soon restored “full liberty and independence from the civil power” to the Roman Catholic church (1888). In Venezuela, on the other hand, the government of Antonio Guzmán Blanco (1870–88) virtually crushed the institutional life of the church, even attempting to legalize the marriage of priests. Some of the restrictions were later relaxed, but on the whole anticlericalism remained dominant. A strong outburst of anticlerical resentment occurred in Mexico in the period from 1924 to 1938, when suppressive anticlerical legislation accompanied social reforms. Anticlerical legislation remained on the statute books in subsequent decades, but the Roman Catholic clergy could work more freely than before.

Germany. Anticlericalism was not novel in Germany, but it was strengthened intellectually by ideas generally accepted during the French Revolution. Free thought, with its principle of the “lay state,” made headway particularly in southern Germany and played a part in the revolutionary incidents of 1848. The rise of Marxian socialism likewise brought large segments of the working population into the anticlerical camp. But Roman Catholics in the populous Rhenish areas were mostly constitutionalists, in sympathy with some tenets of liberalism. Their political program, which led to the formation of the Centre Party, included the defense of the right of all religious minorities.

Shortly after the unification of Germany in 1871, Chancellor Otto von Bismarck, adopting part of the liberal program, began the *Kulturkampf*, a series of attacks on the Roman Catholic church. Anticlerical legislation was enacted: the number of religious orders was restricted, the Jesuits were banned, civil marriage was sanctioned, and uncooperative priests were removed from their parishes. Resistance was punished, and some bishops were deposed. Most of the anticlerical legislation was removed from the statute books in the 1880s. The prohibition of the Jesuits remained in force, however, until 1917.

anticoagulant, any substance that, when added to blood, prevents it from clotting. Anticoagulants achieve their effect by suppressing the synthesis or function of various clotting factors that are normally present in the blood. Such drugs are often used to prevent blood clots (thrombi) from forming in the veins or arteries. Anticoagulants are generally of two types. One type is heparin (*q.v.*), a mucopolysaccharide that promotes the activity of antithrombin III, a blood plasma protein that inactivates thrombin (an enzyme that promotes clotting). The other type consists of the vitamin K antagonists, a group of agents that differ from heparin primarily in their longer duration of action; of these, the most widely used is warfarin. Vitamin K antagonists interfere in the metabolism of that vitamin in the liver. Since vitamin K is an important element in the synthesis of various clotting factors, interference in the metabolism of that vitamin gives rise to clotting factors that are defective and hence inactive in the blood. A major side effect of anticoagulant therapy is hemorrhage. Anticoagulants are also used in drawing and storing blood.

Anticona (Peru): *see* Ticlio.

anticorona: *see* Brocken bow.

Anticosti Island, French ÎLE-D'ANTICOSTI, island in the Gulf of St. Lawrence at the mouth of the St. Lawrence River, part of the Côte-Nord region, southeastern Quebec province, Canada. Covering 3,066 square miles (7,941 square km), the island is 140 miles (225 km) long, and its greatest width is 35 miles (56 km). Anticosti rises to 625 feet (191 m) in hills along its north coast; it is well forested with spruce, fir, and pine. The island is a hazard to shipping.

The island was discovered by the French navigator Jacques Cartier in 1534 and named Assomption. Since the 17th century, it has been called Anticosti, a name probably derived from the Indian word *naticosti*, meaning “where bears are hunted.”

Granted to the French explorer Louis Jolliet in 1680, it was ceded by France to Great Britain in 1763 and was annexed to Newfoundland. It became part of Quebec province in 1774. After attempts to settle Anticosti failed, it was leased in 1895 by Henri Menier, a French chocolate manufacturer, who developed its resources. Menier's brother Gaston transferred ownership in 1926 to a Canadian paper corporation. Baie-Sainte-Claire was the

Anticosti Island

first permanent settlement, but nearby Port-Menier, also called Baie-Ellis, is the island's only contemporary settlement and is a lumber port. Pop. (1991) 264.

anticyclone, any large wind system occurring in regions outside the equatorial belt and rotating about a centre of high atmospheric pressure clockwise in the Northern Hemisphere and counterclockwise in the Southern. Its flow is the reverse of that of a cyclone (*q.v.*).

antidepressant, any member of a class of drugs used in psychiatry to relieve depression. Such a drug commonly belongs to one of three chemical types: a tricyclic antidepressant (so called because its molecules are composed of three rings), a monoamine oxidase (MAO) inhibitor, or a serotonin reuptake inhibitor.

Introduced in the late 1950s, antidepressant drugs have been used most widely in the management of major mental depression. Chemically speaking, depression is apparently caused by reduced quantities or reduced activity of the monoamine neurotransmitters serotonin and norepinephrine within the brain. All antidepressants achieve their effects by inhibiting the body's reabsorption or inactivation of these neurotransmitters, thus allowing them to accumulate and remain in contact longer with their receptors in nerve cells; these changes seem to be important in elevating mood and relieving depression.

The tricyclic antidepressants act by inhibiting the inactivation of norepinephrine and serotonin within the brain. The tricyclics include imipramine, amitriptyline, desipramine, nortriptyline, and a number of other compounds. These drugs relieve symptoms in a high proportion (more than 70 percent) of depressed patients. As with the MAOs, the antidepressant action of tricyclic drugs may not become apparent until two to four weeks after treatment begins. The possible side effects include dry mouth, blurred vision, constipation, dizziness, and difficulty in urination. Cerebral and

cardiac toxicity have been observed in some individuals.

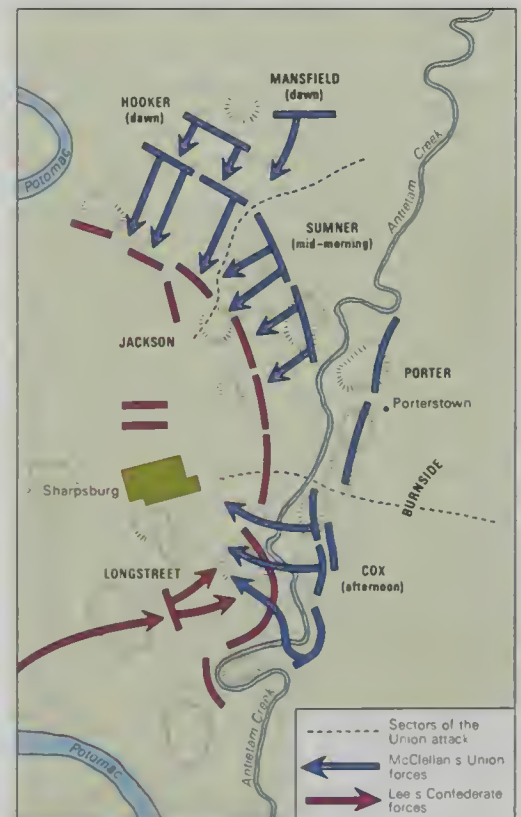

The monoamine oxidase inhibitors—chiefly isocarboxazid, phenelzine, and tranylcypromine—in general are used only after treatment with tricyclic drugs has proved unsatisfactory, because these drugs' side effects are unpredictable and their complex interactions are incompletely understood. The MAOs apparently achieve their effect by interfering with the action of monoamine oxidase, an enzyme that is involved with the breakdown of norepinephrine, serotonin, and dopamine within nerve cells.

In the 1980s a new type of antidepressant called a serotonin reuptake inhibitor proved markedly successful. Called fluoxetine, it apparently achieves its therapeutic effect by interfering solely with the reabsorption of serotonin within the brain, thus allowing that neurotransmitter to accumulate there. Fluoxetine often relieves cases of depression that have failed to yield to tricyclics or MAOs, and it also produces fewer and less serious side effects than those drugs. It had thus become the single most widely used antidepressant by the end of the 20th century.

antideuteron, composite antiparticle consisting of an antiproton and an antineutron, first produced with a 30-GeV (giga-electron volt) synchrotron at Brookhaven National Laboratory, Long Island, N.Y., in 1965. Having a charge of negative one unit and an atomic mass of two units, it may be considered as the antinucleus of the hydrogen isotope deuterium.

Antietam, Battle of, also called BATTLE OF SHARPSBURG (Sept. 17, 1862), a decisive engagement in the American Civil War (1861–65) that halted the Confederate advance on Maryland for the purpose of gaining military supplies. The advance was also regarded as one of the greatest Confederate threats to Washington, D.C. The battle took its name from Antietam Creek, which flows south from Gettysburg, Pa., to the Potomac River near Harpers Ferry, W.Va.

Following the Union defeat at the Sec-

The Battle of Antietam, Sept. 17, 1862

ond Battle of Bull Run, Confederate General Robert E. Lee advanced into Maryland with some hope of capturing the Federal capital of Washington to the southeast. On Sept. 17, 1862, his forces were met at Antietam by the reorganized Federal Army under General George B. McClellan, who blocked Lee's advances but allowed him to retire to Virginia. Most military historians have strongly criticized McClellan's conduct of the battle, which proved to be one of the bloodiest single days of the war. The South lost more than 10,700 troops and the North suffered casualties of about 12,400.

In addition to protecting the Federal capital, the battle is sometimes cited as having influenced Great Britain not to recognize the Confederacy. President Abraham Lincoln used the occasion of the Antietam victory to issue his preliminary Emancipation Proclamation (Sept. 22, 1862), announcing that unless the Confederates laid down their arms by Jan. 1, 1863, he would free their slaves.

antiferromagnetism, type of magnetism in solids such as manganese oxide (MnO) in which adjacent ions that behave as tiny magnets (in this case manganese ions, Mn^{2+}) spontaneously align themselves at relatively low temperatures into opposite, or antiparallel, arrangement throughout the material so that it exhibits almost no gross external magnetism. In antiferromagnetic materials, which include certain metals and alloys in addition to some ionic solids, the magnetism from magnetic atoms or ions oriented in one direction is canceled out by the set of magnetic atoms or ions that are aligned in the reverse direction.

This spontaneous antiparallel coupling of atomic magnets is disrupted by heating and disappears entirely above a certain temperature, called the Néel temperature, characteristic of each antiferromagnetic material. (The Néel temperature is named for Louis Néel, French physicist, who in 1936 gave one of the first explanations of antiferromagnetism.) Some antiferromagnetic materials have Néel temperatures at, or even several hundred degrees above, room temperature, but usually these temperatures are lower. The Néel temperature for manganese oxide, for example, is 122 K ($-151^{\circ}C$, or $-240^{\circ}F$).

Antiferromagnetic solids exhibit special behaviour in an applied magnetic field depending upon the temperature. At very low temperatures, the solid exhibits no response to the external field, because the antiparallel ordering of atomic magnets is rigidly maintained. At higher temperatures, some atoms break free of the orderly arrangement and align with the external field. This alignment and the weak magnetism it produces in the solid reach their peak at the Néel temperature. Above this temperature, thermal agitation progressively prevents alignment of the atoms with the magnetic field, so that the weak magnetism produced in the solid by the alignment of its atoms continuously decreases as temperature is increased.

antigen, foreign substance that, when introduced into the body, is capable of adhering to lymphocytes, which are the body's infection-fighting white blood cells. An antigen that induces an immune response—*i.e.*, stimulates the lymphocytes to produce antibody or to attack the antigen directly—is called an immunogen. Virtually any large foreign molecule can act as an antigen, including those contained in bacteria, viruses, protozoa, helminths, foods, snake venoms, egg white, serum components, red blood cells, and other cells and tissues of various species, including humans. On the surface of the antigens are molecules, called antigenic determinants, that fit and bind to receptor molecules of com-

plementary structure on the surface of the lymphocytes. The binding of the lymphocytes' receptors to the antigens' surface molecules stimulates the lymphocytes to multiply and to initiate an immune response—including the production of antibody, the activation of cytotoxic cells, or both—against the antigen (*see* immunity). The amount of antibody formed in response to stimulation depends on the kind and amount of antigen involved, the route of entry to the body, and individual characteristics of the host. *See also* antibody; lymphocyte.

Antigone, in Greek legend, the daughter born of the unwittingly incestuous union of Oedipus (*q.v.*) and his mother, Jocasta. After her father blinded himself upon discovering that Jocasta was his mother and that, also unwittingly, he had slain his father, Antigone and her sister Ismene served as Oedipus' guides, following him from Thebes into exile until his death near Athens. Returning to Thebes, they attempted to reconcile their quarreling brothers—Eteocles, who was defending the city and his crown, and Polyneices, who was attacking Thebes. Both brothers, however, were killed, and their uncle Creon became king. After performing an elaborate funeral service for Eteocles, he forbade the removal of the corpse of Polyneices, condemning it to lie unburied, declaring him to have been a traitor. Antigone, moved by love for her brother and convinced of the injustice of the command, buried Polyneices secretly. For that she was ordered by Creon to be executed and was immured in a cave, where she hanged herself. Her beloved, Haemon, son of Creon, committed suicide. (This is according to Sophocles' *Antigone*, but according to Euripides, Antigone escaped and lived happily with Haemon.)

Antigonid DYNASTY, ruling house of ancient Macedonia from 306 to 168 BC. The Antigonid dynasty was established when Demetrius I Poliorcetes, the son of Antigonus I Monophthalmus, ousted Cassander's governor of Athens, Demetrius of Phaleron, and conquered the island of Cyprus, thereby giving his father control of the Aegean, the eastern Mediterranean, and all of the Middle East except Babylonia. Antigonus I was proclaimed king in 306 by the assembled army of these areas.

Demetrius succeeded Antigonus I to the throne, and his son, Antigonus II Gonatas, strengthened the Macedonian kingdom by routing a band of Galatian invaders from Macedonia. In 239 Gonatas died, his resilience and solid work having given Macedonia a sound and durable government. Gonatas' son Demetrius II (reigned 239–229 BC) at once became involved in a war with the Greek Achaean and Aetolian leagues that lasted until his death. Macedonia was weakened, and Demetrius' heir, Philip V, was a child. Conditions became so unsettled that the child's guardian, Antigonus Doson, took the throne as Antigonus III. He marched into Greece and, after defeating the Spartan king Cleomenes III at Sellasia (222), reestablished the Hellenic Alliance as a confederacy of leagues, with himself as president. Doson died in 221, having restored internal stability and reestablished Macedonia in a stronger position in Greece than it had enjoyed since the reign of Gonatas.

Under Philip V, Macedonia first clashed with Rome (215), but Philip seriously miscalculated Rome's strength, and his defeat at Cynoscephalae (197) led to a peace that confined him to Macedonia. The Hellenic Alliance, which had fallen apart, was replaced by a series of leagues in former Macedonian areas. Above all, the old balance of power was upset and Rome became the decisive power in the eastern Mediterranean.

Philip's successor, Perseus (reigned 179–168 BC), was recognized as a champion of Greek freedom against Rome. But Perseus' failure

to deploy his full resources brought about his defeat (168) at Pydna in Macedonia and signaled the end of the dynasty.

Antigonish, town, seat of Antigonish county, northeastern Nova Scotia, Canada. It lies at the head of Antigonish Bay, an inlet of St. Georges Bay, 31 miles (50 km) east of New Glasgow. The site was originally settled by the French in 1762; the first British immigrants (soldiers and Scottish Highlanders) did not arrive until after 1785. The earlier name, Dorchester, was replaced by Antigonish, a word that is of Micmac Indian origin and has a disputed meaning—either "broken branches" or "river of fish."

Antigonish is now chiefly residential, but lumber, farm products, and fish are exported, and gypsum and limestone are quarried nearby. It is the seat of a Roman Catholic diocese, and St. Ninian's Cathedral dates from about 1875. The town is the seat of Mount St. Bernard's College (1883) and of St. Francis Xavier University (1853), where the Antigonish Movement, a cooperative, self-help program, was instituted in 1930. The Highland Games, patterned after the Braemar Games of Scotland, are held there annually in mid-July. Inc. 1889. Pop. (1991) 4,924.

Antigonus I MONOPHTHALMUS ("One-Eyed"), also called ANTIGONUS I CYCLOPS (b. 382 BC—d. 301, Ipsus, Phrygia, Asia Minor [now in Turkey]), Macedonian general under Alexander the Great who founded the Macedonian dynasty of the Antigonids (306–168 BC), becoming king in 306. An exceptional strategist and combat leader, he was also an astute ruler who cultivated the friendship of Athens and other Greek city-states.

Military campaigns. In 333 Alexander had appointed Antigonus satrap of Phrygia, and upon Alexander's death he also received the governorship of Pamphylia and Lycia from the regent of the Macedonian empire, Perdiccas. He then formed an alliance against Perdiccas with Antipater, the governor of Macedonia, and with Ptolemy of Egypt, Lysimachus of Thrace, and Craterus (all of whom had served under Alexander). Perdiccas was murdered, and Antipater became regent of the empire. In 321 Antipater appointed Antigonus commander in chief of his army in Asia and sent him against Eumenes, the satrap of Cappadocia and an adherent of Perdiccas. Antigonus defeated Eumenes and then besieged him unsuccessfully in the mountain fortress Nora. Polyperchon succeeded Antipater as regent, and Antigonus joined forces against him with Cassander (Antipater's son), Ptolemy, Lysimachus, and Eumenes in 319. When Eumenes, his rival in Asia Minor (Anatolia), went over to Polyperchon, Antigonus defeated him with the aid of Seleucus and Peithon (the satraps of Babylonia and Media, respectively) at Gabiene. Then, wishing to eliminate all possible rivals, Antigonus had both Eumenes and Peithon executed; Seleucus escaped to Egypt.

Antigonus was now in complete control of Asia Minor, but Ptolemy, Lysimachus, Cassander, and Seleucus allied themselves against him in the first coalition war (315–311) in an attempt to thwart his plan of reuniting Alexander's empire. Antigonus occupied Syria and proclaimed himself regent. In order to win the support of the Greek city-states, whose resistance to subjugation presented the chief stumbling block to the formation of a Hellenistic monarchy, he announced to his assembled army that all the Greeks should be free, autonomous, and ungarrisoned. This political slogan was to be sounded again and again—almost immediately by Ptolemy and for a final time by the Romans in 196. With the aid of his officers in Greece, Antigonus drove out Cassander's Macedonian forces of occupation there and formed the island cities in the Aegean into the League of the Islanders, preparatory to his invasion of Greece. His

ally, the city of Rhodes, furnished him with the necessary fleet.

While he was engaged in conquering Caria, his son, Demetrius Poliorcetes, was defeated at Gaza by Ptolemy and Seleucus (312). Seleucus returned to his former province, Babylonia. In view of this new threat from the East, Antigonus decided to make peace with all of his adversaries except Seleucus. All of the *diadochoi* (Alexander's successors) confirmed the existing boundaries and the freedom of the Greek cities. Antigonus, no longer regent but merely *stratēgos* (officer in charge) of the whole of Asia, was to rule in Syria and from the Hellespont to the Euphrates.

Activities in Greece. Then Ptolemy attacked Cilicia, and the second coalition war (310–301) against Antigonus broke out. In Greece in 307, Antigonus' son Demetrius ousted Demetrius of Phaleron, Cassander's governor of Athens, and reestablished the old Athenian constitution. The grateful Athenians honoured Antigonus and Demetrius as divine saviours (*theoi sōtēres*). Cassander's influence in Greece was now broken, and in 306 Demetrius defeated Ptolemy's fleet near Salamis on the island of Cyprus and conquered the island. This victory gave Antigonus control of the Aegean, of the eastern Mediterranean, and of all of the Near East except Babylonia. The assembled army proclaimed him king, and his friends adorned him with the diadem. For his part, he appointed Demetrius king and coregent and sent him the diadem. This was to become a traditional ceremony in the Hellenistic monarchy.

In 305, after Antigonus had vainly attacked Egypt, Ptolemy also assumed the title of king, and Cassander, Lysimachus, and Seleucus followed suit. The partition of Alexander's empire into five states had now been formally established. In 305 Antigonus sent Demetrius to conquer Rhodes, which had refused him armed support against Ptolemy. After a year's unsuccessful siege he concluded a peace treaty and an alliance with the island state, guaranteeing it autonomy and neutrality in his conflicts with Ptolemy. This concession was necessary because in the meantime Cassander had invaded Attica and was besieging Athens. Demetrius drove him out of central Greece, and the Athenians bestowed on him a new religious honour, *synnaos* ("having the same temple") of the temple of the goddess Athena.

In 303 he occupied Corinth, Sicyon, and Argos in the Peloponnese, and Achaea, Elis, and almost all of Arcadia joined his side. In 302 Antigonus and Demetrius crowned their success by renewing the pan-Hellenic league, which Philip II of Macedonia had formed in 337. Ambassadors from all the Hellenic states—with the exception of Sparta, Messenia, and Thessaly—elected Antigonus and Demetrius protectors of the new league at Corinth. It was to be an "eternal" treaty, extending to the descendants of the kings. Each member state furnished a contingent of troops for a league army that was commanded by the kings or their deputies. The league was to ensure a general peace in Hellas, but first and foremost it was to aid Antigonus against Cassander.

Final campaigns. Now at the zenith of his power, Antigonus demanded Cassander's unconditional submission. He wanted possession of Macedonia, the native land of his dynasty, and to establish his dominion over Alexander's former empire. The other *diadochoi*, however, warned by Cassander's fate, now joined forces to attack the omnivorous old man. From Babylonia, Seleucus invaded Asia Minor, Ptolemy attacked Syria, and Lysimachus moved into the western part of Asia Minor. Docimus, the regent of Phrygia, and Phoenix, the *stratēgos* of Lycia, deserted Antigonus. He, in turn, recalled Demetrius, left his capital city, Antigoneia (which he had founded on the Orontes in 306), and crossed the Tau-

rus Mountains. Lysimachus, who was waiting for Seleucus, avoided an engagement. In vain Antigonus sent a corps of raiders into Babylonia in order to divide his enemies' forces. In 301 the united armies of Lysimachus and Seleucus engaged the forces of Antigonus and Demetrius at Ipsus in Phrygia. Demetrius made the error of pursuing the enemy's cavalry too far, and as a result Antigonus, age 80, lost the battle and his life.

Antigonus had been an excellent strategist who, until then, had never lost a battle. He had a genuine admiration for Greek civilization. He founded several cities, especially in Asia Minor, and united several small communities into unitary, large centres: Lebedus (Lebedos) and Teos, for example. Several Greek artists graced his court; Apelles painted his portrait in profile because of his missing eye (the cause of which is unknown). (H.V.)

BIBLIOGRAPHY. C. Wehrli, *Antigone et Demetrios* (1968), a comprehensive biography with a discussion of sources and literature; H.H. Schmitt, *Die Verträge der griechisch-römischen Welt von 338 bis 200 v. Chr.* (1969), treats the foundation of the Hellenic union.

Antigonus II GONATAS (b. c. 319 BC—d. 239), king of Macedonia from 276 BC who rebuilt his kingdom's power and established its hegemony over Greece.

Antigonus II was the son of Demetrius I Poliorcetes and grandson of Antigonus I. While his father, Demetrius, was busy fighting in Macedonia and Asia Minor against Lysimachus of Thrace, Ptolemy I of Egypt, Pyrrhus of Epirus, and Seleucus I, Antigonus, as his regent, was engaged in maintaining Macedonian hegemony in Greece, which had been achieved in 287 BC. Demetrius was taken prisoner in 285 by Seleucus, who then claimed the Macedonian kingship. This contested title was assumed by Antigonus himself on the death of his father two years later; however, he did not count the beginning of his reign until 276. Although he had only a few bases in Greece, Antigonus laid claim to Macedonia when Seleucus was murdered in 281. His claim was disputed by Seleucus' successor, Antiochus I. Antigonus took part in the defense of Greece against the invading Celts (279). In the following year he concluded a peace with Antiochus. This surrendered his claim to Macedonia. Thereafter Antigonus' foreign policy was marked by friendship with the Seleucids.

In 277 he crossed the Hellespont and defeated the Celts near Lysimacheia. After this success he was acknowledged king by the Macedonians in 276. Pyrrhus, returning in 274 after the failure of his campaign in Italy, drove Antigonus out of Upper Macedonia and Thessaly. Although he retained only a few Macedonian cities, Antigonus followed Pyrrhus when the latter marched into the Peloponnese; and when Pyrrhus died in Argos in 272, Antigonus' control over Macedonia was assured. He was now also the chief of the Thessalian League and on good terms with neighbouring Illyria and Thrace. He secured his position in Greece by keeping Macedonian occupation forces in the cities of Corinth, Chalcis on Euboea, and Demetrias in Thessaly, the three "shackles" of Hellas.

Beyond that he supported the pro-Macedonian faction in various cities in the Peloponnese and the rise to power of tyrants in Sicyon, Argos, Elis, and Megalopolis. In order to keep Greece in a state of complete dependency by controlling the straits and the supply of grain from the southern Russian region, Macedonia—its vigour restored—needed only to gain mastery over the Aegean Sea. To avert this danger, King Areus of Sparta and the city of Athens—urged on by Ptolemy II of Egypt—declared a war for the liberation of Greece (the Chremonidean War, 267–261). Although the Egyptian fleet had blockaded the Saronic Gulf, Antigonus defeated the King of Sparta

near Corinth in 265 and then besieged Athens. In 263–262 the city capitulated. Athenian officials were replaced by Antigonus' appointees, and Athens became no more than a Macedonian provincial city.

Immediately after the Chremonidean War, Antigonus joined forces with the Seleucid Antiochus II against their common enemy, Ptolemy II. Whether his naval victory of Cos, which secured Antigonus the Aegean Sea and the League of the Islanders, belongs to this (255) or to the Chremonidean War (261) is uncertain. In 255 a peace was concluded with Ptolemy, and by marrying his stepbrother Demetrius the Fair to Berenice of Cyrene, Antigonus established Macedonian influence in this neighbour country of Egypt.

But his position in Greece was now shaken by a number of reversals. In 253 Alexander, Antigonus' nephew and regent, revolted in Corinth with Ptolemy's help and declared himself an independent monarch. Antigonus lost Corinth and Chalcis, the two bases from which he dominated southern Greece. As the Aetolians had occupied Thermopylae, he was cut off from Athens and the Peloponnese. After Alexander's death, however, Antigonus gave Nicaea, Alexander's widow, to his son Demetrius in marriage and by means of a stratagem regained Corinth in 244. In the meantime the Achaean League was becoming a dangerous opponent. Since 251 it had been under the leadership of Aratus of Sicyon and was receiving financial aid from Ptolemy II. In vain, Antigonus sent gifts to win over Aratus. In 243, without a declaration of hostilities, Aratus made a surprise attack on Corinth and forced the withdrawal of the Macedonian occupation troops. Megara, Troezen, and Epidaurus also deserted Antigonus. He made no attempt to regain these territories but instead formed an alliance with the Aetolian League, which made unsuccessful raids of pillage into the Peloponnese. Nevertheless, by defeating the Egyptian fleet at Andros c. 244 Antigonus was able to maintain his hegemony in the Aegean. After a life of endless warfare he died in 239 at 80 years of age.

Personally, Antigonus was unassuming, short of stature, and snub-nosed. In Macedonia the cult of the ruler, so usual in the other Hellenistic states, was unknown. He chose his friends not because of their noble ancestry but for their personal abilities. He conceived his monarchic rule in philosophical terms—*i.e.*, by the strict observance of his duties as a ruler. Once, when his son treated some subjects arbitrarily, he said to him: "Do you not understand that our kingship is a noble servitude [*endoxos douleia*]?" This paradoxical concept of monarchy envisaged the ruler as bearing the burden of his office, serving the people and the law. In his youth Antigonus had been a student of Zeno, the founder of Stoicism. He had been taught by him in Athens and in 276 invited him to his court in Pella in Macedonia. The philosopher, however, did not come and instead sent two of his students, Persaeus and the Theban Philonides. Persaeus wrote a treatise on kingship, was the mentor of Halcyoneus, the son of Antigonus, and became commandant of Corinth in 244. When Zeno died in 263 the King lamented that he had lost the only man whose judgment of his public actions he valued, and he prevailed upon the Athenians to bury him in state. Among the literati at his court was the historian Hieronymus of Cardia, who recorded the war with Pyrrhus, and the poet Aratus, a native of Cilicia, author of the much read didactic poem on astronomy, *Phaenomena*.

(H.V.)

Antigonus." *Am. J. Philology*, 75:385-394 (1954), provides the dating for his reign; H. Volkmann, *Historia*, 16:155-161 (1967), comments upon the notion of noble servitude (in German).

Antigonus III DOSON (b. c. 263 BC—d. c. 221 BC), king of Macedonia (from 227 BC) who, in defeating Cleomenes of Sparta, ended that city's long independence. His surname may have signified "one who is about to give but never does."

Antigonus, a descendant of Antigonus I, was the son of Demetrius II (a half brother of Antigonus II) and Olympias of Larissa. On the death of Demetrius II (229 BC), Antigonus was made guardian of his son Philip. After two years, Antigonus married Demetrius' widow, Pthia, and assumed the crown.

His first military task was to secure Macedonia against barbarians on its borders. He then became involved in Greek affairs, in which he displayed exceptional statesmanship. He supported Aratus and the Achaean League in their opposition to Cleomenes, king of Sparta, and the Aetolians. After several years of war, Cleomenes was defeated (222 BC), and Antigonus occupied Sparta. He soon had to return to Macedonia to face an invasion by Illyrians, whom he defeated. Polybius mentions Antigonus as being a wise and moderate ruler. He was succeeded as king of Macedonia by his stepson, Philip V.

antigorite, mineral, a polymorph of serpentine (*q.v.*).

Antigua and Barbuda, island nation of the Lesser Antilles in the eastern Caribbean Sea. It is composed of three islands, namely Antigua, Barbuda, and uninhabited Redonda, and covers an area of 171 square miles (442 square km). Formerly British colonies, the islands had free-association status with the United Kingdom from 1967 and achieved full independence in 1981. The capital is St. John's on Antigua. The nation's nearby neighbours include Anguilla to the northwest, St. Kitts and Nevis to the west, and Montserrat to the southwest. The Atlantic Ocean washes Antigua's northeastern shore. The population in 1990 was estimated to be 79,000.

For information about regional aspects of Antigua and Barbuda, see MACROPAEDIA: West Indies.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

The land. The largest of the islands, Antigua, covers a total area of 108 square miles

chorges include the deepwater harbour of St. John's and the shallower harbours of Parham and English. The mean annual temperature of Antigua is about 81° F (27° C). Temperatures vary little from month to month, and the annual rainfall averages about 40 inches (1,000 mm), which is relatively sparse compared with other islands of the Lesser Antilles. Antigua and the nation's other islands lie in the path

Nelsons Dockyard in English Harbour, Antigua and Barbuda

of the seasonal hurricanes that occur in the West Indies.

Barbuda, formerly Dulcina, lies 25 miles (40 km) north of Antigua and covers 62 square miles (161 square km). It is a coral island, flat and well-wooded, with highlands rising to 143 feet (44 m) at Lindsay Hill in the northeast. A game reserve, Barbuda is inhabited by a variety of wildlife, including duck, guinea fowl, plover, pigeon, wild deer, and wild pig. The only settlement on Barbuda is Codrington, which is situated on a lagoon on the west side of the island.

Redonda, an uninhabited rock covering 0.5 square mile (1.3 square km) and rising sheer to 1,000 feet (305 m), lies 25 miles (40 km) southwest of Antigua proper. Phosphate deposits are located there.

The people. The vast majority of the population of Antigua and Barbuda is made up of the descendants of African slaves who were brought there during colonial times to work on the islands' sugar plantations. Today the people are largely engaged in tourism and in agricultural pursuits. The main settlements are St. John's on Antigua and Codrington on Barbuda. The language is English, and the vast majority of the population are Christians, with the Anglican church being predominant. The average life expectancy is about 72 years.

The economy. Antigua and Barbuda has experienced a slow but steady growth in its economy since the late 1970s. The gross national product (GNP) is growing more rapidly than the population; the GNP per capita is fairly high for a Caribbean nation. Tourism is the mainstay of the economy, accounting for about 60 percent of the GNP when related services are taken into account.

From the 1950s agriculture's contribution to the GNP dropped dramatically, until in the late 1980s it was less than 5 percent. Over the same period the number of agricultural workers in the nation fell to about 2,100, or about one-fourth the number formerly employed in agriculture. A severe blow to the agricultural sector came in 1972 when the sugar industry closed down. Attempts were made in the early 1980s to replant some of the sugarcane fields and to restore the refinery, but, because of financial problems, the sugar industry was again closed in 1985. Sea Island cotton has traditionally been grown, and fruits, vegetables, and livestock are also raised. The fishing industry has grown in importance, especially after the government established a corporation for catching and processing fish, including lobster.

Manufacturing is in the development stage in Antigua and Barbuda. Most of the nation's

industries are involved with the processing of agricultural products, and the chief items produced include foods, clothing and textiles, concrete blocks, paints, optical lenses, and wood and paper products. Electronic components are assembled for export. The country's imports include mineral fuels, machinery and transport equipment, food and live animals, and chemical products. Antigua and Barbuda's main trading partners are the United States, the members of the Caribbean Community and Common Market (Caricom), and the United Kingdom.

Transportation on the islands is mainly provided by motor vehicles, and almost 50 percent of the roads are paved. The nation's main airfield, which handles international flights, is V.C. Bird (formerly Coolidge) on Antigua; there is another, smaller airfield on Barbuda. The main port is St. John's, with its deepwater harbour.

Government and social conditions. Antigua and Barbuda is an independent member of the Commonwealth. The 1981 constitution provides for a two-house parliamentary type of government. Members of the House of Representatives are elected every five years, and members of the Senate are appointed by the governor-general, who represents the British monarch as the country's head of state. The governor-general is advised in his Senate selections by the prime minister and the leader of the minority party.

Two welfare plans administered by the government are available to the islanders. One is a medical plan, which covers most expenses for medical treatment and hospitalization. The other is a social-security plan, which provides old-age pensions and a number of other benefits. The groundwater supply is augmented by distillation of seawater.

Basic education is compulsory, beginning at age 5 and lasting 11 years. The country also has a teachers' college and a technical and vocational school. The literacy rate is high and has been estimated at about 90 percent of the total population.

Radio and television broadcasting is controlled by a government agency. The country has several newspapers, all under private ownership.

Points of interest to visitors on Antigua include the colourful public market, the old Court House (1748-50) in which the parliament meets, and St. John's Cathedral (1847), all in St. John's. The annual Midsummer Carnival, second only to Trinidad's in size, includes calypso contests, processions, and other celebrations.

History. Christopher Columbus visited Antigua in 1493 and named it after the Church of Santa Maria de la Antigua in Seville, Spain. The island was colonized by English settlers beginning in 1632, and they imported African slaves to grow first tobacco and then sugarcane on large estates. Barbuda was colonized by the English in 1678. It was held by the Codrington family from 1685 until it reverted back to the British crown in the late 19th century, by which time it had become a dependency of Antigua. Though planned as a slave-breeding colony, Barbuda never became one. Instead, its slaves became self-reliant sailors, hunters, and fishermen who owned the land on Barbuda communally. In 1834 the slaves of Antigua were emancipated. Antigua (with Barbuda) was administratively a part of the British colony of the Leeward Islands from 1871 until that colony was defederated in 1956.

In 1958 Antigua joined the West Indies Federation, and, after that federation was dissolved in 1962, Antigua entered into free association with Great Britain in 1967, a relation under which Antigua received the right of self-government in all its internal affairs. Antigua and Barbuda achieved full independence from Britain in 1981.

Antigua and Barbuda

(280 square km). It lacks forests, mountains, and rivers and is subject to droughts. Though mostly low and undulating and underlain by limestone, the terrain rises westward in volcanic rocks that reach 1,330 feet (405 m) at Boggy Peak. The intricate coastline has bays and headlands fringed by reefs and shoals. An-

Antigua Guatemala, capital, Sacatepéquez department, southwestern Guatemala, at an altitude of 5,029 ft (1,533 m). Capital of the former captaincy general, Antigua Guatemala was once the most important seat of Spanish colonial government between Mexico City and Lima, Peru. Founded as Santiago de los Caballeros de Guatemala in 1527, it was destroyed by an eruption that swept down from the slopes of Volcán de Agua. The village

The colonial church of La Merced, Antigua Guatemala

Harrison Forman

that became reestablished on the site came to be called Ciudad Vieja ("old city"). Another capital city with the name Santiago was constructed in 1542 near the site of Ciudad Vieja, and it became a thriving political, economic, and cultural centre of some 60,000 persons. When Santiago was demolished by an earthquake in 1773, the capital was moved 15 mi (24 km) to the site of Nueva Guatemala ("new Guatemala"), the modern Guatemala City, and Santiago became known as Antigua Guatemala ("Guatemala of old"), or Antigua.

Antigua Guatemala is noted chiefly for the ruins of colonial edifices that make it a museum of Spanish colonial history. On or near the central plaza, several of the principal buildings of the colonial capital still serve public functions; and scattered throughout the city are numerous ruins of religious structures and rebuilt private dwellings. Antigua Guatemala has several modern hotels situated in quiet, picturesque surroundings. The grandeur of its setting at the base of towering volcanoes and its benign climate make the city a favourite resort and residential site. The annual Holy Week festival is one of the best known in the country. A paved highway connects the town with Guatemala City. Pop. (1994 prelim.) city, 16,357; mun., 34,168.

antihistamine, any of a group of synthetic drugs that selectively counteract the pharmacological effects of histamine (*q.v.*), following its release from certain large cells (mast cells). Antihistamines replace histamine at one or the other of the two sites at which it becomes bound to various susceptible tissues, thereby preventing histamine-triggered reactions under such conditions as stress, inflammation, and allergy.

The antihistamines first introduced are bound at the so-called H_1 sites; they are therefore designated H_1 -blocking agents and oppose selectively all the pharmacological effects of histamine except those on gastric secretion. Development of antihistamines dates from about 1937, when French workers discovered compounds that protected animals against both the lethal effects of histamine and those of anaphylactic shock. The first antihistamines were derivatives of ethylamine; aniline-type compounds, tested later and found to be more potent, were too toxic for clinical use. In 1942, the forerunner of most modern antihistamines (an aniline derivative called Antergan) was discovered; subsequently, compounds that were more potent, more specific, and less toxic were prepared. More than 100 antihistaminic compounds soon became available for treating patients.

Since histamine is involved in the production of some symptoms of allergy and anaphylaxis,

antihistamines can control certain allergic conditions, among them hay fever and vasomotor rhinitis; the nasal irritation and watery discharge are most readily relieved. Persons with urticaria, edema, itching, and certain sensitivity reactions respond well. Antihistamines are not usually beneficial in treating the common cold and asthma. Antihistamines with powerful antiemetic properties are used in the treatment of motion sickness and vomiting. Used in sufficiently large doses, nearly all antihistamines produce undesirable side effects; the incidence and severity of the side effects depend both on the patient and on the properties of the specific drug. The most common side effect in adults is drowsiness; cerebral stimulation may occur in infants. Other side effects include gastrointestinal irritation, headache, blurred vision, and dryness of the mouth. If a patient's condition does not improve after three days of treatment with antihistamines, it is unlikely that he will benefit from them. Antihistamines are readily absorbed from the alimentary tract, and most are rendered inactive by monoamine oxidase enzymes in the liver.

During the 1970s an H_2 -blocking agent, cimetidine (Tagamet) was introduced. Compounds of this class suppress histamine-induced gastric secretion and have proved useful in treating ulcers.

antiknock rating: *see* octane number.

Antilles, group of islands comprising all of the West Indies (*q.v.*) except the Bahamas. They are divided into two major groups: the Greater Antilles (*q.v.*), including Cuba, Hispaniola (Haiti and Dominican Republic), Jamaica, and Puerto Rico; and the Lesser Antilles, comprising all the rest of the islands.

The term Antilles dates traditionally from before Europeans discovered the New World, when Antilia referred to semimythical lands located somewhere west of Europe across the Atlantic. On medieval charts it was sometimes indicated as a continent or large island and sometimes as an archipelago. After discovery of the West Indies by Columbus, the Spanish term Antillas was commonly assigned to the new lands, and "Sea of the Antilles" in various European languages is an alternate name for the Caribbean Sea. Pop. (2000 est.) 36,443,000.

Antilles Current, branch of the Atlantic North Equatorial Current, forming part of the clockwise-setting ocean-current system in the North Atlantic Ocean. It flows northwestward along the north side of the Greater Antilles islands and merges with the Florida Current, which issues from the Gulf of Mexico through the Straits of Florida to form the initial portion of the Gulf Stream system.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Antiloehus, in Greek legend, son of Nestor, king of Pylos. One of the suitors of Helen, whose abduction caused the Trojan War, he accompanied his father to the war and distinguished himself as acting commander of the Pyliaans. When Nestor was attacked by Memnon (king of the Ethiopians), Antiloehus saved his father's life at the sacrifice of his own, thus fulfilling the oracle that had bidden him "beware of an Ethiopian." According to later accounts, he was slain by Hector or by Paris (both sons of King Priam of Troy) in the temple of the Thymbraean Apollo together with his friend Achilles.

Antim IVIREANUL: *see* Anthimus of Iberia.

antimacassar, protective covering thrown over the back of a chair or the head or cushions of a sofa, named after Macassar, a hair-oil in general use in the 19th century. The original antimacassars were made of stiff

Chairs with antimacassars, Palmer House, Chicago, 1875

By courtesy of the Library of Congress, Washington, D C

white crochet-work, but later soft, coloured materials, such as embroidered wools or silks, were used. In the 20th century the use of antimacassars largely died out.

Antimachus of Colophon (fl. c. 410 BC), a Greek poet and scholar who wrote a lengthy epic entitled *Thebais*, an account of the expedition of the Seven Against Thebes. His work was greatly admired in antiquity, and his pedantic style made him the model of the learned Alexandrian epic poets. The emperor Hadrian rated Antimachus above Homer, a judgment that did something to rescue him from obscurity. His work survives chiefly in the quotations cited by later writers to illustrate obscure words and out-of-the-way mythological detail.

antimatter, substance composed of atoms made up of elementary particles that have the mass and charge of electrons, protons, or neutrons, their counterparts in ordinary matter, but for which the charge is opposite in sign. Such particles are called positrons (e^+), antiprotons (\bar{p}), and antineutrons (\bar{n}), or, collectively, antiparticles. Matter and antimatter cannot coexist at close range for more than a small fraction of a second because they annihilate each other with release of large quantities of energy. It has been suggested that some distant galaxies may be composed entirely of antimatter.

The concept of antimatter first arose in analysis of the duality between positive and negative charge. The work of P.A.M. Dirac on the energy states of the electron led to the prediction and, finally, to laboratory production of a particle identical in every respect but one to the electron, that is, with positive instead of negative charge. Such a particle, called the positron (e^+), is not found in ordinary matter. The life expectancy or duration of the positron in ordinary matter is very short. Unless the positron is moving extremely fast, it will be drawn close to an ordinary electron by the attraction between opposite charges. A collision between the positron and electron results in their simultaneous disappearance, their masses being converted into energy in accordance with the Einstein relation $E = mc^2$, where c is the velocity of light. This process is called annihilation, and the resultant energy is emitted in the form of high-energy quanta of

electromagnetic radiation or gamma rays. The inverse reaction $\gamma \rightarrow e^+ + e^-$ can also proceed under appropriate conditions, and the process is called electron-positron creation. This last process is the one commonly used to produce positrons in the laboratory.

The electrical properties of antimatter are opposite to those of ordinary matter; thus, for example, the antiproton (\bar{p}) has a negative charge, and the antineutron (\bar{n}), although electrically neutral, has a magnetic moment opposite in sign to that of the neutron.

The Dirac theory of electrons and positrons predicts that an electron and a positron, because of Coulomb attraction, will bind together into an atom just as an electron and a proton form a hydrogen atom. The e^+e^- bound system is called positronium; its annihilation into gamma rays has been observed. Its lifetime is of the order of 10^{-7} second or 10^{-10} second, depending on the orientation of the two particles. These lifetimes agree well with those computed from Dirac's theory.

Both protons and neutrons are described by the Dirac equation. Antiprotons can be produced by bombarding protons with protons. If enough energy is available, that is, if the incident proton has a kinetic energy of at least 5.6 GeV (5.6×10^9 electron volts), extra particles of proton mass appear according to the formula $E = mc^2$. Such energies became available in the 1950s at the Berkeley (Calif.) Bevatron. In 1955 a team of physicists led by Owen Chamberlain and Emilio Segrè observed that antiprotons are produced by high-energy collisions. Antineutrons also were discovered at the Berkeley Bevatron by observing their annihilation in matter with a consequent release of high energies.

By the time the antiproton was discovered, a host of new subatomic particles had also been discovered; all these particles are now known to have corresponding antiparticles. Thus, there are positive and negative muons, positive and negative pions (also called π -mesons), the K-meson and the anti-K-meson, plus a long list of baryons and antibaryons. Most of these newly discovered particles have too short a lifetime for them to be able to combine with electrons. The exception is the positive muon that together with an electron has been observed to form a muonium atom.

In 1995 physicists at the European Laboratory for Particle Physics (CERN) created the first antiatom, the antimatter counterpart of an ordinary atom—in this case, antihydrogen, the simplest antiatom, consisting of a positron in orbit around an antiproton nucleus. They did so by firing antiprotons through a xenon gas jet. Some of the antiprotons collided with protons in the xenon nuclei, creating pairs of electrons and positrons; a few of the positrons thus produced then combined with the antiprotons to form antihydrogen. Each antiatom produced survived for only about forty-billionths of a second before it came into contact with ordinary matter and was annihilated.

Many attempts have been made to investigate the importance of antimatter in cosmological problems; theoretical and experimental knowledge of matter and antimatter is relevant to the understanding of the creation and constitution of the universe. Obviously no star can contain a close mixture of matter and antimatter; otherwise it would instantaneously explode with more violence than a supernova. Interstellar gas, and even intergalactic gas, cannot be a mixture, either. This is because among the annihilation products of proton plus antiproton into pions there is a certain amount of neutral pions (π^0), which in turn decay into two energetic gamma rays. Satellite experiments have not detected enough of such gamma rays to suggest a significant amount

of antimatter annihilation. One could resort to the hypothesis that matter and antimatter are separated on the scale of clusters of galaxies. The creation of baryon-antibaryon pairs, however, is very localized, the particle and antiparticle being created at distances of approximately 10^{11} centimetre. No present understanding of the evolution of the universe can explain the unmixing of matter and antimatter if they had been originally created together.

But the presence of large amounts of antimatter in the universe cannot be ruled out completely, nor can the possibility that some cosmic sources of intense radiation might be due to the interpenetration of matter and antimatter. But it can be shown that the total relative amount of antimatter in the Milky Way Galaxy must be less than one part in 10^7 .

Soon after the discovery of the antiproton the question was raised as to whether antimatter would be subject to gravitational attraction or repulsion from ordinary matter. This question is of extreme importance because gravitational repulsion between matter and antimatter is inconsistent with the theory of general relativity. The answers to such questions can be obtained experimentally because of the properties of K^0 and \bar{K}^0 mesons. Observation of the interference phenomena between K^0_1 and \bar{K}^0_2 led to the conclusion, by M.L. Good, that the gravitational interaction between matter and antimatter is identical to that between matter and matter.

antimer (chemistry): *see* enantiomorph.

Antimerina (people): *see* Merina.

antimetabolite, a substance that competes with, replaces, or inhibits a specific metabolite of a cell and thereby interferes with the cell's normal metabolic functioning. An antimetabolite is similar in structure to a metabolite, or enzymatic substrate, which is normally recognized and acted upon by an enzyme to form a substance required by the cell. Although the antimetabolite may resemble the substrate enough to be taken up by the cell, it does not react in the same way with the enzyme—either the enzymatic reaction is inhibited or the antimetabolite is converted by the enzyme into an aberrant component.

Many antimetabolites are used for therapeutic purposes. Sulfanilamides are antimetabolites that disrupt bacterial, but not human, metabolism and are used to eradicate bacterial infections in humans. Other antimetabolites such as methotrexate and 5-fluorouracil are used to treat a variety of cancers.

antimicrobial agent, any of a large variety of chemical compounds and physical agents that are used to destroy microorganisms or to prevent their development.

Antiseptics and germicides. The term antiseptic refers to agents applied to the living tissues of humans, other animals, and plants in order to destroy (bactericidal) or inhibit the growth (bacteriostatic) of infectious microorganisms. Antiseptics are used in medical practice to prevent or combat bacterial infections of superficial tissues and to sterilize instruments and infected material. A distinction must be made between antiseptics and chemotherapeutic agents, such as antibiotics and sulfonamides, which are administered by mouth or by injection for the treatment of internal or generalized infections but may also be applied locally in the treatment or prevention of superficial infections. (*See* antibiotic.)

Many chemical compounds can kill bacteria, but many of them also exhibit properties that limit or prohibit their use. Most antiseptics are general protoplasmic poisons and if used in sufficient concentration are harmful to the body's cells and tissues as well as to bacteria. Thus an antiseptic is most valuable in the disinfection of contaminated wounds or skin surfaces when there is a wide margin be-

tween its bactericidal and toxic concentrations. When, however, an antiseptic is to be used to disinfect contaminated instruments or other inanimate objects, its toxic properties are not important, and many compounds (called disinfectants) may be used that cannot be applied to living tissues. The term disinfectant thus refers to substances that are used to destroy microorganisms on inanimate surfaces—*e.g.*, surgical instruments, floors, and walls (*see* disinfectant). Antiseptics, disinfectants, and antibiotics are all germicides—*i.e.*, they are all substances that kill microorganisms.

The efficiency of an antiseptic must be measured in relation to three main factors: concentration, time, and temperature. It is desirable to know the minimum concentration at which an antiseptic will be effective. Some antiseptics such as phenol lose their activity sharply beyond a certain dilution, whereas mercurial preparations still inhibit bacterial growth at very high dilutions. Most antiseptics act more quickly under increased temperatures; the activity of coal-tar derivatives, for instance, is doubled by a rise in temperature from that of a cool room to body heat. Many antiseptics destroy certain types of microorganisms and not others. Many others will kill bacteria but not their spores, which are walled, usually dormant, reproductive bodies.

The Table gives the major families of antiseptics. Alcohols are among the most widely used antiseptics, especially ethyl and isopropyl alcohol, which are commonly used in a 70-percent concentration with water. They are also widely used in combination with other antiseptic agents. The phenols contain a large number of common antiseptics and disinfectants, among them phenol (carbolic acid) and creosote, while such bisphenols as hexyl resorcinol and hexachlorophene are widely used as antiseptic agents in soaps. Chlorine and iodine are both extremely effective agents and can be used in high dilution. Chlorine is widely used in the disinfection of drinking-water supplies, and among its derivatives, the hypochlorite solutions (*e.g.*, Dakin's solution) are used in surgical practice. Iodine is an effective disinfectant of wounds, particularly when used in an alcohol solution. The salts of most metals are generally too toxic to use on living tissues, but complex organic mercury salts (*e.g.*, mercurochrome, merthiolate) in alcohol solution are highly bacteriostatic and make useful wound disinfectants. The quaternary ammonium compounds are more widely used as disinfectants than as antiseptics. Certain acridine dyes are used as antiseptics, as are some aromatic, or essential, oils. Most acids and alkalis are either too caustic to tissues or are relatively inefficient bactericides.

Sterilization. Sterilization, which is any process, physical or chemical, that destroys all forms of life, is used especially to destroy microorganisms, spores, and viruses. Precisely defined, sterilization is the complete destruction of all microorganisms by a suitable chemical agent or by heat, either wet steam under pressure at 120°C (250°F) or more for at least 15 minutes, or dry heat at 160° to 180°C (320° to 360°F) for three hours.

Sanitization. A sanitizer is an agent, usually chemical in nature, that is used to reduce the number of microorganisms to a level that has been officially approved as safe. Sanitizers are commonly used to control bacterial levels in equipment and utensils found in dairies, other food-processing plants, eating and drinking establishments, and other places in which no specific pathogenic microorganisms are known to be present and destruction of all microorganisms may not be necessary.

Other antimicrobials. Preservatives, usually chemical agents, are added to certain foods and medicines to prevent the growth of microorganisms that may cause spoilage or disease. Prophylactics also are agents used to prevent infections and diseases. Vaccination is the ad-

Classification and survey of antiseptics and germicides

agent	approximate concentration used (percent)	mode of action	uses
Alcohols (e.g., ethyl alcohol)	50-70	denaturation of proteins; interference with metabolism; lysis (dissolving of organism)	as skin disinfectants; to form tinctures of antiseptics (used with acetone)
Cationic, surface-active quaternary ammonium compounds	0.1-0.25	denaturation of proteins; inactivation of cellular metabolites; dissolving of cell wall	as skin disinfectants and antiseptics; in sanitizing eating and drinking utensils, food-processing equipment
Bisphenols (2 phenols linked together)	2-5	inhibition of cell growth	as surgical scrubs (used with soaps and detergents); as deodorants
Chlorine gas and chloride compounds with available chlorine	0.0000002-0.000002	liberation of cell constituents	in chlorination of water supplies; as food-plant sanitizer; in treating wounds and hospital equipment
Iodine and iodized compounds	2-16	precipitation of cell proteins	in ointment and salves as skin antiseptics; in surgical-instrument disinfection
Aldehydes (e.g., formaldehyde)	1-5	general microorganism poison	in disinfection of dwellings, ships, storage houses, utensils, clothing; in hospital-instrument sterilization
Mercurials (inorganic and organic)	0.001-1	precipitation of cell proteins; destruction of enzymes	as skin antiseptic in skin ointments and salves; as preservatives for drugs
Oligodynamic metals (silver, copper, mercury)	traces	cell-membrane destruction; coagulation of cell materials	as disinfectants; in ointments and salves; in cement (e.g., in shower rooms)
Heavy metals	0.1-1	precipitation of cell proteins	in cosmetics and deodorants; antiperspirants; skin antiseptics
Acids	0.1-5	precipitation of cell proteins; destruction of cell wall	as skin antiseptics (salicylic benzoic acids); in food preservatives (benzoic acid)
Dyes (e.g., acridine)	0.1-1	inhibition of cell function; combination with essential metabolites	in dentistry as mucous antiseptics; in laboratory media to inhibit growth of unwanted bacteria
Antibiotics and chemotherapeutic drugs (e.g., penicillin, sulfonamides)	0.001-1	interference with cell metabolism; synergistic action in body to counteract infection	in chemotherapy of disease; in ointment and salves as skin antiseptics
Coal-tar derivatives (e.g., phenol, cresols)	0.1-5	cytoplasmic poisons; disruption of cell wall; precipitation of proteins; inactivation of enzymes	as skin antiseptics in dilute solutions; as floor and wall disinfectants, combined with soaps; as surgical-instrument sterilizers
Aromatic oils (especially pine oil)	0.1-5	effect on cell constituents; mechanical effect inhibits cell growth	as disinfectants with soaps for washing floors and walls; as a deodorant on inanimate surfaces

ministration of harmless amounts of disease-causing microorganisms into animals, including humans, to prevent diseases. (See vaccine.) Sterile filtration usually removes large microorganisms (e.g., bacteria, fungi, and their spores) from heat-sensitive solutions, but this physical method does not effectively remove small infectious microorganisms (e.g., filterable viruses and rickettsias).

Modes of action. Some antiseptics, such as alcohols and quaternary ammonium compounds, act directly on microbial cells to dissolve them. Others may penetrate the cells and cause the release of amino acids, nuclear material, and other important chemical constituents. Some compounds penetrate microbial cell walls and inactivate essential membrane transport systems, so that the cells can no longer obtain the nutrients necessary for them to survive and to reproduce. Others coagulate certain vital materials in cells, thereby destroying the microorganisms. A few agents disrupt the metabolism of the cells, so that they can no longer assimilate nutrients; as a result, the cells starve and die.

antimonide, any member of a rare mineral group consisting of compounds of one or more metals with antimony (Sb). The coordination of the metal is virtually always octahedral or tetrahedral; i.e., in the former, each metal ion occupies a position within an octahedron composed of six negatively charged antimony ions, whereas, in the latter, the metal ion is surrounded by four negatively charged neighbours that are arranged tetrahedrally. The crystal structure of octahedral coordination is identical to that of the sulfide mineral galena; that of tetrahedral coordination corresponds to the structure of another member of the same mineral group, argentite.

Two common antimonides are dyscrasite (Ag_3Sb) and stibiopalladinite (Pd_3Sb_2). Dyscrasite exhibits a distinct orthorhombic symmetry. It is an important silver ore that occurs in deposits of hydrothermal origin associated with intrusive igneous rocks; significant amounts are found at Cobalt, Ont., Can., and at Broken Hill, N.S.W., Australia. Stibiopalladinite exhibits trigonal symmetry. It is a principal palladium mineral that occurs in

various deposits associated with platinum, pyrrhotite, and chalcopyrite. It has been found in the Bushveld Complex, S.Af., at Kamalalda, W.Aus., and at Norilsk, Russia. Other antimonides include aurostibite (AuSb_2) and breithauptite (NiSb).

All antimonides have a metallic lustre, are opaque, and have high specific gravity and intermediate to low hardness.

antimony (Sb, from Latin *stibium*), a metallic element belonging to the nitrogen family (Group Va of the periodic table). Antimony exists in many allotropic forms (physically distinct conditions that result from different arrangements of the same atoms in molecules or crystals).

A brief treatment of antimony follows. For full treatment, see MACROPAEDIA: Chemical Elements: *Nitrogen group elements*.

Antimony is a lustrous, silvery, bluish white solid that is very brittle and has a flaky texture. It occurs chiefly as the gray sulfide mineral stibnite (Sb_2S_3). One method of obtaining antimony from stibnite is by roasting the ore to form the oxide Sb_2O_3 , which is then reduced to the element by heating it with carbon. Another is to melt the ore with scrap iron in a furnace; as the iron combines with the sulfur to form a liquid layer of molten iron sulfide, the heavier liquid antimony settles to the bottom and is drawn off.

Because it is a poor conductor of heat and electricity, antimony tarnishes only slightly in dry air, but it is gradually converted to an oxide if the air is moist. When it is heated in air, it burns with a brilliant blue flame and gives off white fumes of the trioxide Sb_2O_3 . The trioxide of antimony is soluble in either acids or alkalis.

In its pure state antimony has no important uses, but, when combined physically or chemically with other substances, it is an extremely useful metal. Because some antimony alloys expand on solidifying (a rare characteristic that they share with water), they are particularly valuable as castings and type metal; the expansion of the alloy forces the metal to fill the small crevices of casting molds. Moreover, the presence of antimony in type metal, which also includes lead and small amounts of tin, increases the hardness of the type and gives it a sharp definition. Even when added in minor quantities, antimony imparts strength and hardness to other metals, particularly lead, with which it forms alloys used in plates of

Stibnite, the primary mineral from which antimony is obtained; specimen from Prince William, New Brunswick, Can.

automobile storage batteries, in bullets, and in coverings for cables. Combined with tin and lead, antimony forms antifriction alloys called babbitt metals that are used as components of machine bearings.

Antimony compounds (especially the trioxide) are widely used as flame retardants in paints, plastics, rubber, and textiles. Several other antimony compounds are used as paint

pigments: tartar emetic (an organic salt of antimony) is used in the textile industry to aid in binding certain dyes to fabrics and in medicine as an expectorant and a nauseant.

atomic number	51
atomic weight	121.75
melting point	630.5° C (1,166.9° F)

antimony poisoning, harmful effects upon body tissues and functions of ingesting or inhaling certain compounds of antimony. Such poisoning resembles arsenic poisoning.

Antimony poisoning has resulted from drinking acidic fruit juices containing antimony oxide dissolved from the glaze of cheap enamelware containers. Toxicity can also result from repeated exposure to antimony in medications, such as tartar emetic (antimony and potassium tartrate), used to induce vomiting and in treatment of helminthic and fungal infestations. The industrial use of antimony has not appeared to be associated with serious occupational poisoning. It is believed that the toxicity of antimony and of arsenic is due to the fact that in combination with enzymes (the organic catalysts of the cell) they interfere with cellular metabolism.

Antimorona (people): *see* Antaimoro.

antimycotic: *see* fungicide.

Antin, Mary (b. 1881, Polotsk, Russia—d. May 15, 1949, Suffern, N.Y., U.S.), author of the autobiographical *Promised Land* and other books on immigrant life in the United States.

Antin emigrated to the United States in 1894 and attended Teachers College of Columbia University and Barnard College, New York City, 1901–04. She wrote (in Yiddish) about her voyage to the United States in her first book, *From Polotsk to Boston* (Eng. trans., 1899). *The Promised Land* (1912), which first appeared as a serial in *The Atlantic Monthly* and won wide acclaim, narrates the experiences of European Jews and the contrast with life in the United States. After its publication she toured the United States as a lecturer. Her third book on immigrants, *They Who Knock at Our Gates*, was published in 1914.

antineutrino, subatomic particle that is the antimatter counterpart of the neutrino (*q.v.*).

antineutron, antiparticle of the ordinary neutron, first produced in 1956 at the University of California (Berkeley) by passing an antiproton beam through matter. Antineutrons were detected along with neutrons after antiprotons in the beam exchanged their negative charge with nearby protons, which have a positive charge. Antineutrons are quickly annihilated by neutrons or protons.

antinomianism (Greek *anti*, “against”; *nomos*, “law”), doctrine according to which Christians are freed by grace from the necessity of obeying the Mosaic Law. The antinomians rejected the very notion of obedience as legalistic; to them the good life flowed from the inner working of the Holy Spirit. In this circumstance they appealed not only to Martin Luther but also to Paul and Augustine.

The ideas of antinomianism had been present in the early church, and some Gnostic heretics believed that freedom from law meant freedom for license. The doctrine of antinomianism, however, grew out of the Protestant controversies on the law and the gospel and was first attributed to Luther’s collaborator, Johann Agricola. It also appeared in the Reformed branch of Protestantism. The left-wing

Anabaptists were accused of antinomianism, both for theological reasons and also because they opposed the cooperation of church and state, which was considered necessary for law and order. For similar reasons, in the 17th century, Separatists, Familists, Ranters, and Independents in England were called antinomians by the established churches. In New England, Anne Hutchinson was accused of the doctrine when she said that the churches were preaching “the covenant of works.” The Evangelical movement at the end of the 18th century produced its own antinomians who claimed an inner experience and a “new life,” which they considered the true source of good works.

antinomy, in philosophy, contradiction, real or apparent, between two principles or conclusions, both of which seem equally justified; it is nearly synonymous with the term paradox. Immanuel Kant, the father of critical philosophy, in order to show the inadequacy of pure reason in the field of metaphysics, employed the word antinomies in elaborating his doctrine that pure reason generates contradictions in seeking to grasp the unconditional. He offered alleged proofs of the two propositions that the universe had a beginning and is of finite extent (the thesis) and also of a contrary proposition (the antithesis). Similarly, he offered proofs both for and against the three propositions: (1) that every complex substance consists of simple parts; (2) that not every phenomenon has a sufficient “natural” cause (*i.e.*, that there is freedom in the universe); and (3) that there exists a necessary being, either within or outside the universe. Kant used the first two antinomies to infer that space and time constitute a framework imposed, in a sense, by the mind. Kant’s “Copernican Revolution” was that things revolve around the knower, rather than the knower around things. He resolved the four antinomies by drawing a distinction between phenomena (things as they are known or experienced by the senses) and noumena (things in themselves; *see* noumenon). Kant insisted that we can never know the noumena, for we can never get beyond phenomena.

In the 20th century more specific suggestions for resolving the antinomies arose. Because the philosophical significance of these possible resolutions continues to be debated, however, the force of Kant’s case against pure reason is yet to be assessed.

Antinoöpolis, modern SHEIKH ABADE, Roman city in ancient Egypt, on the east bank of the Nile, 24 miles (37 kilometres) south of modern al-Minyā in al-Minyā *muhāfazah* (governorate). On the site of a Ramesside temple, the Roman emperor Hadrian officially founded the city Oct. 30, AD 130, naming it after his companion Antinoüs, who had drowned in the Nile near the site earlier that year. The Via Hadriana, which led to the Red Sea, began at Antinoöpolis. Papyri found there have provided information about its constitution, based on that of Naukratis. The citizens were considered Greeks, though they could marry Egyptian women. The city survived at least to the 8th century AD.

Antinoüs (b. c. 110, Bithynium, Bithynia—d. 130, near Besa, Egypt), favourite of the Roman emperor Hadrian, who was deified by the Emperor after his death. Antinoüs, with whom Hadrian had a homosexual relationship, accompanied him on his many journeys throughout the Mediterranean world. While the two were visiting Egypt, Antinoüs drowned in the Nile. Hadrian erected temples to him all over the empire and founded a city, named Antinoöpolis in his honour, near the place of his death. Many sculptures, gems, and coins survive depicting Antinoüs as a model of youthful beauty.

antinovel, also called NOUVEAU ROMAN (French: “new novel”), avant-garde novel of

the mid-20th century marking a radical departure from the conventions of the traditional novel. Starting from the premise that everything in the novel had been done—that whole societies had been portrayed in panorama and individual psychologies probed minutely—the antinovelists sought new avenues of fictional exploration. In their efforts to overcome literary habits and to challenge the expectations of their readers, they deliberately frustrated conventional literary expectations, avoiding any expression of the author’s personality, preferences, or values. They rejected the traditional elements of character, entertainment, dramatic progress, and dialogue that reveal character or further plot.

The term antinovel was first used by Jean-Paul Sartre in an introduction to Nathalie Sarraute’s *Portrait d’un inconnu* (1948; *Portrait of a Man Unknown*, 1958). It is usually associated with the French *nouveau roman* of the 1950s and ‘60s, but works of other writers, such as the German novelist Uwe Johnson’s *Mutmassungen über Jakob* (1959; *Speculations About Jakob*, 1963), also reveal vaguely identified characters, casual arrangement of events, and uncertainty of meaning.

Antioch, also called ANTIOCH PISIDIAN, Greek ANTIOCHEIA PISIDIAS, ancient city in Phrygia, near the Pisidian border, close to modern Yalvaç, in Isparta *il* (province), Turkey. Founded by Seleucus I (c. 358–281 BC), it was made a free city in 189 BC by the Romans, who took direct control in c. 25 BC; soon thereafter the emperor Augustus made it a colony with the name Caesarea Antiochia. It became the centre of civil and military administration in southern Galatia, and in the time of the emperor Claudius I (reigned AD 41–54), St. Paul made it one of the centres of his mission in that province. Antioch was finally assigned to Pisidia under Diocletian’s provincial reorganization. Its ruins include a large rock cutting which may have held the temple of Men Ascaënus, the local Phrygian deity.

Antioch, Turkish ANTAKYA, populous city of ancient Syria, since 1939 the chief town of the *il* (province) of Hatay in southern Turkey, near the mouth of the Orontes River (Turkish Asi Nehri). It was founded in 300 BC by the Greeks and was the centre of the Seleucid Kingdom until 64 BC, when the Romans made it the capital of their province of Syria. The city was one of the earliest centres of Christianity, serving as the headquarters of the missionary St. Paul in about AD 47–55. Antioch prospered in the 4th and 5th centuries

The Four Seasons (corner panels) and mythological scenes, mosaic floor of the House of the Red Pavement, Antioch, c. 5th century AD

By courtesy of the Department of Art and Archaeology, Princeton University

from nearby olive plantations and in the 6th century developed a silk industry. That century also brought a series of earthquakes and fires. Antioch was captured temporarily by the Persians in 540 and 611 and was absorbed into the Arab caliphate in 637. Under the Arabs, it shrank to the status of a small town. The Byzantines recaptured the city in 969, and it served as a frontier fortification until taken by the Seljuq Turks in 1084. In 1098 it was captured by the crusaders and was taken by the Mamlūks in 1268. It finally fell to the Ottoman Turks in 1517 and remained under Ottoman control until World War I.

The activities of the modern town are based mainly on the agricultural produce of the adjacent area, including the intensively cultivated Amik plain. The chief crops are wheat, cotton, grapes, rice, olives, vegetables, and fruit. The town has soap and olive-oil factories and cotton ginning and other processing industries. Silk, shoes, and knives are also manufactured. Important archaeological discoveries have been made there. Pop. (1985) 107,821.

Antioch, a principality centred on the city of Antioch, founded by European Christians in territory taken from the Muslims in 1098, during the First Crusade. It survived as a European outpost in the East for nearly two centuries.

Antioch's territory included the well-fortified, predominantly Christian city, the leading commercial centre of the Latin East, and an area that stretched north into Cilicia, east to the frontiers of Edessa and Aleppo, and south into central Syria. Its first prince, Bohemond I (reigned 1098–1111), and regents, Tancred (1104–12) and Roger, prince of Antioch (regent from 1112 to 1119), were successful in their attempts to expand the state, but the Muslims thwarted their campaigns to conquer Aleppo. Antioch's princes often died in battle, leaving heirs too young to rule; succession disputes were frequent, and the king of Jerusalem, the princes' feudal overlord, often intervened to restore order.

The state prospered economically despite domestic unrest and Muslim onslaughts. Because trade was vital to Christian and Muslim alike, agreements were reached that enabled trade to continue despite religious differences. Spices, dyes, silk, and porcelain came on caravans from the East and were shipped to European markets. Nearby orchards and olive groves supplied sweet lemons and olive oil for export, and wood from the forests of Lebanon was traded to the Egyptians in return for fine cloth.

In 1187 Bohemond III (reigned 1163–1201) of Antioch obtained guarantees for the principality from the Muslim leader Saladin (reigned 1169–93), after Saladin had conquered a large part of the kingdom of Jerusalem. After Bohemond's death, Antioch was torn by wars over the succession, and, though peace was restored, these disputes gave the Muslims time to gather their forces. By 1268 Antioch's territory had been severely diminished, and the city itself surrendered to the attacking army of Baybars I (1260–77), Mamlūk sultan of Egypt and Syria.

Antioch, Council of (AD 341), a non-ecumenical Christian church council held at Antioch (modern Antakya in southeastern Turkey) on the occasion of the consecration of the emperor Constantine I's Golden Church there. It was the first of several 4th-century councils that attempted to replace orthodox Nicene theology with a modified Arianism (*q.v.*). Attended by the Eastern emperor Constantius II and about 100 Eastern bishops, the council developed four creeds as substitutes for the Nicene, all of them to some degree unorthodox and omitting or rejecting the Nicene statement that Christ was "of one substance" (*homoousios*) with the Father. The disciplinary 25 canons of Antioch are gener-

ally thought to have come from this council, but some scholars believe they were the work of an earlier council (330) at Antioch.

Antioch, Orthodox Church of: *see* Greek Orthodox Patriarchate of Antioch and All the East.

Antioch, School of, Christian theological institution in Syria, traditionally founded in about AD 200, that stressed the literal interpretation of the Bible and the completeness of Christ's humanity, in opposition to the School of Alexandria (*see* Alexandria, School of), which emphasized the allegorical interpretation of the Bible and stressed Christ's divinity. Flourishing in the 4th–6th century, the School of Antioch produced several significant theologians, including Diodore of Tarsus, Theodore of Mopsuestia, St. John Chrysostom, and Theodoret of Cyrillus.

Antioch University, private coeducational institution of higher learning founded in 1852 as Antioch College in Yellow Springs, Ohio, U.S. It is noted for its experimental curricula and work-study programs. Horace Mann was its first president from 1852 until his death in 1859.

Although the college from its outset was co-educational, nonsectarian, and committed to equal opportunity for blacks, its real innovations began in 1921 when its president, Arthur E. Morgan, undertook what has been called the first progressive venture of consequence in higher education, an attempt to combine "a liberal college education, vocational training, and apprenticeship for life." Students were required to alternate their time between traditional subjects and full-time jobs, to give them experience of "actual living in actual society." Antioch conducts cooperative and work-experience programs in many U.S. states and in foreign countries. The school has branches throughout the United States that offer liberal-arts courses of study. Antioch also has several specialized centres, including the School of Law in Washington, D.C., and the New England Graduate School (a teacher-training school) in Keene, N.H. Antioch International has centres in England and Germany. In 1978 Antioch consolidated all its programs and adopted the name Antioch University.

Antiochene rite, also called WEST SYRIAN RITE, the system of liturgical practices and discipline observed by Syrian Monophysites (Jacobites), the Malabar Christians of Kerala, India (Jacobites), and three Eastern-rite communities of the Roman Catholic church: Catholic Syrians, Maronites, and Malankarese Christians of Kerala. The Antiochene rite is sometimes called the West Syrian rite to distinguish it from the Chaldean, or East Syrian, rite.

The Antiochene rite, which served as the earliest model for almost all Eastern rites, originated in the patriarchate of Antioch and later generated the Byzantine and Alexandrian rites. The Liturgy of St. James evolved from the Jerusalem–Antioch liturgy and is currently used in modified form by both Catholic and Jacobite Syrians and Maronites.

Antiochus, name of kings of the Seleucid kingdom of Syria, grouped below chronologically and indicated by the symbol ●.

● **Antiochus I SOTER** (b. 324 BC—d. 262/261), king of the Seleucid kingdom of Syria, who ruled about 292–281 BC in the east and 281–261 over the whole kingdom. Under great external pressures, he consolidated his kingdom and encouraged the founding of cities.

Antiochus was the son of Seleucus I, founder of the Seleucid kingdom, and his Sogdian queen, Apama. When an invasion of nomads threatened the eastern possessions of his father's realm (between the Caspian and Aral seas and the Indian Ocean), Antiochus was appointed king (292). He restored some of the

damage caused by the invaders and rebuilt three cities. Because his father still had interest in expanding the eastern trade, Antiochus dispatched a noted geographer and general to explore the environs of the Caspian Sea.

After his father's assassination in 281, Antiochus succeeded to the entire realm, but he was immediately beset by revolts in Syria (probably instigated by Egypt), by independence movements in northern Anatolia, and by a war led by Antigonos II Gonatas, ruler of the Greek cities and Macedonia. In 279, after the Gauls invaded Greece and almost ruined Antigonos, he and Antiochus signed a pact promising not to interfere with one another's territory. The next year, however, 20,000 Gauls crossed into Asia Minor, and the independent states in the northern part recruited them to harass Antiochus. He was preoccupied with the pacification of Syria until 275, when, utilizing Indian elephants brought from the east, he defeated the Gauls, who were afterward settled by their allies in Phrygia to make it a buffer state. The Ionian city-states that Antiochus had spared from the Gauls' ravages hailed him as a god and named him Soter ("Saviour"). In 275 the alliance with Antigonos, now fully in possession of Macedonia, was cemented by marriage to Antiochus' half sister.

Following the Gallic incursions in Greece, Antiochus encouraged Greek immigration to his realm and established many new cities in Asia Minor to serve as counterweights to the Gauls. He built other cities in Iran to forestall the Parthian threat to his eastern frontier, and he probably fostered a revival of Babylonian culture and religion to counteract Persian influence. At Babylon he rebuilt the ancient Esagila shrine, although he moved the city's populace to a great Seleucid city a short distance away on the Tigris River.

The aggressions of Ptolemy II of Egypt caused continuous friction with Antiochus. In 279 he lost Miletus, in southwestern Asia Minor, and in 276 the Egyptians invaded northern Syria. But Antiochus defeated his opponent, repelled him, and secured an alliance with the Egyptian ruler's half brother who ruled Cyrene. After Ptolemy married the energetic Arsinoe II, however, the war turned against the Seleucids, and about 273–272, Phoenicia and the coast of Asia Minor were lost to Egypt.

The continuous troubles in the west caused Seleucid control in the far eastern part of the empire to weaken. In 280 Antiochus made his eldest son king in the east, but he proved incompetent. Between 266 and 261 Antiochus was drawn into a war with Pergamum, and in 262 he suffered a defeat and lost additional territory. Soon afterward he died, leaving his son Antiochus II as successor.

BIBLIOGRAPHY. The primary source in English of knowledge about the members of the Seleucid dynasty is Edwin Robert Beran, *The House of Seleucus*, 2 vol. (1902, reprinted 1966).

● **Antiochus II THEOS** (b. c. 287 BC—d. 246), king of the Seleucid dominions in the Middle East, who succeeded his father, Antiochus I, in 261 BC and spent much of his reign at war with Egypt, recovering much territory in Anatolia.

Finding a willing ally in Antigonos, ruler of Macedonia, who had suffered at the hands of Ptolemy II of Egypt, Antiochus waged the Second Syrian War (259–255) against Ptolemy to avenge his father's losses. While Antigonos defeated the Egyptian fleet at sea, Antiochus reconquered much of Anatolia, including the cities of Miletus and Ephesus, and also the Phoenician coast.

In Miletus, Antiochus overthrew a tyrant after he recaptured the city, and the citizens worshiped him as a god in thanksgiving. He

later organized an empire-wide cult, as suggested by his epithet, Theos (God). He also established the freedom of the other Ionian cities. Further, he continued his predecessors' policies of encouraging the foundation of cities in his realm.

For unknown reasons, around 253, Antiochus dismissed his first queen, Laodice, and married Ptolemy's daughter Berenice. At his death in 246, a civil war erupted between the two queens. He was succeeded by his son Seleucus II, while another son, Antiochus Hierax, established himself in western Anatolia.

The primary source in English of knowledge about the members of the Seleucid dynasty is Edwin Robert Bevan's *The House of Seleucus*, 2 vol. (1902; reprinted 1966).

• **Antiochus III**, byname ANTIQCHUS THE GREAT, Greek ANTIQCHUS MEGAS (b. 242 BC—d. 187, near Susa, Iran), Seleucid king of the Hellenistic Syrian Empire from 223 BC to 187, who rebuilt the empire in the East but failed in his attempt to challenge Roman ascendancy in Europe and Asia Minor. He reformed the empire administratively by reducing the provinces in size, established a ruler cult (with himself and his consort Laodice as divine), and improved relations with neighbouring countries by giving his daughters in marriage to their princes.

Antiochus III, coin, late 3rd–early 2nd century BC; in the British Museum

The son of Seleucus II, Antiochus succeeded his brother Seleucus III as king. He retained from the previous administration Hermias as chief minister, Achaeus as governor of Asia Minor, and Molon and his brother Alexander as governors of the eastern provinces, Media and Persis. In the following year, when Molon rebelled and assumed the title of king, Antiochus abandoned a campaign against Egypt for the conquest of southern Syria, on the advice of Hermias, and marched against Molon, defeating him in 220 BC on the far bank of the Tigris and also conquering Atropatene, the northwestern part of Media. Shortly thereafter he had Hermias killed and was thus rid of most of the influences from the previous administration. In the same year, Achaeus set himself up as king in Asia Minor, but a mutiny in his army kept him from attacking Antiochus.

Antiochus was now free to conduct what has been called the Fourth Syrian War (219–216), during which he gained control of the important eastern Mediterranean sea ports of Seleucia-in-Pieria, Tyre, and Ptolemais. In 218 he held Coele Syria (Lebanon), Palestine, and Phoenicia. In 217 he engaged an army (numbering 75,000) of Ptolemy IV Philopator, a pharaoh of the Hellenistic dynasty ruling Egypt, at Raphia, the southernmost city in Syria. His own troops numbered 68,000. Though he succeeded in routing the left wing of the Egyptian army, his phalanx (heavily armed infantry in close ranks) in the centre was defeated by a newly formed Egyptian

phalanx. In the subsequent peace settlement, Antiochus gave up all his conquests except the city of Seleucia-in-Pieria.

After the Syrian war, he proceeded against the rebel Achaeus. In alliance with Attalus I of Pergamum, Antiochus captured Achaeus in 213 in his capital, Sardis, and had him executed in a barbaric manner. After the pacification of Asia Minor he entered upon his later to be famous eastward campaign (212–205), pressing forward as far as India. In 212 he gave his sister Antiochis in marriage to King Xerxes of Armenia, who acknowledged his suzerainty and paid him tribute. He occupied Hecatompylos (southeast of the Caspian Sea), the capital of the Parthian king Arsaces III, and forced him to enter into an alliance in 209 and the following year defeated Euthydemus of Bactria, though he allowed him to continue to rule and retain his royal title. In 206 he marched across the Hindu Kush into the Kābul Valley and renewed a friendship with the Indian king Sophagasenos.

Returning westward via the Iranian provinces of Arachosia, Drangiana, and Carmania, he arrived in Persis in 205 and received tribute of 500 talents of silver from the citizens of Gerha, a mercantile state on the east coast of the Persian Gulf. Having established a magnificent system of vassal states in the East, Antiochus now adopted the ancient Achaemenid title of "great king," and the Greeks, comparing him to Alexander the Great, surnamed him also "the Great."

After the death of Ptolemy IV, Antiochus concluded a secret treaty with Philip V, ruler of the Hellenistic kingdom of Macedonia, in which the two plotted the division of the Ptolemaic empire outside Egypt. Antiochus' share was to be southern Syria, Lycia, Cilicia, and Cyprus; Philip was to have western Asia Minor and the Cyclades. Antiochus invaded Coele Syria, defeated the Ptolemaic general Scopas at Panion near the source of the Jordan River in the year 200, gained control of Palestine, and granted special rights to the Jewish temple state. But Philip, marching along the Dardanelles, became involved in a war with Rhodes and Pergamum, both of whom appealed to Rome for help against Macedonia, informing Rome of the alliance between the two Hellenistic kings. Rome intervened decisively in the system of Hellenistic states. Philip was defeated by the Romans in the Second Macedonian War (200–196), and Antiochus refused to help him. Instead, taking advantage of the Romans' involvement with Philip, Antiochus marched against Egypt. Though the Romans had sent ambassadors to Ptolemy V, they could not lend him any serious assistance. When peace was concluded in 195, Antiochus came permanently into possession of southern Syria—which had been fought over for 100 years by the Ptolemies and Seleucids—and of the Egyptian territories in Asia Minor. He also gave his daughter Cleopatra in marriage to Ptolemy V. Egypt practically became a Seleucid protectorate.

In his insatiable expansionist drive, Antiochus occupied parts of the kingdom of Pergamum in 198 and in 197 Greek cities in Asia Minor. In 196 BC he crossed the Hellespont into Thrace, where he claimed sovereignty over territory that had been won by Seleucus I in the year 281 BC. A war of harassment and diplomacy with Rome ensued. A number of times the Romans sent ambassadors demanding that Antiochus stay out of Europe and set free all the autonomous communities in Asia Minor. To meet these demands would have meant the actual dissolution of the western part of the Seleucid Empire, and Antiochus thus refused. Tensions with Rome increased further when the great Carthaginian general Hannibal, who had fled from Carthage in the aftermath of defeat by the Romans in the Second Punic War, found refuge with Antiochus in 195 BC and became his adviser.

Antiochus offered an alliance to Philip of Macedonia, whom he had previously forsaken, but was rebuffed. Philip, Rhodes, Pergamum, and the Achaean League joined Rome. Only the Aetolians, discontent with Rome's growing influence in Greece, called upon Antiochus to be their liberator and appointed him commander in chief of their league. Relying on them Antiochus landed in Demetrias in the autumn of 192 with only 10,500 men and occupied Euboea. But he found little support in central Greece. In 191 the Romans, numbering more than 20,000, cut him off from his reinforcements in Thrace and outflanked his position at the pass of Thermopylae (in Greece). With the remainder of his troops Antiochus fled to Chalcis on Euboea and from there by sea to Ephesus; his fleet was wiped out by the combined naval forces of Rome, Rhodes, and Pergamum. Meeting no resistance, the Roman army crossed the Hellespont in 190. Antiochus was now eager to negotiate on the basis of Rome's previous demands, but the Romans insisted that he first evacuate the region west of the Taurus Mountains. When Antiochus refused, he was decisively defeated in the Battle of Magnesia near Mt. Sipylus, where he fought with a heterogeneous army of 70,000 men against an army of 30,000 Romans and their allies. Although he could have continued the war in the eastern provinces, he renounced all claim to his conquests in Europe and in Asia Minor west of the Taurus at the peace treaty of Apamea. He also was obliged to pay an indemnity of 15,000 talents over a period of 12 years, surrender hostages, including his son Antiochus IV. His kingdom was now reduced to Syria, Mesopotamia, and western Iran. In 187 Antiochus was murdered in a Baal temple near Susa, where he was exacting tribute in order to obtain much needed revenue.

Bengtson, *Die Strategie in der hellenistischen Zeit*, vol. 2 (1944), delineates his administrative reforms; G.M.A. Richter, *The Portraits of the Greeks*, vol. 3 (1965), discusses the preserved portrait of Antiochus.

• **Antiochus IV EPIPHANES** (God Manifest), also called ANTIQCHUS EPIMANES (the Mad) (b. c. 215 BC—d. 164, Tabae, Iran), Seleucid king of the Hellenistic Syrian kingdom who reigned from 175 to 164 BC. As a ruler he was best known for his encouragement of Greek culture and institutions. His attempts to suppress Judaism brought on the Wars of the Maccabees.

Early career. Antiochus was the third son of Antiochus III the Great. After his father's defeat by the Romans in 190–189, he served as hostage for his father in Rome from 189 to 175, where he learned to admire Roman institutions and policies. His brother, King Seleucus IV, exchanged him for Demetrius, the son of Seleucus; and after Seleucus was murdered by Heliodorus, a usurper, Antiochus in turn ousted him. During this period of uncertainty in Syria, the guardians of Ptolemy VI, the Egyptian ruler, laid claim to Coele Syria, Palestine, and Phoenicia, which Antiochus III had conquered. Both the Syrian and Egyptian parties appealed to Rome for help, but the Senate refused to take sides. In 173 Antiochus paid the remainder of the war indemnity that

had been imposed by the Romans on Antiochus III at the Treaty of Apamea (188).

Antiochus forestalled an Egyptian expedition to Palestine by invading Egypt. He defeated the Egyptians between Pelusium and Mount Kasion, conquered Pelusium, and in 169 occupied Egypt with the exception of Alexandria, the capital. Ptolemy VI was Antiochus' nephew—Antiochus' sister, Cleopatra I, had married Ptolemy V—and Antiochus contented himself with ruling Egypt as Ptolemy's guardian, giving Rome no excuse for intervention. The citizens of Alexandria, however, appealed to Ptolemy VIII, the brother of Ptolemy VI, and to his sister Cleopatra II to form a rival government. Disturbances in Palestine forced Antiochus to return to Syria, but he safeguarded his access to Egypt with a strong garrison in Pelusium.

In the winter of 169/168 Perseus of Macedonia in vain begged Antiochus to join forces with him against the danger that Rome presented to all of the Hellenistic monarchs. In Egypt, Ptolemy VI made common cause with his brother and sister and sent a renewed request to Rome for aid, and Antiochus prepared for battle. The fleet of Antiochus won a victory at Cyprus, whose governor surrendered the island to him. Antiochus invaded Egypt again in 168, demanded that Cyprus and Pelusium be ceded to him, occupied Lower Egypt, and camped outside Alexandria. The cause of the Ptolemaeans seemed lost. But on June 22, 168, the Romans defeated Perseus and his Macedonians at Pydna, and there deprived Antiochus of the benefits of his victory. In Eleusis, a suburb of Alexandria, the Roman ambassador, Gaius Popillius Laenas, presented Antiochus with the ultimatum that he evacuate Egypt and Cyprus immediately. Antiochus, taken by surprise, asked for time to consider. Popillius, however, drew a circle in the earth around the king with his walking stick and demanded an unequivocal answer before Antiochus left the circle. Dismayed by this public humiliation, the king quickly agreed to comply. Roman intervention had reestablished the status quo. By being allowed to retain southern Syria, to which Egypt had laid claim, Antiochus was able to preserve the territorial integrity of his realm.

Efforts to hellenize the kingdom. Both economically and socially he made efforts to strengthen his kingdom—inhabited in the main by Orientals (non-Greeks of Asia Minor and Persia)—by founding and fostering Greek cities. Even before he had begun his reign he had contributed to the building of the temple of Zeus in Athens and to the adornment of the theatre. He enlarged Antioch on the Orontes by adding a section to the city (named Epiphania after him). There he built an aqueduct, a council hall, a marketplace, and a temple to Jupiter Capitolinus. Babylon, which revered him as Soter (Liberator, or Saviour) of Asia, was given a Greek colony that was granted freedom of the city. Another Epiphania was founded in Armenia. Ecbatana (in Persia) was also named Epiphania and became a Greek city. Many of these cities were granted the right to coin their own municipal currency. The mint of Antioch on the Persian Gulf served the trade along the sea route between India and the district at the mouth of the great Mesopotamian rivers.

Antiochus' hellenizing policies brought him into conflict with the prosperous Oriental temple organizations, and particularly with the Jews. Since Antiochus III's reign the Jews had enjoyed extensive autonomy under their high priest. They were divided into two parties, the orthodox Hasideans (Pious Ones) and a reform party that favoured Hellenism. For financial reasons Antiochus supported the reform party and, in return for a considerable sum, permitted the high priest, Jason, to build a gymnasium in Jerusalem and to introduce the Greek mode of educating young people.

In 172, for an even bigger tribute, he appointed Menelaus in place of Jason. In 169, however, while Antiochus was campaigning in Egypt, Jason conquered Jerusalem—with the exception of the citadel—and murdered many adherents of his rival Menelaus. When Antiochus returned from Egypt in 167 he took Jerusalem by storm and enforced its Hellenization. The city forfeited its privileges and was permanently garrisoned by Syrian soldiers.

The revolt of Judas Maccabeus. The Greeks and those friendly toward them were united into the community of Antiochians; the worship of Yahweh and all of the Jewish rites were forbidden on pain of death. In the Temple an altar to Zeus Olympios was erected, and sacrifices were to be made at the feet of an idol in the image of the King. Against that desecration Judas Maccabeus, leader of the anti-Greek Jews, led the aroused Hasideans in a guerrilla war and several times defeated the generals Antiochus had commissioned to deal with the uprising. Judas refused a partial amnesty, conquered Judaea with the exception of the Acra in Jerusalem, and in December 164 was able to tear down the altar of Zeus and reconsecrate the Temple. Antiochus apparently had underestimated the strength of the Hasidean movement, which was behind the success in maintaining an independent Judaean state for about a century. The fighting spirit of the Jews was all the more impressive because at the beginning of their rebellion in 166 Antiochus had just demonstrated his might to the world at Daphne, near Antioch, with a grand review of his army: 46,000 foot soldiers were on parade, among them a Macedonian phalanx of 20,000 men and 500 mercenaries equipped with Roman arms, followed by 8,500 horsemen and 306 armoured elephants.

Antiochus then mounted a campaign against the Parthians who were threatening the empire in the east, recovered the income from that area, forced Artaxias of Armenia—who had defected—to recognize his suzerainty, founded the city of Antioch on the Persian Gulf, set out on an expedition to the Arabian coast, and, at the end of 164, died of an illness at Tabae (or Gabae, probably present Isfahan) in Persis. Many believers saw his death as a punishment for his attempt to loot the shrine of Nanaia in Elam (in modern Iran).

Morkolm, *Antiochus IV of Syria* (1966), a comprehensive biography with extensive literature; E. Bickermann, *Der Gott der Makkabäer* (1937); and S.K. Eddy, *The King Is Dead: Studies in the Near Eastern Resistance to Hellenism 334–31 B.C.* (1961), discuss the response of the Jews toward Antiochus' demand of Hellenization.

• **Antiochus VII SIDETES** (b. c. 159 BC—d. 129), who, after reuniting his country, ruled as king of the Seleucid state of Syria in 139/138–129 BC and successfully recovered much of his forefathers' territory before he was slain by the Parthians.

The son of Demetrius I and brother of Demetrius II, both Seleucid kings, Antiochus spent his youth in the Greek islands. In 141 his brother was captured while fighting the Parthians. Cleopatra Thea, Demetrius II's queen, meanwhile was regent; but a usurper, Tryphon, had risen and threatened to seize full power. At this point, Antiochus VII, an energetic prince, arrived in Syria (139), married Cleopatra Thea, and put Tryphon to flight. A passage in the Bible (I Maccabees 14:1–14) suggests that he first assured himself of the neutrality of possible opponents, such as Judah. By 138, Antiochus had ended Tryphon's career, and he delivered an ultimatum to the Jews to acknowledge him as overlord. When they refused, he sent one army against them,

which was defeated, and, later, in 135/134, himself led a siege, which captured Jerusalem. Internal dissension among the leaders of Judah aided him.

Antiochus razed Jerusalem's walls and made John Hyrcanus, who had recently assumed leadership, his vassal. Rejecting suggestions to exterminate the Jews, he appointed Hyrcanus high priest and allowed religious autonomy.

With Palestine secured, Antiochus set out to restore his forefathers' eastern realm. With enthusiastic support from the Hellenized cities he drove the Parthians from Mesopotamia and invaded Media. The Parthians, perhaps hopeful of stirring up civil war behind him, released Antiochus' brother, who had been a prisoner since 141.

In early 129 the Parthians made a surprise attack on the Seleucid winter quarters and slew Antiochus, who left five children by his queen. Syria lapsed into civil war, with all hopes of empire gone.

The primary source in English of knowledge about the members of the Seleucid dynasty is Edwin Robert Bevan's *The House of Seleucus*, 2 vol. (1902; reprinted 1966).

• **Antiochus HIERAX** (fl. c. 263–226 BC), younger brother of Seleucus II, heir to the Seleucid dominions in the Middle East. During his brother's war with Egypt, he declared independence in Anatolia and attempted to take over the throne.

Antiochus Hierax and Seleucus II, were the sons of Antiochus II's former wife, Laodice. While his brother was involved in the Third Syrian War (246–241) with Egypt, which had erupted over the death of his father's second wife (daughter of Ptolemy II), Antiochus was sent as ruler to Seleucid Anatolia, where Laodice was living. Perhaps in league with his mother, late in the war he sent an army into Syria ostensibly to assist Seleucus but actually to seize the rest of the empire. The appearance of Hierax' troops, however, brought peace between Egypt and his brother, and Seleucus promptly invaded Anatolia and began the War of the Brothers (239–236). Antiochus Hierax fared badly until he allied himself to the Galatians (Celts) and two other states that were traditional foes of the Seleucid kingdom. With the aid of these forces, he inflicted a crushing defeat on his brother's army at Ancyra (236). His alliance with the Galatians, however, provoked the ruler of Pergamum (another Hellenistic state), who, in a war in 236–228, expelled Hierax from Anatolia.

Back in Syria, Antiochus tried to raise revolts against his brother in Syria and the East. Consequently, he was exiled to Thrace in 227, where he lived as a virtual prisoner. The following year he managed to escape and fled to the mountains to raise an army, but he was killed by a band of Galatians.

The primary source in English of knowledge about the members of the Seleucid dynasty is Ernest Robert Bevan's *The House of Seleucus*, 2 vol. (1902; reprinted 1966).

• **Antiochus OF ASCALON** (b. c. 120 BC—d. 68 BC), Greek philosopher who followed Plato of Larissa as the head of the Academy, charting a new course for Platonism. He built up his philosophical system on a foundation of three schools: Platonism, Peripateticism, and Stoicism. Stoic ideas played the most important role in his thinking. He rebelled against two Skeptics, Arcesilaus and Carneades, both of whom had a strong influence on the direction of Platonism, and broke the ground for a more positive direction.

Antiope, in Greek legend, the mother, by the god Zeus, of the twins Amphion and Zethus. According to one account, her beauty

attracted Zeus, who, assuming the form of a satyr, took her by force. Pregnant, she escaped the threats of her father by running away and marrying Epopeus, king of Sicyon; she was later brought back and imprisoned by her uncle Lycus. On the way back from Sicyon, or after escaping from prison, Antiope bore Amphion and Zethus, who were brought up by herdsmen. Later she joined them; they recognized her and killed Lycus and Dirce, his wife. Because of Dirce's murder, Dionysus, to whose worship she had been devoted, caused Antiope to go mad. She wandered restlessly over all of Greece until she was cured and married by Phocus of Tithorea, on Mt. Parnassus.

Antiope was also the name of a daughter of Ares, the god of war, and a queen of the Amazons, a race of warrior women. The Greek hero Theseus stole her for his wife.

Antioquia, department, northwestern Colombia, occupying the northern extreme of the Cordilleras (mountains) Occidental and Central of the Andes. It is bounded northwest by the Caribbean Sea and east by the Río Magdalena. The 24,274 sq mi (62,870 sq km)

Cattle ranch in Antioquia department, Colombia
Carl Frank

area is bisected by the deep gorge of the Río Cauca. The Antioquia highland is diagonally pierced by the canyon of the Río Porce, a Cauca tributary, which widens out into the lovely, mile-high valley where the departmental capital of Medellín is situated.

The colonial economy of Antioquia was based on mining and the department still produces almost all Colombian gold and silver. Antioquia also has large asbestos and copper deposits and is the country's largest coffee producer. Other agricultural products of the region include beans, sugarcane, plantain, rice, bananas, and African palm. Antioquia is supported not only by agriculture and cattle raising, but ranks among the most heavily industrialized regions of Colombia. The department is a major textile area, especially around Medellín, which is also an important transportation centre and the seat of the department's academic and cultural institutions. Pop. (1997 est.) 5,243,906.

antioxidant, any of various chemical compounds added to certain foods, natural and synthetic rubbers, gasolines, and other substances to retard autoxidation, the process by which these substances combine with oxygen in the air at room temperature. Retarding autoxidation delays the appearance of such undesirable qualities as rancidity in foods, loss of elasticity in rubbers, and formation of gums in gasolines. Antioxidants most commonly used are such organic compounds as aromatic amines, phenols, and aminophenols.

Autoxidation has been found to proceed by a chain reaction; that is, a reaction consisting of a series of successive steps occurring in repetitive cycles, in each of which intermediate products called chain carriers are regenerated. Such a reaction will continue as long

as the chain carriers persist. In autoxidation the chain carriers are free radicals, electrically neutral molecular fragments containing unpaired electrons. The chain can be initiated by thermally excited molecules, free radicals, metal catalysts, or light. Antioxidants, by reacting with chain carriers, terminate the oxidative chain reaction.

An example of autoxidation that is of great commercial concern is the one leading to the rancidity of fats, oils, and fatty foods. Rancidity is caused by the degradation of the fat molecule, by reaction with oxygen, to a mixture of volatile aldehydes, ketones, and acids. The reaction can be initiated by exposure to light or by the presence of trace amounts of metals that serve as catalysts. To retard the development of rancidity, organic antioxidants, commonly tocopherol, propyl gallate, butylated hydroxytoluene (BHT), or butylated hydroxyanisole (BHA), are used. These compounds react with chain carriers by donating hydrogen atoms. The use of antioxidants for food is closely regulated in most countries. Specific limitations are normally imposed on the type and quantity of antioxidants that may be used.

antiparticle, subatomic particle having the same mass as one of the particles of ordinary matter but opposite electric charge and magnetic moment. Thus the positron (positive electron) is the antiparticle of the negative electron (negatron). The spinning antineutron with net charge zero, like the ordinary neutron, has its magnetic polarity opposite to that of a similarly spinning neutron. The neutrino, a massless, uncharged particle that travels at the speed of light, spins counterclockwise as viewed from behind, whereas the antineutrino spins clockwise as viewed from behind. A particle and its antiparticle mutually react to produce energy by annihilation.

antipasto, in Italian cuisine, a first course or appetizer (*q.v.*). In the home, cured or smoked meats and sausages, olives, salted anchovies, sardines, fresh or pickled vegetables, shellfish, peppers, and cheeses are favoured, while restaurant presentations add to these elaborate prepared dishes such as seafood salads, stuffed mushrooms, vitello tonnato (cold braised veal in tuna mayonnaise), and the like.

Antipater (b. c. 397 BC—d. 319), Macedonian general, regent of Macedonia (334–23) and of the Macedonian Empire (321–319) whose death signalled the end of centralized authority in the empire. One of the leading men in Macedonia at the death of Philip II in 336, he helped to secure the succession to the Macedonian throne for Philip's son, Alexander the Great, who upon departure for the conquest of Asia (334) appointed Antipater regent in Macedonia with the title of general in Europe. Antipater's main task was to hold the northern frontiers against hostile tribes and to keep order among the Greek states. He ruled Greece by cooperating with the League of Corinth but was unpopular because he supported oligarchic governments. The settlement of the satrapies (provinces) of the Macedonian Empire by the new regent, Perdiccas, at Babylon in 323, immediately after Alexander's death, left Antipater in control of Macedonia and Greece, though as former regent his status in relation to Perdiccas was not clearly defined. Antipater then took the side of the Macedonian generals Antigonos, Seleucus, and Ptolemy, who were opposed to the claims of Perdiccas. By the settlement at Triparadisus, Syria (321), after Perdiccas' death, Antipater became regent of the Macedonian Empire for the two kings: the intellectually retarded Philip III Arrhidaeus and the infant Alexander IV.

Antipater (d. 43 BC), Idumaeen founder of the Herodian dynasty in Palestine. Antipater gained power in Judaea by making himself

useful to the Romans. In return for Antipater's support, Caesar appointed him procurator of Judaea in 47 BC. Although Antipater was assassinated by a political rival four years later, his son, Herod I the Great, was later made king of Judaea by the Romans.

Antipater (d. 4 BC), son of Herod the Great, who conspired against his half brothers Aristobulus and Alexander for the succession to the throne of Judaea and secured their execution (7 or 6 BC). The following year he was tried for plotting against Herod and Pheroras, Herod's brother, and was executed five days before his father's death.

Antiphanes (fl. early 4th century BC, Athens), together with Alexis, the principal representative of the writers of the Middle Comedy at Athens. In this genre, which succeeded the Old Comedy of Aristophanes, scurrility gave place to parody and to criticism of literature and philosophy. Only fragments of Antiphanes' writing survive, though the titles of 134 plays by him are known.

Antiphon (fl. c. 480—411 BC, Athens), orator and statesman, the earliest Athenian known to have taken up rhetoric as a profession. He was a *logographos*; i.e., a writer of speeches for other men to deliver in their defense in court, a function that was particularly useful in the climate of accusation and counter-accusation that prevailed in Athens at the conclusion of the Peloponnesian War, between Athens and Sparta.

As a politician Antiphon was the prime mover in the anti-democratic revolution of the Four Hundred, an oligarchic council set up in 411 BC in an attempt to seize the Athenian government in the midst of war. Others may have been more conspicuous in the forefront of the political struggle, but Thucydides' judgment in his *History*, when describing the revolution of the Four Hundred, is that it was Antiphon "who conceived the whole matter and the means by which it was brought to pass." He was reluctant to put himself forward in public debate because, says Thucydides, he realized that his reputation for cleverness made him unpopular with the people. But when the regime of the Four Hundred fell, he defended himself in a speech Thucydides describes as the greatest ever made by a man on trial for his life. Nevertheless, the defense was unsuccessful and Antiphon was executed for treason.

Fifteen of Antiphon's compositions survive, of which three, "On the murder of Herodes," "On the Choreutes," and "Against a Stepmother," were actually delivered in court. The remaining 12 speeches are arranged in three sets of four known as tetralogies, which were composed as exercises for the instruction of students. Each tetralogy consists of two speeches each for the defense and the prosecution in a homicide case.

The 1st-century-BC teacher of rhetoric Dionysius of Halicarnassus selected Antiphon's work as an example of the austere in oratory. His language is dignified and he nowhere indulges in the personal abuse that characterizes many of the later orators. Even when he is dealing with actual events, however, he seems remote from the realities of the situation, and he makes no attempt to suit his speeches to the differing personalities of those who were to deliver them. An edition by K.J. Maidment in *Minor Attic Orators*, volume 1, is in the Loeb Classical Library with Greek text and English translation.

antiphon, in Roman Catholic liturgical music, chant melody and text sung before and

after a psalm verse, originally by alternating choirs (antiphonal singing). Antiphonal psalm singing was adopted from Hebrew worship by the early Christian churches, notably that of Syria, and was introduced into the West in the 4th century by St. Ambrose. The two choirs both sang the psalm text or, alternatively, one choir sang a short refrain between the psalm verses (V) sung by the other choir. The refrain was called an antiphon (A). The resulting musical form was A V₁ A V₂ . . . A. Actually, most of the presentations of the antiphon were in abbreviated form. The antiphon text normally referred to the meaning of the feast day or the psalm. Canticles from the New or Old Testament might also be sung in this way.

Antiphons are now found principally in the canonical hours, or divine office. The parts of the mass known as the introit, offertory, and communion originally consisted of antiphons and psalm verses. During the late Middle Ages the psalm verses were dropped from the offertory and communion, which now consist only of an antiphon. The introit was shortened to one psalm verse and an antiphon (A V A). Musically, the several thousand extant antiphons can be reduced to a small number of melodic types of simple structure. The old antiphonal method of performance was eventually abandoned, and antiphonal chants are now frequently sung responsorially, *i.e.*, by soloist (or soloists) and choir.

The four Marian antiphons are long hymns, not true antiphons but independent compositions especially noted for their beauty: the "Salve Regina" ("Hail, Holy Queen"), "Ave Regina caelorum" ("Hail, Queen of Heaven"), "Regina caeli, laetare" ("Queen of Heaven, Rejoice"), and "Alma Redemptoris Mater" ("Kindly Mother of the Redeemer"). They were frequently set polyphonically (in part music) by composers from about 1400 onward. There are also special "antiphons" used for processions at certain high feasts.

Antipodes Islands, outlying island group of New Zealand in the South Pacific Ocean, 350 miles (560 km) southeast of South Island, comprising a central island (5 by 3 miles [8 by 5 km]) and several islets. The total land area is 24 square miles (62 sq km). Coastal cliffs flank an interior that rises to 1,320 feet (402 m) at Mount Galloway. Discovered in 1800 by the crew of the British ship *Reliance*, the Antipodes were once the home of large herds of fur seals, which have been drastically reduced by uncontrolled hunting. The islands are uninhabited.

Antipolo, municipality, central Luzon, Philippines. Lying 12 miles (19 km) east of Manila in the Sierra Madre foothills, it was founded in 1578. Antipolo is the home of the icon of Nuestra Señora de la Paz y Buen Viaje ("Our Lady of Peace and Safe Voyage"). The icon, after repeated safe journeys between New Spain (Mexico) and the Philippines early in the 17th century, became known as the heavenly protector of Spain's galleons. After Franciscan priests first enshrined it, Jesuits moved the icon to its present location, a hillside shrine near Antipolo, in 1632. It is the focus of pilgrimages each May.

Government-sponsored housing has been built near Antipolo. A highway to Quezon City was completed in the 1980s. Pop. (1995 est.) city, 120,000; (2000 prelim.) mun., 460,000.

antipope, in the Roman Catholic church, one who opposes the legitimately elected bishop of Rome, endeavours to secure the papal throne, and to some degree succeeds materially in the attempt. This abstract definition is necessarily broad and does not reckon with the complexity of individual cases. The elections of several antipopes are greatly obscured by incomplete or biased records, and at times even their contemporaries could not decide who was the true pope. It is impossible, therefore, to estab-

lish an absolutely definitive list of antipopes. Historically, antipopes have arisen as a result of a variety of causes; the following are some examples:

1. Doctrinal disagreement. The spread of Monarchianism (a Trinitarian heresy) led a Roman priest, Hippolytus, to try to replace Pope Calixtus I in the 3rd century. Hippolytus was later reconciled to Pope Pontianus during the persecution of Maximinus and died a martyr's death (235).

2. Deportation of the pope. The Arian emperor Constantius II exiled Pope Liberius for his orthodoxy (355) and imposed the archdeacon Felix on the Roman clergy as Pope Felix II. Eventually, Liberius was allowed to return, and Felix lived in retirement until his death.

3. Double elections arbitrated by the secular authority. In 418 the archdeacon Eulalius was elected by a faction partial to him, and he was supported by the imperial prefect and the Byzantine court. The rest of the clergy, however, chose the priest Boniface I, who was eventually given official recognition by the emperor.

4. Double elections and subsequent recourse to a third candidate. In the 7th century Paschal and Theodore were rivals for the papacy, and both were unwilling to renounce their claims. Finally, a part of the community more in-

Tentative List of Antipopes

Hippolytus (217, 218–235)	Anastasius (855)	Anacletus (II) (1130–38)
Novatian (251)	Christopher (903–904)	Victor (IV) (1138)
Felix (II) (355–358)	Boniface VII (974, 984–985)	Victor (IV) (1159–64)
Ursinus (366–367)	John XVI (or XVII) (997–998)	Paschal (III) (1164–68)
Eulalius (418–419)	Gregory (VI) (1012)	Calixtus (III) (1168–78)
Laurentius (498, 501–c. 505/507)	Benedict X (1058–59)	Innocent (III) (1179–80)
Dioscorus (530)	Honorius (II) (1061–72)	Nicholas (V) (1328–30)
Theodore (687)	Clement (III) (1080–1100)	Clement (VII) (1378–94)
Paschal (687)	Theodoric (1100–02)	Benedict (XIII) (1394–1423)
Constantine (II) (767–768)	Albert (or Aleric) (1102)	Alexander (V) (1409–10)
Philip (768)	Sylvester (IV) (1105–11)	John (XXIII) (1410–15)
John (844)	Gregory (VIII) (1118–21)	Clement (VIII) (1423–29)
	Celestine (II) (1124)	Felix (V) (1439–49)

clined to moderation gained the papacy for Sergius I.

Somewhat similarly, in the 14th century the official residence of the papacy was moved to Avignon, Fr. This led to a schism (the Great Western Schism) beginning in 1378 that resulted in a papacy in Rome (regarded as canonical), a papacy in Avignon (regarded as antipapal), and eventually a third papacy established by the Council of Pisa (also regarded as antipapal). Unity was finally achieved by the election of Martin V on Nov. 11, 1417.

5. Change in the manner of choosing the pope. In 1059 a new procedure for electing popes, proclaimed by Pope Nicholas II, deprived the German emperors of the leading role that they had played in earlier papal elections and also limited the influence of the Roman nobility. This led to the election of the antipope Honorius II in opposition to the canonically elected Alexander II, who was eventually recognized by the emperor. *See also* papacy (table).

antiproton, subatomic particle of the same mass as a proton but having a negative electric charge and oppositely directed magnetic moment. It is the proton's antiparticle. Antiprotons were first produced and identified in 1955 by Emilio Segrè, Owen Chamberlain (for which they received the Nobel Prize for Physics in 1959), and coworkers by bombarding a copper target with high-energy protons from the proton synchrotron at the University of California at Berkeley. Antiprotons were predicted in the early 1930s, but their discovery had to wait for the technology of high-energy particle accelerators to reach the 6 billion electron-volt range. A collision of an antiproton with a proton results in mutual annihilation, but a near miss may produce by charge exchange an antineutron-neutron pair.

antipyrine, analgesic now little used, though it is the oldest of the synthetic drugs that relieve pain and reduce fever. It also has a mild anesthetic effect. Antipyrine was introduced in 1887.

Antipyrine is longer acting than aspirin (a single dose can give relief from pain for 24 hours), and in most people it has very few side effects. But a small minority of persons are highly allergic to antipyrine, and in them the drug can cause severe skin eruptions, giddiness, tremor, vascular collapse, and even coma and death. In combination with benzocaine, antipyrine is still sometimes used as a topical agent to relieve earache. The use of antipyrine has been greatly reduced since its undesirable side effects have been recognized.

antique, a relic or old object having aesthetic, historic, and financial value. Formerly, it referred only to the remains of the classical cultures of Greece and Rome; gradually, decorative arts—courtly, bourgeois, and peasant—of all past eras and places came to be considered antique.

Antiques have been variously defined by law for tariff purposes. The U.S. Tariff Act of

1930 exempted from duty specified antiquities and objects of art produced prior to 1830, and that year became more or less internationally accepted as an appropriate terminal date in defining "antique." In 1952 the Florence Agreement, sponsored by UNESCO and signed by 17 countries, agreed to "facilitate the free flow of educational, scientific and cultural materials by the removal of barriers that impede the international movement of such materials," and antiques were affected by subsequent legislation adopted in the participating countries to implement the agreement. The United States, for instance, passed a new tariff act in 1966 permitting the duty-free importation of "antiques made prior to 100 years before their date of entry"; comparable regulations had already gone into effect in other participating countries. In general usage, antiques frequently are now defined as objects of artistic and historical significance that are at least 100 years old.

The collecting of antiques goes back almost as far as history, beginning with the preservation of temple treasures. In England, concern for the historical as well as aesthetic significance of antiques led, as early as the 16th century, to collections illustrating the national past. In 1857 the museum now called the Victoria and Albert opened in London as a repository for decorative arts, intended to stimulate designers as well as collectors. It was followed in 1863 by a great public collection in Vienna, in 1882 by the Museum of Decorative Arts in Paris, and in 1897 by the Museum of the Arts of Decoration at Cooper Union School of Art and Architecture in New York City. Collecting antiques became a truly popular pursuit in the 20th century.

Antiquities of the Jews, The, Latin ANTIQUITATES JUDAICAE, an account of Jewish

history from its early beginnings to the revolt against Rome in AD 66, written in Greek in about AD 93 by Flavius Josephus, a general in the Jewish army who defected to Rome. His writings are not always accepted as totally reliable.

Antirent War (1839–46), in U.S. history, civil unrest and rioting in upper New York state arising from the dissatisfaction of leaseholding farmers over the patroon system then prevailing on the great hereditary estates, originally established by the Dutch. In addition to rent, a farmer had to provide certain services to the landowner; the farmer's position was similar to that of a copyholder or villein under European feudalism. On the sale of the lease, a New York farmer had to pay the proprietor an alienation fine of from one-tenth to one-third of the sale price.

While this system had long been considered unjust, no direct action was taken until 1839, when the heirs of Stephen Van Rensselaer tried to collect back rent from leaseholders in Albany County. The farmers rose in active opposition and refused to pay. Violence broke out and Gov. William H. Seward called out the militia. But acts of resistance spread, especially against rent and tax collectors, and Gov. Silas Wright declared martial law in August 1845. Thereafter, the disturbances lessened, and they finally ceased when a new state constitution in 1846 abolished the leasehold system of land tenure and instituted fee-simple ownership.

antiseptic, any of several substances used to inhibit the growth of or destroy infectious microorganisms. *See* antimicrobial agent.

antiserum, blood serum that contains specific antibodies against an infective organism or poisonous substance. Antiserums are produced in animals (*e.g.*, horse, sheep, ox, rabbit) and man in response to infection, intoxication, or vaccination and may be used in another individual to confer immunity to a specific disease or to treat bites or stings of venomous animals. Antiserums from animals are most often used, but in persons allergic to animals, human antiserums have proved valuable. *See also* antibody; antitoxin; immunization; vaccine.

Antisthenes (b. c. 445 BC—d. c. 365), Greek philosopher, of Athens, who was a disciple of Socrates and is considered the founder of the Cynic school of philosophy, though Diogenes of Sinope often is given that credit.

Antisthenes was born into a wealthy family, and the philosophical ideas that he developed had their roots in the contradictions and injustices that he found embedded in society. He sought to build a foundation of ideas that

Antisthenes, herm; in the Sala delle Muse, Vatican

By courtesy of the Direzione Generale dei Monumenti, Musei e Gallerie Pontificie

would serve as a guiding principle toward a happier, more thoughtful way of life. Antisthenes believed that happiness was dependent on moral virtue and that virtue could be instilled through teaching.

In teaching people how to be virtuous, Antisthenes demarcated two categories of objects: (1) external goods, embracing such elements as personal property, sensual pleasure, and other luxuries; and (2) internal goods, including the truth and knowledge of the soul. He advocated great restraint on the part of an individual tempted to take pleasure in external goods, and he encouraged his students to accept the burden of physical and mental pain that accompanies the soul's search for its own inner wealth. To dramatize his method of teaching, Antisthenes, after the myth of Hercules, would stand on his platform of ideas and beliefs and "bark" at the folly and injustices of his society. The Cynic (Greek: Canine, or Doglike) school of philosophy long survived him.

antitank weapon, any of several guns, missiles, and mines intended for use against tanks. The first response to the introduction of tanks during World War I was a variety of projectiles designed to penetrate their relatively thin armour. Land mines and ordinary artillery were also used effectively. By the beginning of World War II a family of antitank guns, mostly of 37-millimetre (1.46-inch) calibre, had emerged, firing special ammunition. During the war increasingly larger calibres were used, and a variety of ammunition types—including shells tipped with harder alloys, improved propellants to give higher velocities, and more powerful explosives—were developed. Especially effective was the shaped or hollow charge shell, designed to explode on impact and channel the explosive energy forward, enhancing penetrating force.

World War II also produced a variety of antitank missiles and launching devices, of which the American bazooka (*q.v.*) and its counterparts in other armies were the best known; these were small, short-range rocket launchers carried and aimed by a single operator. After World War II the technology of antitank weaponry advanced in several directions. Most important was a new family of electronically guided missiles, employing either beam- or wire-guidance systems. By the early 1970s these had attained a high degree of refinement in accuracy, range, and versatility, as was dramatically demonstrated in the Yom Kippur War of October 1973, in which the effectiveness of the Soviet-supplied Arab weapons against Israeli tanks seemed to portend a new era of defensive supremacy in land warfare. Antitank guns also developed rapidly in this period, with further improvements in propellants, explosives, projectiles, and the design of gun tubes. Some antitank guns were smooth-bored instead of rifled in order to fire both missiles and projectiles.

antithesis (from Greek *antitheton*, "opposition"), a figure of speech in which irreconcilable opposites or strongly contrasting ideas are placed in sharp juxtaposition and sustained tension, as in the saying "Art is long, and Time is fleeting."

The opposing clauses, phrases, or sentences are roughly equal in length and balanced in contiguous grammatical structures.

The world will little note nor long remember what we say here, but it can never forget what they did here.

(Abraham Lincoln, "Gettysburg Address")

In poetry, the effect of antithesis is often one of tragic irony or reversal.

Saddled and bridled
And booted rade he;
A plume in his helmet,
A sword at his knee;
But toom [empty] cam' his saddle
A' bloody to see,
O hame cam' his gude horse
But never cam' he!
("Bonnie George Campbell," anonymous)

antitoxin, antibody, formed in the body by the introduction of a bacterial poison, or toxin,

and capable of neutralizing the toxin. People who have recovered from bacterial illnesses often develop specific antitoxins that confer immunity against recurrence.

For medical use in treating human infectious diseases, antitoxins are produced by injecting an animal with toxin; the animal, most commonly a horse, is given repeated small doses of toxin until a high concentration of the antitoxin builds up in the blood. The resulting highly concentrated preparation of antitoxins is called an antiserum.

The first antitoxin, to diphtheria, was discovered in 1890 by Emil von Behring and Shibasaburo Kitasato, for which Behring received the 1901 Nobel Prize for Physiology or Medicine. Today, antitoxins are used in the treatment of botulism, diphtheria, dysentery, gas gangrene, and tetanus. If the toxin is a venom, the antitoxin formed, or the antiserum containing it, is called an antivenin. *See also* antiserum.

antitrade wind, steady wind that blows poleward and eastward between latitudes 30° N and 30° S, at altitudes of 2 to 12 kilometres (about 1 to 7 miles). Such winds overlie the westward-blowing trade winds and descend poleward, where they merge with the mid-latitude westerly winds. The subtropical high-pressure belts at 30°–35° N and 30°–35° S result partially from the descent of the antitrades to the surface. *See also* atmospheric circulation.

antitrust law, any law restricting business practices considered unfair or monopolistic. The United States has the longest standing policy of maintaining competition among business enterprises through a variety of laws. The best known is the Sherman Antitrust Act of 1890, which declared illegal "every contract, combination . . . or conspiracy in restraint of trade or commerce." Another important U.S. antitrust law, the Clayton Antitrust Act of 1914, as amended in 1936 by the Robinson-Patman Act, prohibits discrimination among customers through prices or other means; it also prohibits mergers of firms, or acquisitions of one firm by another, whenever the effect may be "to substantially lessen competition."

In Europe, antitrust legislation received much attention after World War II, when provisions against restraint of competition were embodied in a number of national laws and international agreements. The Commission of the European Communities in Brussels regularly passes upon cases involving practices of companies trading in the Common Market; its decisions are based upon Articles 85 and 86 of the Treaty of Rome (1957), which deal with rules of fair competition.

Antium (Italy): *see* Anzio.

Antler orogeny, a mountain-building event in Late Devonian and Mississippian time (about 340,000,000 to 350,000,000 years ago) that affected a linear belt in the Cordilleran Geosyncline, extending from the California-Nevada border northward through the central part of Nevada into Idaho. The term Antler Orogenic Belt, and formerly Manhattan Geanticline, is applied to the deformed rocks produced by this orogeny.

Evidence for the Antler orogeny consists of the widespread extent of coarse clastic sediments of Mississippian and Early Pennsylvanian age east and west of the belt and the development of a very prominent eastward-moving thrust fault in Early Mississippian time, the Roberts Mountain Thrust.

antlerite, a copper sulfate mineral, $\text{Cu}_3(\text{SO}_4)(\text{OH})_4$, that is found in the oxidized zone of copper deposits, particularly in arid regions. At Bisbee, Ariz; Kennicott, Alaska; Sierra Mojada, Coahuila, Mex.; and Chuquicamata, Chile, it is the principal copper ore mineral.

Antlerite from Puerto de Gomez, Chihuahua, Mex.

For detailed physical properties, see sulfate mineral (table).

antlike flower beetle, any of the approximately 1,000 species of the insect family Anthicidae (order Coleoptera). They are usually seen around flowers, foliage, refuse, or dead wood.

These voracious beetles resemble ants and range from 2 to 12 millimetres (up to 1/2 inch) in length. Some can be found in debris and under stones and logs.

antlion, any insect larva of the neuropteran family Myrmeleontidae. The oval, sandy-gray abdomen of the larva is covered with bristles; the prothorax forms a mobile neck; and the large square head has powerful, sickle-like jaws. The antlion digs a funnel-shaped pit (from 2.5 to 5 centimetres deep and 2.5 to 7.5 centimetres wide at the edge) by using its abdomen as a plow, heaping the loosened particles on its head and throwing them clear of the pit. When the pit is completed the larva buries itself so that only its jaws project. Any small insect that ventures over the edge of the sandy pit slips to the bottom and is seized by the antlion. After sucking the contents of its victim, the antlion throws the empty skin out of the pit. The larvae of certain species (e.g., the spotted-winged antlion, *Dendroleon obsoletus*) do not make a pitfall but seize passing prey from a hiding place.

After a period of feeding and growth the larva prepares a cocoon of sand and spun silk; it emerges as a sexually mature adult. The adult antlion, a weak flier, has relatively short, clubbed antennae and four narrow, delicate, densely net-veined wings that may be marked with brown or black. Since the adult does not feed, the larva must consume sufficient food to sustain the adult.

Antlion

William E. Ferguson

Myrmeleon formicarius, the best known of the 65 described species, occurs in both North America and Europe but not in England; it matures in late summer. In the United States the antlion is frequently known as a doodlebug.

Antofagasta, region, in an extremely arid part of northern Chile, bounded on the east by Bolivia and Argentina and on the west by the Pacific Ocean. Antofagasta (area 48,642 sq mi [125,981 sq km]) is the second largest of Chile's regions; about 90 percent of its population lives in urban areas, chiefly

the capital city of Antofagasta (q.v.), and in Tocopilla, Calama, and Chuquicamata. Occupied in 1879 by Chilean forces early in the War of the Pacific, it was ceded by Bolivia in 1884 and created a Chilean province in 1888 and a region in 1974. It includes the provinces of Tocopilla, Antofagasta, and El Loa. The population grew greatly after the discovery of nitrate deposits in 1866, mainly in the Pampa del Tamarugal, lying between the coastal range and the volcanic Andes. After World War I, nitrate prices fell, and the population declined. From the region now, comes more than 50 percent of Chile's copper production, especially from Chuquicamata. Borax, sulfur, and iodine are also important mineral resources. It is the leading region in road and railroad mileage and is linked with the rest of Chile and with Oruro, Bolivia, and Salta, Arg. Pop. (1982 prelim.) 341,203.

Antofagasta, capital of Antofagasta province and Antofagasta region, northern Chile, and a Pacific port on Bahía (bay) Moreno. A Bolivian city before 1879, it occupies a terrace at the base of bleak, arid coastal mountains. Its early growth resulted from the nitrate boom that began in 1866 and from the Caracoles

The cathedral on Plaza San Martín, Antofagasta, Chile

silver discovery of 1870, at which time Antofagasta's name became official. Supplying the mines and exporting copper and sulfur continue as its major functions. Besides foundries and refineries, ore-concentration and sulfuric acid manufacturing facilities, there are local food and beverage processing and fish-meal production industries. There is also a shipyard for trawlers. The largest city in northern Chile, Antofagasta is the site of the University of the North (founded in 1956). It is also a communications centre on the Pan-American Highway, is linked by rail to the mines, to Oruro, Bolivia, and to Salta, Arg., as well as to urban areas to the north and south, and has an international airport. Pop. (1982 prelim.) 183,365.

Antoine (French personal name): see under Anthony.

Antoine, André (b. Jan. 31, 1858, Limoges, Fr.—d. Oct. 19, 1943, Pouliguen), actor, theatrical manager, critic, and film director, a pioneer of naturalistic drama who founded the Théâtre-Libre in Paris. His contributions to the development of realism in modern films was only beginning to gain appreciation in the second half of the 20th century.

Largely self-educated, Antoine was working as a clerk for the Paris Gas Company and acting part-time when in 1887 he founded the Théâtre-Libre as a showcase for the work of contemporary naturalistic playwrights. Despite an initially unenthusiastic reception he soon won wide acceptance and began financing his productions through private subscription.

In its heyday (1887–93), the Théâtre-Libre

introduced to French audiences the work of Brieux, Ibsen, Hauptmann, Strindberg, and others. It greatly influenced the modern French theatre and spawned a host of imitators around the world, among them the Freie Bühne in Berlin and the Independent Theatre in London. In 1896 financial losses forced him to close the theatre, but a year later, after serving briefly as co-director of the Théâtre de l'Odéon, he founded the Théâtre-Antoine, offering productions similar to those of his original company. In 1906 he was appointed sole director of the Odéon; he resigned after eight years to become a drama critic and an extremely innovative film director (1914–24). He directed such films as *Les Frères corses* (1915), *Mademoiselle de la Seiglière* (1920), and *L'Arlésienne* (1921).

Antoku, in full AN TOKU TENNŌ, personal name TOKIHI TO (b. Dec. 22, 1178, Kyōto—d. April 25, 1185, Nagato Dannoura, Japan), 81st emperor of Japan; his death in the famous naval Battle of Dannoura (1185) on the Inland Sea in western Japan resulted in the loss of the great sword that was one of the Three Imperial Regalia, the symbols of Imperial authority, supposedly brought to earth when the first Japanese emperor descended from heaven.

He was placed on the throne in 1180, at the age of two, by the Taira clan, and assumed the reign name Antoku. Because of his youth, real power resided in the hands of the former emperor Shirakawa and Antoku's grandfather, the renowned warrior Taira Kiyomori. In 1181 the Taira clan was driven from Kyōto, the capital city, by forces under the control of Minamoto Yoshinaka. The Tairas fled westward, taking Antoku with them. The Minamotos pursued the Tairas, finally annihilating them four years later at the Battle of Dannoura, during which, in an attempt to escape capture, Antoku and his attendants jumped into the sea and drowned.

Anton (Czech, Danish, Dutch, Romanian, etc., personal name): see under Anthony.

Antonelli, Giacomo (b. April 2, 1806, Sonnino, Papal States—d. Nov. 6, 1876, Vatican City), cardinal and secretary of state to Pope Pius IX.

Though he was never ordained as a priest, Antonelli was created cardinal by Pius in 1847 and became premier (1848) of the Papal States, which were then governed for the first time by a democratic constitution. After his own and succeeding governments had fallen and the revolutionary situation at Rome had led to the assassination of the papal premier Count Pellegrino Rossi in 1848, he courageously remained with Pius at the Quirinal and planned the Pope's flight to Gaeta, Italy, where Antonelli was made acting secretary of state.

After the Pope's return to Rome in 1850, Antonelli was officially appointed secretary of state, which he remained until his death. He was in general control of the government of the Papal States until their elimination in 1870 and was in charge of the Pope's relations with other governments until 1876. His policy was to avoid further attempts to introduce constitutional government into the Papal States because he felt it was impossible either to distinguish the pope's spiritual from his temporal power or to subject him to a lay assembly. As a diplomatic opportunist, Antonelli knew that his only hope of preserving the Pope's temporal sovereignty over central Italy during the growing movement for Italian unity was to retain the goodwill of the French government of Napoleon III, which had maintained a garrison in Rome after 1850. He was therefore opposed to the raising of a papal army, which

took place in 1860, and to all quarrels with Paris. When the Piedmontese forces entered Rome (1870), he requested them to preserve order by extending occupation around the Vatican, and the papal army was disbanded. Despite his faithful service to the Pope, Antonelli died little mourned by him because of frequent reports of the impurity of his life and of the wealth he accumulated while in office.

Antonello DA MESSINA (b. c. 1430, Messina, Sicily—d. c. Feb. 19, 1479, Messina), painter who probably introduced oil painting and Flemish pictorial techniques into mid-15th-century Venetian art. His practice of building form with colour rather than line and

"Portrait of a Man," panel painting by Antonello da Messina, c. 1472; in the National Gallery, London
By courtesy of the trustees of the National Gallery, London

shade greatly influenced the subsequent development of Venetian painting.

Little is known of Antonello's early life, but it is clear that he was trained in Naples, then a cosmopolitan art centre, where he studied the work of Provençal and Flemish artists, especially that of Jan van Eyck. His earliest known works, a "Crucifixion" (c. 1455; Museum of Art, Sibiu, Rom.) and "St. Jerome in His Study" (c. 1460; National Gallery, London), already show Antonello's characteristic combination of Flemish technique and realism with typically Italian modelling of forms and clarity of spatial arrangement.

In 1457 Antonello returned to Messina, where he worked until 1474. The chief works of this period, the polyptych of 1473 and the "Annunciation" of 1474 (both in the Museo Nazionale, Messina), are relatively conservative altarpieces commissioned by the church, but the "Salvator Mundi" (1465; National Gallery, London), intended for private devotions, is bold and simple, showing a thorough understanding of the human form and the depiction of personality. It was but a short step from the "Salvator Mundi" to such incisive characterizations of human psychology as seen in "Portrait of a Man" (c. 1472; National Gallery, London), a work that presaged the uncanny vitality and meticulous realism of such panels as "Portrait of a Condottiere" (1475; Louvre, Paris), which established his reputation in northern Italy.

From 1475 to 1476 Antonello was in Venice and possibly Milan. Within a short time of his arrival in Venice, his work attracted so much favourable attention that he was supported by

the Venetian state, and local painters enthusiastically adopted his oil technique and compositional style. In "St. Sebastian" (c. 1476; Gemäldegalerie, Dresden, Ger.), his most mature work, Antonello achieved a synthesis of clearly defined space, monumental, sculpture-like form, and luminous colour, which was one of the most decisive influences on the evolution of Venetian painting down to Giorgione's day. In 1476 he was again in Messina, where he completed his final masterpiece, "The Virgin Annunciate" (c. 1476; Galleria Nazionale, Palermo).

Antonescu, Ion (b. June 15, 1882, Pitești, Rom.—d. June 1, 1946, near Jilava), Romanian general and statesman who became dictator of the pro-German government during World War II.

After World War I, Antonescu served as military attaché in Paris and in London and, in 1934, as chief of the Romanian general staff. Named minister of defense in 1937, he retained office with the establishment of King Carol II's corporatist dictatorship (1938), only to be dismissed after a few weeks as a sympathizer of the principal Romanian Fascist group, the Iron Guard.

Appointed prime minister Sept. 4, 1940, after Romania had lost one third of its territory partitioned among the Axis powers and the U.S.S.R. (June–September 1940), Antonescu established a Fascist dictatorship and openly embraced the Axis powers. His "National Legionary State" briefly brought the Iron Guard to power; but, after a period of Guardist revolutionary and criminal excesses, he suppressed the organization (1941). He at first secured widespread popular support for his domestic reform program and, as Germany's ally, for his declaration of war against the U.S.S.R. (1941). His administration also permitted a certain latitude to opposition critics, and some historians believe it may have been the least servile among the German satellite governments. His popular support gradually eroded, however, as manpower losses mounted on the Russian front. His regime was finally toppled by a coup d'état in August 1944 led by King Michael; Antonescu subsequently was sentenced to death by the Romanian Communist people's court and was executed as a war criminal.

Antonin (French chef): *see* Carême, Marie-Antoine.

Antonina, port, eastern Paraná state, southeastern Brazil, at the head of the Baía (bay) de Paranaguá, an inlet of the Atlantic Ocean, northwest of the port of Paranaguá and east of Curitiba, the state capital. Wood and maté (tea), from Ponta Grossa, 100 mi (160 km) inland, and bananas and iron ore are exported. There is some iron smelting, based on nearby magnetite deposits. Other industries include rice processing, wood veneer production, sugar and flour milling, and the manufacture of rope. Pop. (2000 prelim.) city, 15,814; mun., 19,146.

Antonine, either of the Roman emperors Antoninus Pius (reigned AD 138–161) and his adopted heir Marcus Aurelius (161–180). The term Antonines also usually includes Lucius Verus (161–169), another adopted heir of Antoninus Pius and co-emperor with Marcus Aurelius, as well as Commodus (176–192), son of Marcus Aurelius and co-emperor and then sole emperor. The Antonine period 138–180 was one of great internal peace and prosperity, when the sense of unity, the reconciliation of peoples, was greatest throughout the Roman Empire. *See* Five Good Emperors.

Antonine Wall, Roman frontier barrier in Britain, extending about 36½ miles (58.5 kilometres) across Scotland between the Clyde River and the Firth of Forth. Ordered by the Roman emperor Antoninus Pius, the wall was built in AD 142 by Lollius Urbicus, governor

of Britain. The wall was 14 to 16 feet (4½ metres) wide and probably 10 feet (3 metres) high; a ditch 40 feet (12 metres) wide and 12 feet (4 metres) deep ran in front of the wall, and a military road ran behind it. A series of 19 forts, separated by intervals of 2 miles (3 kilometres), controlled the wall.

Construction of the wall extended the northern boundary of Roman Britain farther into Scotland and provided defense beyond Hadrian's Wall, which had been completed some 100 miles (160 kilometres) to the south in about 136. Occupation of the Antonine Wall was interrupted during the northern revolt (AD 155–158), and the garrison withdrew to Hadrian's Wall not later than the year 196. Traces of the wall still remain.

Antoninus, SAINT, original name ANTONINO PIEROZZI, or DE' FORCIGLIONI, Antonino also spelled ANTONIO (b. March 1, 1389, Florence—d. May 2, 1459, Florence; canonized 1523; feast day May 10), archbishop of Florence who is regarded as one of the founders of modern moral theology and Christian social ethics.

In Florence Antoninus joined the Dominican order (1405); he became an active leader of the order's Observant movement, especially at Fiesole, near Florence. As vicar of the Observants he founded the convent of San Marco, Florence, in 1436. There he served as prior (1439–44) and attended the Council of Florence (1439–45).

He became archbishop of Florence (1446), where he was greatly beloved for his charity and particularly for his indefatigable aid during the plague of 1448 and the earthquake 1453. He was canonized by Pope Adrian VI. Antoninus' principal works are his *Summa moralis* (Venice, 1477) and *Summa confessionum* (Mondovi, 1472).

Antoninus Pius, in full CAESAR TITUS AELIUS HADRIANUS ANTONINUS AUGUSTUS PIUS, original name TITUS AURELIUS FULVIUS BOINIUS ARRIUS ANTONINUS (b. Sept. 19, 86, Lanuvium, Latium—d. March 7, 161, Lorium, Etruria), Roman emperor from AD 138

Antoninus Pius, marble bust; in the British Museum

to 161. Mild-mannered and capable, he was the fourth of the "five good emperors" who guided the empire through an 84-year period (96–180) of internal peace and prosperity. His family originated in Gaul, and his father and grandfathers had all been consuls.

After serving as consul in 120, Antoninus was assigned by the emperor Hadrian (ruled 117–138) to assist with judicial administration in Italy. He governed the province of Asia (c. 134) and then became an adviser to the Emperor.

In 138 Antoninus was adopted by Hadrian and designated as his successor. Hadrian specified that two men—the future emperors Marcus Aurelius and Lucius Verus—were to succeed Antoninus. Upon acceding to power, Antoninus persuaded a reluctant Senate to offer the customary divine honours to Hadrian. For this, and possibly other such dutiful acts, he was given the surname Pius by the Senate. When his wife, Faustina, died in late 140 or early 141 he founded in her memory the *Puellae Faustinae*, a charitable institution for the daughters of the poor.

References to Antoninus in 2nd-century literature are exceptionally scanty; it is certain that few striking events occurred during his 23-year reign. A rebellion in Roman Britain was suppressed, and in 142 a 36-mile (58-kilometre) garrisoned barrier—called the Antonine Wall—was built to extend the Roman frontier some 100 miles north of Hadrian's Wall (*q.v.*). Antoninus' armies contained revolts in Mauretania, Germany, Dacia, and Egypt.

The feeling of well-being that pervaded the empire under Antoninus is reflected in the celebrated panegyric by the orator Aelius Aristides in 143–144. After Antoninus' death, however, the empire suffered invasion by hostile tribes, followed by severe civil strife.

Antonio (Italian, Spanish, etc., personal name): *see under* Anthony, except as below.

António, PRIOR OF CRATO, Portuguese PRIOR DO CRATO, byname DOM ANTÓNIO (b. 1531, Lisbon—d. Aug. 26, 1595, Paris), ecclesiastic and claimant to the throne of Portugal who never gained the crown despite armed assistance from France and England.

António was the illegitimate son of Luís, duke of Beja, brother of King John III of Portugal. He became head of the Order of St. John in Portugal and was endowed (1555) with the wealthy priory of Crato. He accompanied King Sebastian (reigned 1557–78), John III's grandson, to North Africa, where, in the Battle of the Three Kings (1578), Sebastian was killed and António captured. On his return to Portugal, António's claim to the throne was rejected by Sebastian's successor Henry, the last surviving brother of John III, and later by the council that governed Portugal for some months after Henry's death (January 1580). In June 1580 he was acclaimed king as António I at Santarém by his supporters. His possession of the crown, however, was contested by Philip II of Spain, whose army, under the Duke of Alba, defeated António outside Lisbon two months later. The Spanish king then became Philip I of Portugal, and António sought refuge in Paris.

With French help, António sent two naval expeditions (1582 and 1583) to the Azores, where he was still recognized as king. Both of his forces were defeated by Spanish squadrons. He next went to England, where he enlisted the assistance of Elizabeth I. An English fleet under Sir Francis Drake and Sir John Norris effected a landing near Lisbon in support of António in 1589, but the expedition proved a costly failure. Impoverished and in ill health, António returned to Paris, where he planned further expeditions until his death.

António, Mário, original name MÁRIO ANTÓNIO FERNANDES DE OLIVEIRO (b. April 5, 1934, Maquela do Zombo, Angola), scholar, short-story writer, and poet whose works focus alternately on Angolan and Portuguese cultures. A poet of personal love and social protest in his early years, António in his later poems frequently presents verbal portraits of moods, places, and experiences.

He completed his primary and secondary studies in Luanda. After spending 11 years as a public civil servant in the Angolan capital, he moved to Lisbon in 1963. He visited and lectured in the United States in 1979.

António argued in his essays that Portuguese colonialism produced a creole, or mixed, culture in Angola in which European and African attitudes, values, and perspectives were shared by whites and blacks, as well as mulattos. He is a prolific contributor to journals and magazines in Angola and Portugal. His principal volumes of poetry include *Amor: poesias* (1960; "Love: Poems"), *100 Poemas* (1963), and *Rosto de Europa* (1968; "Face of Europe"). By the mid-1980s he was the author of more than 20 works in Portuguese, including the poems, several collections of stories, cultural and literary essays on 19th- and 20th-century Angola, and translations.

Antonio, Nicolás (b. July 28/31, 1617, Seville—d. April 13, 1684, Madrid), first systematic historian of Spanish literature. His *Bibliotheca Hispana* appeared in two parts (*Nova*, 1672; *Vetus*, 1696). The first is a vast bibliography of Peninsular and Spanish colonial writers after 1500, with critical evaluations. The second, a history of Peninsular literature from the reign of Augustus to 1500, marks the emergence of modern bibliography and the transformation of literary history into a scholarly discipline. A second edition (1788; vol. 1 of the *Nova* dated 1783), with additions from Antonio's manuscripts, is still consulted.

Antonioni, Michelangelo (b. Sept. 29, 1912, Ferrara, Italy), Italian film director, cinematographer, and producer, noted for his avoidance of "realistic" narrative in favour of character study and a vaguely metaphorical series of incidents. Among his major films are *Le amiche* (1955), *L'avventura* (1959), *L'eclisse* (1962), and *Blow-up* (1966).

Life. Antonioni is recognizably the product of the mild, uneventful plains of northern Italy that form the background for several of

Antonioni

his films. Reserved and unexpansive in manner, he has said that the experience most important to his development as a filmmaker and as a man was his upbringing in a settled, bourgeois, provincial home, with a sufficiency of money; a traditional education; a code of reserve and self-discipline; and the leisure and ease necessary for a detached view of people and of life. He attended school in Ferrara and went to the university at Bologna, though he continued to live at home and commuted daily to his studies. As a child his consuming interests were architecture and painting; at the university he studied classics, then economics and commerce. He also began haunting the cinemas and writing film criticism for a news-

paper in the neighbouring city of Padua. In 1939 he decided to make the cinema his career.

The obvious place to do this was Rome, where Antonioni soon became a staff member of the magazine *Cinema*; he also spent some months studying at a film school. What else he did in his 20s (apart from becoming an amateur tennis champion for northern Italy) remains obscure; his first credited film work dates from his 30th year, when he collaborated on the scripts of some major feature films, one of them Roberto Rossellini's *Pilota ritorna*, and went to France to assist the director Marcel Carné on his wartime production *Les Visiteurs du soir*. In 1943 he began to direct his own first film, a short documentary called *Gente del Po*, but its completion was interrupted by the chaos of Italy's defeat in World War II. For a while Antonioni made his living by translating from the French, then became film critic of the underground paper *Italia libera*, and wrote some unproduced scripts. *Gente del Po* finally appeared in 1947; it was followed by six more shorts and then, in 1950, by his first feature, *Cronaca di un amore*, a rather bitter romance that immediately established him as a talent to be watched.

After that time, Antonioni's life, to the outside world at least, consisted of little more than the production of films. The landmarks are his first great film, *Le amiche* (based on a story by the Italian writer Cesare Pavese), in 1955; his first big international success, *L'avventura*, in 1959; his first film in colour, *Deserto rosso*, in 1964; his first full-length English-language film, *Blow-up*, in 1966; and his first American film, *Zabriskie Point*, in 1970. He was responsible for shaping the career of the actress Monica Vitti, whose exquisite, mysterious presence provided the warming touch of human interest that assured *L'avventura*, despite its puzzling narrative structure and obscurity of motive, its breakthrough to a large international audience. Some mediation of this sort is necessary in Antonioni's films since without it his approach remains too cold and abstract to reach more than a select, esoteric audience. Human beings for him are depicted as moving parts in a pictorially exquisite pattern of moods and atmospheres; they wander around unable to engage in meaningful action, uncommunicative, lost in their dreams, while the outside world mirrors the feelings they never express, their alienation from one another and from the life around them.

Antonioni's critical reputation stood at its highest when the impact of his new, personal vision was most immediate, between *L'avventura* in 1959 and *L'eclisse* in 1962, in both of which a young woman, portrayed by Monica Vitti, unsuccessfully seeks in romance a means of coping with the emptiness of her life. His later films—including *Chung Kuo-China* (1972), *The Passenger* (1974), and *The Mystery of Oberwald* (1980)—did not receive as much acclaim. Antonioni's place in the history of the cinema and in the development of 20th-century sensibility, however, remains secure.

Assessment. One of the cinema's leading aesthetes, Antonioni spearheaded a critical and commercial reaction against the overwhelming acceptance, during post-World War II years, of unvarnished reality as a cinematic ideal. Under his direction the film became a metaphor for human experience, rather than a record of it.

He never structured his films around a traditional plot or a character analysis; it was rather the visual image that became his fundamental vehicle of expression, most noticeably, the modern industrial landscape. After Antonioni, few people saw a water tower or a plastics dump with quite the same unappre-

ciative eyes; in his films a new kind of beauty was revealed in the mechanical jungle of 20th-century urban society. (J.R.T.)

Pierre Leprohon, *Michelangelo Antonioni* (1963), a critical study, with documents and extracts from Antonioni's writings and interviews, John Russell Taylor, *Cinema Eye, Cinema Ear* (1964), includes a critical study of Antonioni, with filmography and bibliography; Ian Cameron and Robin Wood, *Antonioni* (1969), a film-by-film analysis; Michelangelo Antonioni, *Screenplays: Il Grido, L'Avventura, La Notte, L'Eclisse* (Eng. trans. 1963), reading texts of four major works, with an introduction by Antonioni.

Antonius (Latin personal name): *see under* Anthony.

Antony (personal name): *see under* Anthony, except as below.

Antony, Mark, also spelled **MARC ANTHONY**, Latin **MARCUS ANTONIUS** (b. 82/81 BC—d. August, 30 BC, Alexandria), Roman general under Julius Caesar and later triumvir (43–30 BC), who, with Cleopatra, queen of Egypt, was defeated by Octavian (the future emperor Augustus) in the last of the civil wars that destroyed the Roman Republic.

Mark Antony, detail of a marble bust; in the Vatican Museum
Alinari—Art Resource/EB Inc

Early life and career. Mark Antony was the son and grandson of men of the same name. His father was called Creticus because of his military operations in Crete, and his grandfather, one of the leading orators of his day, was vividly portrayed as a speaker in Cicero's *De oratore*. After a somewhat dissipated youth, the future triumvir served with distinction in 57–54 as a cavalry commander under Aulus Gabinius in Judaea and Egypt. He then joined the staff of Julius Caesar, to whom he was related on his mother's side, and served with him for much of the concluding phase of Caesar's conquest of central and northern Gaul and its aftermath (54–53, 52–50). In 51 Antony held the minor office of quaestor, an office of financial administration that gave him a place in the Senate, and he was subsequently elected to the politically influential priesthood of the augurs.

Civil war and triumvirate. In 49, the year in which the Civil War broke out between Pompey and Caesar, Antony became tribune of the people (an official with the traditional function of protecting the plebeians from arbitrary actions of the magistrates) and vigorously supported Caesar in the Senate. He fled from Rome to his patron's headquarters after receiving threats of violence. After Antony had fought in the brief Italian campaign in which Pompey was forced to evacuate the Italian peninsula, Caesar left him in charge of Italy, a post he again occupied in 48–47 as Master of the Horse (the dictator's assistant) after the

decisive battle at Pharsalus (in Thessaly) in which he had commanded Caesar's left wing. Thereafter, because his methods as regent of Italy had displeased Caesar, he was removed from the post and was without employment until 44 when he became consul as the dictator's colleague. After Caesar's murder, he used a variety of methods, including the falsification of the dead man's papers, to control events and to arouse the people against Caesar's assassins, Marcus Brutus and Cassius. In June, Antony was granted a five-year governorship of northern and central Transalpine Gaul (Gallia Comata) and Cisalpine Gaul (northern Italy). Despite his growing power and popularity among the people, the orator Cicero attacked him fiercely in a series of speeches from September 44 to April 43 BC (he never tired of saying that Antony should have been murdered also), and the 19-year-old Octavian, Caesar's great-nephew and adopted son, gradually emerged as a rival. In April 43 a coalition of Octavian, the two consuls of the year, and Decimus Brutus (another of the former conspirators against Caesar) defeated Antony at Mutina (Modena) and compelled him to withdraw into the southern part (Narbonensis) of Transalpine Gaul. There, however, he was joined by a number of leading commanders including Marcus Aemilius Lepidus, who, after Antony, had been Caesar's Master of the Horse. In early November Octavian met Antony and Lepidus in Bononia (Bologna), and the three entered into an official five-year autocratic pact, the second triumvirate (November 43). The enemies of the triumvirs, including the orator Cicero, were proscribed and executed, and in the following year Marcus Brutus and Cassius killed themselves after their defeat at the Battle of Philippi, in which Antony greatly distinguished himself as a commander. The republican cause was now dead.

The triumvirs had agreed to divide the empire; so Antony proceeded to take up the administration of the eastern provinces. He first summoned Cleopatra, the queen of Egypt, to Tarsus (southeastern Asia Minor) to answer reports that she had assisted their enemies. She successfully exonerated herself, and Antony spent the winter of 41–40 as her lover at Alexandria. In spite of the romantic accounts of ancient authors, however, she did not at this stage establish a permanent dominance over him, since he made no move to see her again for more than three years.

Early in 40 he received two pieces of bad news: that his brother Lucius Antonius and his third wife, Fulvia, on their own initiative and without success, had revolted against Octavian, thus setting off the Perusine War (after the central point of the rising, Perugia, the modern Perugia); and that the Parthians, the eastern neighbours of the empire, had invaded Roman Syria. In spite of the latter information, Antony first proceeded to Italy, where he became reconciled to Octavian at Brundisium (Brindisi), and, since Fulvia had died in the meantime, he married Octavian's sister Octavia. The two triumvirs agreed that Herod, who had fled from Judaea to escape the Parthians and their Jewish allies, should be encouraged to retake the country and become its king. In the following year they concluded the short-lived Treaty of Misenum with Pompey's son Sextus Pompeius, who because of his control of wide areas of the Mediterranean had been pirating Roman ships.

Accompanied by Octavia, Antony then proceeded to Athens, where he was enthusiastically greeted and hailed as the New Dionysus, mystic god not only of wine but also of happiness and immortality. In 38 Antony's lieutenant Publius Ventidius won a decisive victory over the Parthians, and, in the following year, Herod was able to reestablish himself at Jerusalem. Meanwhile, however, further differences had arisen between Antony and

Octavian, and, although these were ostensibly settled by the Treaty of Tarentum, which prolonged the triumvirate for a further five years, Antony sent Octavia back to Italy from Corcyra (modern Corfu, or Kérkira) when he left again for the east and arranged for Cleopatra to join him in Syria. Henceforward, apart from his absences on land campaigns, they lived together for the remaining seven years of their lives.

Alliance with Cleopatra. Religious propaganda declared Cleopatra the New Isis, or Aphrodite, to his New Dionysus, and it is possible (but unlikely) that they contracted an Egyptian marriage: it would not have been valid in Roman law since Romans could not marry foreigners. Apart from their undoubted mutual affection, Cleopatra needed Antony in order to revive the old boundaries of the Ptolemaic kingdom (though her efforts to convince him to give her Herod's Judaea failed), and Antony needed Egypt as a source of supplies and funds for his planned attack on Parthia. His invasion, however, of Parthia's ally Media Atropatene (southwest of the Caspian) in 36 BC ended in a retreat involving heavy losses. On his return to Syria, Cleopatra met him with money and supplies. Octavian, exploiting the occasion and the contrast of Antony's failure with the decisive victory he himself—or rather his admiral Agrippa—had won against Sextus Pompeius, sent Octavia to Antony along with troops and provisions. But the soldiers fell far short of the numbers Antony expected (and were owed by his fellow-triumvir), and he then made a future breach between the two leaders almost inevitable by ordering Octavia to return to Rome.

The break was accelerated in 34, when he celebrated a successful expedition to Armenia by appearing in a triumphal procession through the streets of Alexandria, a proceeding regarded by Romans as an impious parody of their traditional Triumph. A few days later he staged a ceremony at which Cleopatra was pronounced Queen of Kings, her son and joint monarch Ptolemy XV Caesar, or Caesarion (for Cleopatra, and now Antony, claimed that Julius Caesar had fathered the boy), was declared King of Kings, and the two sons and a daughter that Cleopatra had borne to Antony were also given imposing royal titles. The exact significance and substantiality of these Donations are disputable, but critics interpreted them as involving the transfer of Roman territories into alien, Greek, hands. In the next year, 33, the Roman leaders launched unprecedented, savage propaganda attacks upon one another, including the production by Octavian of a document (of dubious though possible authenticity) that purported to be a will of Antony favouring the children of Cleopatra and providing for his own burial at Alexandria. In 32 the triumvirate had officially ended, although Antony continued to call himself triumvir on his coins. Both consuls at Rome, however, happened to support Antony, and now, threatened by Octavian, they left for his headquarters, bringing numerous, probably more than 200, Roman senators with them. After Antony had officially divorced Octavia, her brother formally broke off the ties of personal friendship with him and declared war, not against him but against Cleopatra. Antony successively established his headquarters at Ephesus (Selçuk), Athens, and Patras (Pátrai) and marshalled his principal fleet in the gulf of Ambracia (northwestern Greece). More naval detachments occupied a long line of posts along the west coast of Greece. But Octavian's admiral Agrippa, and then Octavian himself, succeeded in sailing from Italy across the Ionian Sea and effecting landings, and Agrippa captured decisive points all along the line.

As Antony lost more ground, the morale of his advisers and fighting forces deteriorated, a process aided by Cleopatra's insistence on

being present at his headquarters against the wishes of many of his leading Roman supporters, thus providing Octavian with fresh propaganda fuel. Because of this lack of unity and the inexperience of Antony's crews, the decisive battle was lost before it ever began. It took place off Actium, outside the Ambracian Gulf, on Sept. 2, 31 bc. Antony suffered the inevitable defeat, but Cleopatra, by pre-arranged plan rather than treachery, broke through the enemy line with her 60 ships (carrying her and Antony's treasury) and, joined by her lover, made for Egypt. It was nearly a year before Octavian reached them there, but soon after his arrival, when resistance proved impossible, first Antony and then Cleopatra committed suicide (August 30 bc).

Personality. Antony was a man of considerable ability and impressive appearance, far more genial than his adversary but not quite equal to Octavian's exceptional efficiency and energy and, in particular, unfit or unwilling to grasp the moment for action. Nevertheless, he was an outstanding leader of men and a competent general, though, in the end, not such a successful admiral as the experienced Agrippa. As a politician, he was astute enough—aided by a talent for florid oratory—but gradually lost touch with Roman feeling and fatally lacked the cold deliberateness of Octavian. Since the latter proved victorious in his struggle for power, it is his interpretation of events, rather than Antony's, that has remained lodged in the history books. Cicero had earlier depicted Antony as a drunken, lustful debauchee—though his adulteries may have been less extensive than Octavian's. More significantly for history, the outcome of the battle off Actium made certain that Octavian's Roman-Italian policy prevailed throughout the empire, and the Antonian theme of Greco-Roman collaboration was not given a trial until the emperor Constantine captured Byzantium three centuries later. (M.Gr.)

Antony Khrapovitsky, original name ALEKSEY PAVLOVICH KHRAPOVITSKY (b. March 17, 1863, Novgorod, Russia—d. Aug. 10, 1936, Sremski Karlovci, Yugos.), Russian Orthodox metropolitan of Kiev, antipapal polemicist, and controversialist in theological and political affairs who attempted an exclusively ethical interpretation of Christian doctrine.

After graduating from St. Petersburg Theological Academy, Antony entered a neighbouring monastery and in 1885 was ordained an Orthodox priest. Consecrated bishop in 1897, Antony was given the jurisdiction of Volhynia, in Ukraine, in 1902, where he suppressed remnants of the Ukrainian Uniate Church (Eastern Catholic) and quelled national aspirations within the Ukrainian Orthodox Church. In 1912 he was selected a member of the Holy Synod, the ruling council of the Russian Orthodox Church, served as archbishop of Kharkov from 1914 to 1917, and became metropolitan of Kiev in 1918.

With the outbreak of the Russian Revolution, Antony participated in the 1917–18 Pan-Russian Orthodox Council and was named one of the three candidates for the Russian patriarchate. After Ukraine declared its inde-

pendence from the tsarist regime, Antony was exiled to Buchach, southwest Ukraine, because of his efforts to prevent Ukrainian autonomy. The Bolshevik occupation of Ukraine forced him to flee to Sremski Karlovci, Yugos., where in 1920 he assumed the leadership of the Russian Orthodox Church in exile.

With a reputation for polemics, Antony vigorously protested papal claims to supremacy over the universal church. According to some of his coreligionists who charged him with heresy, he was influenced by the anti-intellectual moralism of the Russian novelist Fyodor Dostoyevsky. He compiled a *Dictionary of the Works of Dostoyevsky* in 1921 to better integrate Dostoyevsky's ideas with his own.

In his principal ascetical-moral writings, *Concerning the Dogma of Redemption* (the English version appearing in *The Constructive Quarterly*, 1919) and "Essay on the Orthodox Christian Catechism" (1924), he relegated Christ's work to the level of ethical symbolism that would inspire Christian dedication to a moral life.

antpīpit, either of two species of South American birds of the genus *Corythopis* that resemble pipits in size, shape, and coloration. The name antpīpit is sometimes improperly applied to the gnateaters (*Conopophaga*), who were formerly classified with antpīpits in the family Conopophagidae; *Corythopis* is now usually classified with the tyrant flycatchers in the family Tyrannidae (*q.v.*; order Passeriformes).

Antratsyt, also spelled ANTRATSIT, or ANTRACIT, city, Luhansk *oblast* (province), eastern Ukraine. Incorporated in 1938, it is an anthracite-mining town, from which product it takes its name. It is a typical industrial centre on the Donets Coal Basin whose rise was due to the Soviet five-year plans for economic growth. Pop. (1991 est.) 73,000.

Antrim, former (until 1973) county, north-eastern Northern Ireland, occupying an area of 1,176 square miles (3,046 square km), across the 13-mile- (21-kilometre-) wide North Channel from the Mull of Kintyre in Scotland.

Antrim was bounded by the Atlantic Ocean (north), the North Channel and the Irish Sea (east), Belfast Lough (inlet of the sea) and the River Lagan (south), and by Lough (lake) Neagh and the lower River Bann (west).

Its northern and eastern parts were composed of the Antrim Mountains, an ancient basalt plateau of moorland and peat bogs cut by deep glens, ending at its northeastern corner in Fair Head (635 feet [194 m]), a perpendicular cliff. Collapse of the basalt caused the depression holding Lough Neagh, the largest inland lake in the British Isles. Prominent peaks in Antrim included Trostan (1,817 feet), Knocklayd (1,695 feet), and Slieveanorra (1,676 feet); Divis (1,574 feet) is the

highest of the Belfast hills. The basalt reaches the north coast as steep cliffs and, at the Giant's Causeway, forms perpendicular hexagonal columns.

Man probably first came to Ireland through Antrim from western Scotland. Quantities of flint implements, or tools, dating from about 6000 bc occur in the Lough Neagh district. Migrations between Ireland and Scotland were common, especially in the 6th century AD. Scandinavian invaders reached Lough Neagh but made no permanent settlements. Antrim was partially penetrated by Anglo-Norman adventurers during the 12th century and formed part of the earldom of Ulster. Disorders in the late Middle Ages and the invasion by Edward Bruce (later king of Ireland) and his army from Scotland in 1315 caused the decline of English power. Only Carrickfergus remained in English hands until the Tudor period (1485–1603), when attempts were made to colonize the county and many Scots settled there. Although Antrim was not part of the territory involved in the scheme for the plantation of Ulster, it continued to attract many English immigrants.

At one time Carrickfergus was the county town (seat); but, when Belfast became the site of a new county courthouse in 1847, the grand jury also moved there. In 1898, however, Belfast became a county borough, and for a time the county lacked a county town. Until 1973 Ballymena filled that role. In the 1973 administrative reorganization of Northern Ireland, the county was divided into the districts of Moyle, Ballymoney, Ballymena, Larne, Antrim, Carrickfergus, Newtownabbey, and Belfast, and portions of Coleraine, Lisburn, Castlereagh, and Craigavon districts.

Antrim, Irish AONTROIM, town, seat, and district (established 1973), formerly in County Antrim, Northern Ireland. Antrim town is located in the valley of the Six Mile Water stream, at the northeastern corner of Lough (lake) Neagh. In 1798, the town was the scene of a battle in which several thousand nationalist (essentially Presbyterian) insurgents, led by the United Irishmen rebel Henry Joy McCracken, were defeated by the British military. Just north is one of the finest examples of the Irish round (watch) towers, dating from the 10th century; it is 93 feet (28 m) high and 17 feet in diameter. Antrim Castle, built in the 17th century, is evidence of the town's earlier strategic importance. A busy market centre and road junction, Antrim town was formerly an important locale for the linen industry.

Antrim district covers 221 square miles (572 square km) of high, rolling moorlands gradually descending to the Bann Valley and the lowlands along the shoreline of Lough Neagh,

The Antrim Mountains, Northern Ireland

G E Brown—Shostal

the largest inland lake in the United Kingdom. Antrim borders the districts of Ballymena to the north, Newtownabbey to the east, and Belfast and Lisburn to the south and encompasses the villages of Crumlin, Randalstown, Toomebridge, Templepatrick, and Parkgate in addition to the town of Antrim. It supports considerable farming activity, mostly in livestock. Important synthetic-fibre companies were established in the district in the 1970s, and service industries are scattered throughout. Antrim district is traversed by a national highway that extends from Belfast to Randalstown. Belfast's international airport is located at Aldergrove, 7 miles (11 km) south of Antrim town. Pop. (1981) town, 22,342; (1985 est.) district, 45,900.

Antrim, Randal MacDonnell, Marquess and 2nd Earl of, Viscount DUNLUCE (b. June 9, 1609—d. Feb. 3, 1682, Ballymagarry, County Antrim, Ire.), prominent Roman Catholic Royalist during the English Civil Wars who later turned against King Charles I and was employed by Oliver Cromwell.

A grandson of the noted Irish chieftain (of Scottish ancestry) Sorley Boy MacDonnell, he married (1635) the widow of the 1st Duke of Buckingham, a close friend of Charles I. On the outbreak of the Bishops' Wars in 1639, MacDonnell planned an attack on Argyll in Scotland; this project was abortive, as were numerous later schemes by which he hoped to assist the king against Parliament. In May 1643 MacDonnell was captured in County Down by Parliamentary forces and was found to be carrying papers that concerned a planned rising in Scotland by the 5th Earl of Montrose with support from Ireland. MacDonnell escaped after several months' captivity and, on Jan. 26, 1644/45, on Montrose's recommendation, he was created Marquess of Antrim.

He was employed on various missions in Ireland and on the European continent until 1647, when he ceased to support the king's cause. Angry that the 12th Earl of Ormonde was reappointed in 1648 to the lord lieutenancy of Ireland, a position that Antrim had wanted for himself, Antrim offered his services to Cromwell and later served with Parliamentary forces in the sieges of Ross (now New Ross, County Wexford) and Carlow. On going to England in December 1650, he was given a pension in lieu of his confiscated estate.

At the Restoration (1660), Antrim was imprisoned in the Tower of London on a charge of treasonable correspondence (1640–45) with the Confederate Irish Roman Catholics; but through the influence of the queen mother he was pardoned in 1663, and his estates were restored to him in 1665. Upon his death, the marquessate expired, but the earldom of Antrim devolved on his brother.

Antropología, Museo Nacional de (Mexico City): see National Museum of Anthropology.

Antsirabe, town, central Madagascar. It lies on the slopes of the nation's second highest peak, Tsiafajavona, in the Ankaratra Mountains. Thermal springs, associated with ancient volcanism, together with an elevation of 4,000 feet (1,200 m) encouraged the development of a health resort there in 1923. The terminus of a rail line from Antananarivo, the national capital (70 miles [110 km] northeast), Antsirabe serves a region supporting fruit (apples, grapes), dairy, pig, and poultry farms. Industries in the town include spinning and weaving, cigarette making, and food processing. Pop. (1993) 126,062.

Antsiranana, also spelled ANTSEANANA, formerly DIÉGO-SUAREZ, town at the northern tip of Madagascar. Antsiranana, which is situated on a promontory at the south end of

a bay, developed from a French naval base. The local economy still depends on the naval yards and on the transshipment of cargoes be-

The bay and port at Antsiranana, Madagascar
A. Picau—De Wys Inc.

tween coasters and larger vessels. The town's main industry is ship construction and repair. Other industrial products include soap, salt, chemicals, and processed foods. The town is a regional centre (1977) of the University of Madagascar. The airport of Anamakia (6.5 miles [10.5 km] southwest) is served by internal air services.

The region south of Antsiranana is dominated by the forested Tsaratanana Massif, which includes the highest mountain in the country, Maromokotra (9,436 feet [2,876 m]). Most of the people of the region live in the lowlands along the east and west coasts, and a road runs along each coast. The Ankara caves south of Antsiranana are a notable feature of the region. Major crops raised in the locality include rice, cassava, sweet potatoes, peanuts (groundnuts), and sugarcane. Vanilla is grown on a large scale in the southeast. Pop. (1993) 59,040.

Antwerp, Flemish ANTWERPEN, French ANVERS, *province*, northern Belgium, adjoining the Dutch frontier (north). It has an area of 1,107 square miles (2,867 square km) and is drained by the Scheldt (Flemish: Schelde), Dijle, Nete, and Rupel rivers. The *province* of Antwerp was formerly part of the old duchy of Brabant and became part of the French province of Deux-Nèthes after the French occupation of 1795; its present boundaries were established in 1815, although subsequently modified. It is divided into three *arrondissements*, Antwerp, Mechelen, and Turnhout, with the capital at Antwerp.

Kempenland, the plateau region covering most of the northern and central area, is characterized by sand dunes, areas of broom, heather, and poor pasture. There are extensive blocks of coniferous plantations. Around the scattered towns and villages the soil has been fertilized to produce oats, potatoes, vegetables, and fodder for cattle raising. Much of the industry in the *province* is concentrated in the port area around Antwerp; it includes petroleum refining, petrochemical and chemical works, shipbuilding and naval repair, automobile assembly, steel, and nonferrous metallurgy. In Kempenland the opening of the Albert Canal (1930–39) linking Antwerp with Liège has favoured the expansion of the zinc, copper, and nuclear-energy industries. The Zuiderkempen development area is part of a long-range plan for industrial expansion. Kempenland is served by four rail lines.

The southern and western parts of the *province* are hilly, and the soil, although sandy, is more fertile and supports market gardening, sugar-beet cultivation, and dairy farming. Baarle-Hertog (Baerle-Duc), a small enclave in The Netherlands, is administered by Antwerp *province*, the Dutch part being called Baarle-Nassau.

The chief provincial cities are Antwerp, Mechelen, Turnhout, Lier, Herentals, and Mol (the site of the Belgian Nuclear Energy Study

Centre). There are many medieval castles in Kempenland and in the greenbelt around Antwerp. At Tongerlo is the most notable of many old monasteries in the region; the Abbey of Prémontré, founded in 1133, has a modern aspect reflecting its reconstruction in the 17th century. The Natural Reserve of Kalmthout (1968; 2,000 acres [810 hectares]) preserves the natural countryside and has a bird sanctuary. Pop. (2000 est.) 1,643,972.

Antwerp, Flemish ANTWERPEN, French ANVERS, capital of Antwerp *province*, Belgium. It is located 55 miles (88 km) southeast of the North Sea on the estuary formed by the Scheldt (Schelde), Meuse (Maes), and Rhine (Rijn) rivers. It is often identified as the unofficial capital of Flanders, the Dutch- (Flemish-) speaking portion of Belgium. The city is one of the world's major seaports.

A brief treatment of Antwerp follows. For full treatment, see MACROPAEDIA: Antwerp.

The original site of Antwerp on the right (east) bank of the Scheldt River is a vast alluvial plain; since 1923, however, the city's territory has also included land on the river's left bank. Antwerp's contemporary economic life reflects its long history as a major seaport and world trade centre. In addition to shipping and port-related activities, the major manufactures include automobiles, petrochemicals, and electronics. The city is also a centre for diamond cutting.

Antwerp can be divided into three major sections. The old city, with narrow, winding streets, lies within the former confines of the 16th-century fortifications, which were replaced in the 19th century by broad avenues. The 19th-century portions of the city stretch beyond a second set of ring roads, while many newer neighbourhoods lie still farther from the old city and blend into adjacent municipalities.

The Cathedral of Our Lady, begun in the 14th century, is a fine example of Gothic architecture and the largest church in the country. Other examples of Antwerp's rich cultural heritage are preserved in several museums, notably the Rubens House, the Museum Plantin-Moretus, and the Royal Museum of Fine Arts. The city has both state and private institutions of higher learning and is the site of the National Higher Institute and Royal Academy for Fine Arts (1663) and the Royal Flemish Conservatory of Music (1898).

The port complex handles heavy ship and barge traffic. Antwerp is a domestic and international railway centre, and its Deurne airfield handles both freight and passenger flights.

The city almost tripled its population in 1983 with the annexation of several neighbouring municipalities. Area city, 75 square miles (195 square km); metropolitan area, 584 square miles (1,512 square km). Pop. (2000 est.) city, 446,525; (1991) metropolitan area, 1,148,294.

Antwerp Mannerists, the unidentified group of painters working primarily in Antwerp (but also in other Flemish cities) in about 1520 whose works bear certain characteristic features. The paintings are instructive records of an unavailing attempt to combine the Gothic and Renaissance styles and to incorporate disparate Flemish and Italian traditions into the same composition. Exponents of the style frequently painted such subjects as the Adoration of the Magi and the Nativity, both of which are generally represented as night scenes, crowded with figures and illuminated with flickering, often irrational lighting. The Adoration scenes were especially popular with the Antwerp Mannerists, who took delight in the patterns of the elaborate clothes worn by the Magi and the ornamentation of the architectural ruins in which the dramatic confrontation was staged.

Although attempts have been made to identify the individuals responsible for the several

"Adoration of the Magi," centre panel of a triptych by the Antwerp Mannerist painter Jan de Beer, c. 1520(?); in the Brera, Milan

SCALA—Art Resource

stylistic groups, most of the paintings remain attributed to anonymous masters. Characteristic of Antwerp Mannerism are works attributed to Jan de Beer (d. c. 1535), those of the Master of 1518 (Jan van Dornicke), and, to a lesser degree, certain early paintings of Jan Mabuse (d. c. 1532) and Adriaen Ysenbrandt (d. 1551).

Antwerp Zoo, Dutch ZOO ANTWERPEN, zoological garden in Antwerp, Belg., that has one of the largest and most diversified animal collections in Europe. It houses more than 6,000 specimens, including about 300 reptiles and 1,700 fish, which represent more than 1,160 different species. Among the most notable specimens of the mammal collection are the rare Père David's deer and white rhinoceroses. The Antwerp Zoo is perhaps best known for its development of a special display technique for reptile exhibits. This technique involves the use of a cold barrier (*i.e.*, a refrigerated zone), rather than iron bars or glass panels, as a means of containing reptiles in their enclosures.

The Antwerp Zoo was first opened to the public in 1843. It occupies a 10-hectare (25-acre) site in the centre of the city and is administered by the Royal Zoological Society of Antwerp. During the 1920s the zoo gained prominence for breeding the then newly discovered okapi and Congo peafowl. In 1936 the zoo acquired 36 hectares (90 acres) in Planckendael on which it later developed a breeding station for endangered species such as the bongo antelope and Indian rhinoceros.

antyeṣṭi, Hindu funeral rites, varying according to the caste and religious sect of the deceased but generally involving cremation followed by disposal of the ashes in a sacred river. *Antyeṣṭi* rites are the final sacraments (*saṃskāras*) in a series that ideally begins at the moment of conception and is performed at each important stage of a man's life.

At the approach of death, relatives and Brahmans (priests) are summoned, mantras (sacred formulas) and sacred texts are recited, and ceremonial gifts are prepared. After death the body is removed as soon as possible to the cremation grounds, which are usually located on the banks of a river. The eldest son of the

deceased and the officiating priest perform the final cremation rites. For 10 days thereafter, the mourners—the immediate family members—are considered impure and are subject to certain taboos. During this period they perform rites intended to provide the naked soul of the deceased with a new spiritual body with which it may pass on to the next life. Ceremonies include the setting out of milk and water and the offering of rice balls. At a prescribed date, the bones are collected and disposed of by burial or by immersion in a river. Rites honouring the dead, called *śrāddha* (*q.v.*), continue to be performed by the survivors at specified times.

Anu (Akkadian), Sumerian AN, Mesopotamian sky god and a member of the triad of deities completed by Bel (Sumerian: Enlil) and Ea (Enki). Like most sky gods, Anu, although theoretically the highest god, played only a small role in the mythology, hymns, and cults of Mesopotamia. He was the father not only of all the gods but also of evil spirits and demons; Anu was also the god of kings and of the yearly calendar. He was typically depicted in a headdress with horns, a sign of strength.

His Sumerian counterpart, An, dates from the oldest Sumerian period, at least 3000 BC. Originally he seems to have been envisaged as a great bull, a form later disassociated from the god as a separate mythological entity, the Bull of Heaven, which was owned by An. His holy city was Erech, in the southern herding region, and the bovine imagery suggests that he belonged originally to the herders' pantheon. In Akkadian myth Anu was assigned a consort, Antum (Antu), but she seems often to have been confused with Ishtar (Inanna), the celebrated goddess of love.

Anu, Chao, also called ANOU, ANOUVONG, or ANURUTTHARAT (b. 1767—d. January 1829, Bangkok, Siam [Thailand]), ruler of the Lao kingdom of Vientiane who tried unsuccessfully to secure independence for central and southern Laos from its Siamese overlords.

In his youth Anu, along with his brother Inthavong, fought with the Siamese against the Burmese. His military ability and bravery won him the respect and trust of the Siamese, who chose him to succeed Inthavong as king of Vientiane in 1804. In the early years of his reign he strengthened his internal administration and undertook major public works and the enlargement of his capital city. He also cultivated good relations with the neighbouring kingdom of Vietnam, to which he sent tribute every three years (as opposed to annual tribute to Siam).

When the southern Lao principality of Champassak succumbed to internal collapse, Anu persuaded the Siamese to name his son, Chao Yo, to rule there from 1819. Anu now controlled both central and southern Laos, on both banks of the Mekong River, and constructed fortifications throughout the region. He further sought from the northern Lao kingdom of Luang Prabang its neutrality in the conflict that was building with Siam. After an unpleasant stay in Bangkok for the funeral of King Rama III in 1825, Anu returned to Vientiane and organized for rebellion. Believing a false rumour that the British were preparing to attack Siam, he led his armies toward Bangkok, and he managed to get within three days of the Siamese capital by pretending to be rushing to the defense of Siam against the British. His plans for Lao independence leaked out, however, and the Siamese, in a counterattack, captured and sacked Vientiane. By 1828 the rebellion had been quelled.

After receiving inadequate assistance from the Vietnamese, Anu was forced to flee into the forests, but he was captured by a second Siamese expedition and brought to Bangkok, where he was displayed in an iron cage and punished before he succumbed. The Siamese razed Vientiane and transported most of the

population of the central Mekong region across the river into what was later to become northeastern Thailand. With the collapse of Anu's rebellion, the independence of Vientiane came to an end.

Anuak, also spelled ANYWAK, a riverain Nilotic people of the northern Luo language group. About one-fourth of the Anuak live in southeastern Sudan, the remainder in Ethiopia. The Anuak are believed to have migrated from lands east of the African great lakes several centuries ago.

The Sudanese Anuak occupy high ground in savanna grasslands along riverbanks that are flooded annually; separate wet- and dry-season villages are maintained. The Ethiopian Anuak live in forested savanna and along streams in the highlands bordering The Sudan. Because more dry ground is available to the eastern (Ethiopian) Anuak—resulting in more closely connected villages—they have a wider political organization than that afforded by the autonomous villages of the western Anuak. Unlike most Nilotic peoples, the eastern Anuak keep no cattle; instead they fish, hunt, maintain gardens, and rear some sheep and goats.

Through the turbulent 19th and early 20th centuries, the Anuak fought with neighbouring Nuer and resisted colonial occupation. From 1930 the Anuak, represented by chiefs, have participated in the Sudanese administration. They were active participants, however, in the civil war (1955–72) to create an independent black state for the southern Sudanese.

Anuak clans are patrilineal. Lineage members live in the same village, but each village, of 200 to 2,000 people, comprises several unrelated clans. Eastern Anuak traditionally have had a royal clan and a king, while western village headmen have had autonomy. Most Anuak are monogamous.

Anubis, also called ANPU, ancient Egyptian god of the dead, represented by a jackal or the figure of a man with the head of a jackal. In the Early Dynastic period and the Old Kingdom, he enjoyed a preeminent (though not exclusive) position as lord of the dead but was later overshadowed by Osiris.

His particular concern was with the funerary cult and the care of the dead: hence he was reputed to be the inventor of embalming, an art he first employed on the corpse of Osiris.

Anubis (left), painted on a canopic chest, 19th dynasty; in the Archaeological Museum, Florence

Alinari—Art Resource

In his later role as the "conductor of souls," he was sometimes identified by the Greco-Roman world with the Greek Hermes in the composite deity Hermanubis.

anumāna (Sanskrit: "measuring along some other thing," or "inference"), in Indian philosophy, the second of the five means of

knowledge (*pramāṇa*) that enable man to have accurate cognitions. Inference occupies a central place in the Hindu school of logic (Nyāya). This school worked out a syllogism that has the form of an argument rather than a formula and that goes through five stages: (1) the proposition (*pratijñā*, literally "promise"), (2) the ground (*hetu*), (3) the illustration (*udāharaṇa*), (4) the application (*upanaya*), and (5) the conclusion (*niḡamana*). A syllogism is vitiated by a fallacious ground; this is called *hetvābhāsa* ("the mere appearance of a ground"). A number of types of invalid grounds are distinguished: simple error, contradiction, tautology, lack of proof for the ground, and inopportunity. See also *pramāṇa*.

Anura, also called SALIENTIA, order of about 3,900 species of tailless amphibians including the frog and toad (*q.v.*).

Anurādhapura, Sinhalese kingdom centred at Anurādhapura in Sri Lanka (Ceylon) from about the 3rd century BC to the early 10th century AD. Beginning in the 2nd century BC the kingdom of Anurādhapura was plagued by invasions from South India, which increased in later centuries. The South Indians gained actual control of the kingdom several times—in the 2nd century BC, in the 5th century AD, and most notably in the late 10th century, after which Anurādhapura was finally abandoned as the Sinhalese capital in favour of the city of Polonnaruwa. In addition to the South Indian invasions, the kingdom was often beset with internal strife among warring Sinhalese clans, each wishing to establish its own dynastic line. In these struggles the insurgent clan frequently sought alliance with a South Indian kingdom or hired South Indian mercenaries. The most prominent Anurādhapurian dynasties were the Vijayan (3rd century BC–1st century AD) and the Lamakaṇṇa (1st–4th century AD and 7th–10th century).

During the more than 1,000 years of its existence, the kingdom of Anurādhapura developed a high degree of culture, especially manifest in its art and architecture. Because of its geographic situation in the northern dry zone of Ceylon, it developed a remarkably complex system of irrigation, considered by many scholars to be its major achievement.

Anuradhapura, city, north-central Sri Lanka (Ceylon). It is situated along the Aruvi Aru River. The old section of Anuradhapura, now preserved as an archaeological park, is the best known of Sri Lanka's ancient ruined cities; in the immediate vicinity are huge bell-shaped

Thūpārāma dagoba (Buddhist religious building), Anuradhapura, Sri Lanka

Harrison Forman

dagobas (Buddhist commemorative shrines, or stupas) built of small sun-dried bricks, as well as temples, sculptures, palaces, and ancient drinking-water reservoirs. The city also contains an ancient pipal tree that is believed to have originally been a branch of the Bo tree at Buddh Gayā, under the shade of which Gau-

tama attained to buddhahood. The Bo tree branch was planted at Anuradhapura about 245 BC, and it may be the oldest tree in existence of which there is any historical record.

Anuradhapura was founded in the 5th century BC and was the Sinhalese capital of Sri Lanka from the 4th century BC until the 11th century AD, when invasions from South India forced the shifting of the capital. The city was abandoned and overrun by jungle; in the 19th century the British rediscovered it, and it became a Buddhist pilgrimage centre. The revival of the city began in earnest in the 1870s. The contemporary city, much of which was moved during the mid-20th century to preserve the site of the ancient capital, is a major road junction of northern Sri Lanka and lies along a railway line. The headquarters of the Archaeological Survey of Ceylon is in Anuradhapura. Pop. (1990 est.) 37,000.

anus, plural ANUSES, or ANI, terminal portion and opening of the digestive tract of vertebrates and many invertebrates. In humans it comprises the anal canal and opening, the end of the large intestine. Its function is to excrete fecal material from the body. Numerous blood vessels surround the anal canal and may be subject to enlargement and rupture; this condition, commonly called a hemorrhoid (*q.v.*), or pile, may cause pain, bleeding, and projection of the vessels from the anal opening. See also anal canal; rectum.

Anvarī, pseudonym of AWHAD AD-DĪN 'ALĪ IBN VĀHĪD AD-DĪN MUḤAMMAD KHĀVARĀNĪ, also called AWHAD AD-DĪN MUḤAMMAD IBN MUḤAMMAD, or AWHAD AD-DĪN 'ALĪ IBN MAHMŪD (b. c. 1126, Abivard, Turkistan [now in Turkmenistan]—d. c. 1169, Balkh, Khorāsān [now in Afghanistan]), poet considered one of the greatest panegyrists of Persian literature. He wrote with great technical skill, erudition, and a strong satirical wit.

Anvarī was not only well versed in Persian and Arabic literature but was skilled in such other fields as geometry, astronomy, and astrology. His work is replete with extremely erudite and obscure allusions, making his poems difficult to understand without some accompanying commentary.

Anvarī was a prolific writer who especially excelled in the art of the qasida (ode) and ghazal (lyric). His odes display great formal virtuosity, while his comparatively simple lyrics are noted for their tenderness and charm. In his *divan*, or collected poems, there are 632 pages of qasidas and ghazals, rubaiyat (quatrains), *qiṣ'ahs* (shorter poems), and *maṣnavīs* (couplets). Of his life relatively little is known. Rather early in his career he certainly served as court poet of Sultan Sanjar of the Seljuq dynasty. Later he composed biting and satirical works sharply criticizing all aspects of the social order. His longest poem is a lament on the devastation wrought in Khorāsān (largely in northeastern Iran) in 1153 by invading Oğuz tribesmen.

Anvarī did not think poetry the loftiest skill and scorned the life of a court poet. But he noted resentfully and sarcastically that patronage was the only means to acquire adequate wealth. Thus he remained a court poet until later in life, when circumstances forced him to follow the more independent and probably much-preferred course of the scholar, and he ended his life in quiet seclusion.

anvil, iron block on which metal is placed to be shaped, originally by hand with a hammer. The blacksmith's anvil is usually of wrought iron, but sometimes of cast iron, with a smooth working surface of hardened steel. A projecting conical beak, or horn, at one end is used for hammering curved pieces of metal. Sometimes the other end has a beak with a rectangular section. Tools such as the anvil cutter or chisel can be placed cutting edge uppermost into a holder consisting of a square hole in

the anvil's surface. When power hammers are used, the anvil is supported on a heavy block,

Blacksmith's anvil

which in turn rests on a strong foundation of timber and masonry or concrete.

Anville, Jean-Baptiste Bourguignon d' (b. July 11, 1697, Paris, France—d. Jan. 28, 1782, Paris), French geographer and cartographer who greatly improved the standards of map-making.

From an early age d'Anville continued the reform of French cartography begun by Guillaume Delisle, but he was also a reputable classical scholar, and many of his memoirs and maps relate to ancient and medieval geography. He displayed exceptional judgment in his choice and use of past authorities and a detailed knowledge of measures of distance, and he adjusted his measurements where possible to astronomically determined positions. His first important map was that of China, prepared from the surveys of the Jesuits. First issued in 1735, it later was published as the *Nouvel atlas de la Chine* ("New Atlas of China") in 1737. His map of Italy (1743) corrected numerous errors in the accepted maps of that country. Other important maps were of Africa (1749), Asia (1751), India (1752), and the world in hemispheres (1761). From the contemporary map of Africa, d'Anville removed many of the conventional and largely fictitious features of the interior, and his representation stood until the great explorations of the 19th century. His *Atlas général*, first published in 1743, was frequently revised. D'Anville was appointed first geographer to the king of France in 1773.

anxiety, a feeling of dread, fear, or apprehension, often with no clear justification. Anxiety is distinguished from true fear because the latter arises in response to a clear and actual danger, such as one affecting a person's physical safety. Anxiety, by contrast, arises in response to apparently innocuous situations or is the product of subjective, internal emotional conflicts the causes of which may not be apparent to the person himself. Some anxiety inevitably arises in the course of daily life and is normal. But persistent, intense, chronic, or recurring anxiety not justified in response to real-life stresses is usually regarded as a sign of an emotional disorder. When such an anxiety is unreasonably evoked by a specific situation or object, it is known as a phobia (*q.v.*). A diffuse or persistent anxiety associated with no particular cause or mental concern is called general, or free-floating, anxiety.

There are many causes (and psychiatric explanations) for anxiety. Sigmund Freud viewed anxiety as the symptomatic expression of the inner emotional conflict caused when a person suppresses from conscious awareness experiences, feelings, or impulses that are too threatening or disturbing to live with. Anxiety is also viewed as arising from threats to an individual's ego or self-esteem, as in the case of inadequate sexual or job performance. Behavioral psychologists view anxiety as an unfortunate learned response to frightening events in real life; the anxiety produced becomes attached to the surrounding circumstances associated with that event, so that those circumstances come to trigger anxiety in the person independently of any frightening event.

An anxiety disorder may develop where anxiety is insufficiently managed, characterized by a continuing or periodic state of anxiety

or diffuse fear that is not restricted to definite situations or objects, and is generally classed as one of the psychoneuroses (neuroses). The tension is frequently expressed in the form of insomnia, outbursts of irritability, agitation, palpitations of the heart, and fears of death or insanity. Fatigue is often experienced as a result of excessive effort expended in managing the distressing fear. Occasionally the anxiety is expressed in a more acute form and results in physiological concomitants such as nausea, diarrhea, urinary frequency, suffocating sensations, dilated pupils, perspiration, and rapid breathing. Similar symptoms occur in several physiological disorders and in normal situations of stress or fear, but they may be considered neurotic when they occur in the absence of any organic defect or pathology and in situations that most people handle with ease.

Other types of anxiety-related disorders include hypochondriasis, hysteria, obsessive-compulsive disorders, phobias, and schizophrenia.

Anyang, city, Kyōnggi *do* (province), northwestern South Korea, 19 mi (31 km) southwest of Seoul. Given the status of a municipality in 1973, it has become the largest industrial satellite of Seoul. Industries include brewing and the manufacture of textiles, pottery, paper, and bricks. The country's largest motion-picture studio is located there. Among the city's historical remains are two temples, Yōmbul-am and Jūngcho-sa, both built in the 9th century. Pop. (1995) 591,106.

Anyi, also spelled **AGNI**, African people who inhabit the tropical forest of the eastern Ivory Coast and Ghana and speak a language of the Kwa branch of the Niger-Congo family. About the middle of the 18th century most of the Anyi were expelled from Ghana by the Ashanti and migrated westward.

The Anyi, living in neighbourhoods of dispersed homesteads, are shifting cultivators, producing food crops (yams, manioc, and plantains), as well as the cash crops (coffee and cacao) from which they derive most of their income.

The traditional organization consisted of small states, with a social hierarchy comprising four strata: a prince and others of royal blood, village chieftains, freemen, and (formerly) slaves and their descendants. The village chief is chosen from the family that holds the hereditary, ceremonial stool; he is elected by that family and the village notables.

The traditional systems of inheritance and succession are based on matrilineal descent, though a married couple resides in the vicinity of the husband's family. This system produces considerable tension, increased by the development of cash-crop plantations, because, although a young man usually works with his father, he generally will not inherit the plantation on which he works. Fear of sorcery is commonly a result of this tension.

Although the Anyi have come to accept much of European material culture, the traditional elements of their social structure remain effective as a basis for everyday political organization.

Anyte (fl. early 3rd century BC, Tegea, Arcadia), Greek poet of the Peloponnesus who was so highly esteemed in antiquity that in the well-known *Stephanos* ("Garland"), a collection compiled by Meleager (early 1st century), the "lilies of Anyte" are the first poems to be entwined in the "wreath of poets." Anyte's fame persisted, and Antipater of Thessalonica, writing during the reign of Augustus (27 BC–AD 14), called her "a woman Homer" and placed her in a list of nine lyric poetesses. Of 24 extant epigrams assigned to her, 20 are believed to be genuine. In her dedicatory epigrams her verse is akin to that of Theocritus and Leonidas, her contemporaries. Her dedications for fountains and to the nymphs of

the springs show the Greek feeling for a quiet landscape that is so often illustrated in the Greek Anthology. She wrote epitaphs, perhaps literary rather than for actual use, on various animals. She gives no suggestion of herself in her poems and never employs the theme of love. Her love of nature and interest in animals mark her as typical of the early years of the Hellenistic period.

Anywak (people): see Anuak.

ANZAC, abbreviation of **AUSTRALIAN AND NEW ZEALAND ARMY CORPS**, combined corps that served with distinction in World War I. The corps is best known for its heroic service in the ill-fated 1915 Gallipoli Peninsula campaign, an attempt to capture the Dardanelles from Turkey. In 1916 ANZAC infantry units were sent to France, where they took part in some of the bloodiest actions of the war. The cavalry units were assigned to the Middle East. ANZAC ceased to be an official designation after the separation of the Australian and New Zealand forces in 1917. In Australia and New Zealand, ANZAC Day—April 25 (the date of the Gallipoli landing)—has been a major occasion for expressing national sentiment.

Anzali, Bandar-e, formerly **ENZELI, BANDAR-E PAHLAVĪ, or PAHLAVĪ**, principal port and a resort, northern Iran, on the Caspian Sea, connected with Māzandarān, Azerbaijan, and Tehrān by road. The population includes Russians, Armenians, Caucasians, and Turks.

Founded in the early 19th century, the town lies on both sides of the entrance to Mordāb Lagoon. It was occupied by the Russians in 1920; they declared a Soviet Republic of

Wharf at Bandar-e Anzali, Iran
Fred J. Maroon—Photo Researchers

Gilān, but that entity collapsed in 1921. The port lies in the channel between two sandy peninsulas; Ghāziān Peninsula, to the east, has an airfield. The channel is quite irregular in depth. The entrance is protected by two breakwaters, and dredging is necessary. Port installations are mainly on the eastern side. There is a small wharf, an oil depot, and a fishery station. During World War II the port was modernized, and traffic greatly increased as a consequence of the U.S. lend-lease program for the Soviet Union. Pop. (1996) 98,544.

Anzan (ancient city, Iran): see Anshan.

Anzengruber, Ludwig (b. Nov. 29, 1839, Vienna—d. Dec. 10, 1889, Vienna), Austrian playwright and novelist who won acclaim for his realistic plays of peasant life.

After working for a time as an actor, Anzengruber published an anti-clerical drama, *Der Pfarrer von Kirchfeld* (1870; "The Pastor of Kirchfeld"), which was a great success. Except for the melancholy *Der Meineidbauer* (1872; "The Farmer Forsworn"), most of his plays were gay and witty comedies set among the people of small towns; they include *Die Kreuzelschreiber* (1872; "The Cross Makers"), *Der G'wissenswurm* (1874; "The Worm of Conscience"), and *Doppelselbstmord* (1876; "Double Suicide"). He wrote a problem play, *Das vierte Gebot* (1878; "The Fourth Commandment"), and also novels: *Der Schand-*

fleck (1877, revised 1884; "The Stain"), *Der Sternsteinhof* (1884; "The Sternstein Farm"), and other tales of village life.

Anzhero-Sudzhensk, city, Kemerovo *oblast* (province), Russia, on the Trans-Siberian Railroad at the northern limit of the Kuznetsk Coal Basin. Coal mining, begun early in the 20th century, expanded rapidly after 1928, when the townships of Anzherka and Sudzhenka were amalgamated, to be given city status in 1931. Other industries produce pharmaceutical goods, mining machinery, and window glass. Anzhero-Sudzhensk has chemical and medical institutes and a teachers college. Pop. (1997 est.) 101,000.

Anziku, Kingdom of, also called **KINGDOM OF TEKE, or KINGDOM OF TYO**, historic African state on and north of the Congo (Zaire) River in the vicinity of Malebo Pool. The Teke people lived on the plateaus of the region from early times. It is not known when they organized as a kingdom, but by 1600 their state was a rival of the Kongo kingdom south of the river. Controlling the lower Congo River and extending northwest to the upper Kouilou-Niari basin, Anziku was situated to dominate inland trade, especially the trade in slaves. Traditional crafts were gradually abandoned in favour of products imported from Europe in exchange for slaves. In 1880 King Iloo signed a treaty with the French colonialist Pierre Savorgnan de Brazza, making Anziku a French protectorate. Eleven years later (1891) it became the French (Middle) Congo. Anziku's historic territory now constitutes the central part of the People's Republic of the Congo and includes the site of Brazzaville, the national capital.

Anzilotti, Dionisio (b. Feb. 20, 1867, Pescia, Italy—d. Aug. 23, 1950, Pescia), Italian jurist who was one of the main founders of the so-called positive school of international law, a legal philosophy advocating a sharp distinction between the legal and the political and moral aspects of international relations.

In 1906 Anzilotti was cofounder of the *Rivista di diritto internazionale* ("International Law Review"). He was professor of law at the universities of Palermo, Bologna, and Rome (1911–37). In 1921 he was appointed a judge of the Permanent Court of International Justice of The Hague, where he presided from 1928 to 1930.

Anzio, Latin **ANTIUM**, town, Roma province, Lazio (Latium) region, Italy, on a peninsula jutting into the Tyrrhenian Sea. Of uncertain origin, it was founded, according to legend, by Anteias, son of the Greek chieftain Odysseus, and the enchantress Circe. It was a stronghold of the Volsci, an ancient people prominent in

the 5th century BC, and was older than Rome, which conquered it in 338 BC. Antium became an all-season resort where many wealthy Romans owned villas. Augustus, the first Roman emperor, was proclaimed "father of the Roman nation" there, and the emperors Caligula and Nero were born there. A key commercial centre under the Volsci, its importance increased after AD 59, when Nero built a port there. The town was destroyed by the Saracens in the early European Middle Ages and was virtually deserted until a new port to the east of the old one was built by Pope Innocent XII in 1698.

Anzio was the scene of heavy fighting late in World War II. On Jan. 22, 1944, the Allies achieved what probably was the most complete tactical surprise of the war by landing in excess of 36,000 troops and 3,000 vehicles before midnight, securing a beachhead only 37 miles (60 km) from Rome. However, the Allied force took so long—most of a week—to consolidate its position that German Field Marshal Albert Kesselring was able to surround the beachhead, keeping its eventual force of six Allied divisions penned there while he mounted a succession of massive attacks on them during February. Only in late May, when Kesselring withdrew most of his troops, were the Allies able to break out of the beachhead (May 25); then the Allied force greatly facilitated the advance on Rome and its capture. Casualties during the four-month operation approximated 25,000 for the Allies and 30,000 for the Axis forces.

Anzio's extensive Roman remains include the ruins of the port, a theatre, and Nero's villa, where valuable works of art, including the famous Greek statue of Apollo Belvedere, were found.

Anzio is now a seaside resort with long sandy beaches and a small port for yachts and fishing boats. It is connected with the main Rome-Naples railway by a branch line from Campoleone. Fishing is the chief industry; there is also a frozen fish processing plant and a soap and detergent factory. Pop. (1999 est.) mun., 42,734.

Anzoátegui, *estado* ("state"), northeastern Venezuela. It is bounded north by the Caribbean Sea, east by Monagas state, south by the Orinoco River, and west by Guárico state. Most of Anzoátegui's area lies in the Llanos (plains). The coastal range tapers off to form the Barcelona Gap near the state capital, Barcelona, a cattle- and coffee-shipping centre on the Neverí River. Cattle raising has been important in the locality for generations, but agriculture, mostly confined to the highland valleys, is relatively insignificant. Petroleum was discovered about 1930, and by the late 20th century Anzoátegui produced about one-tenth of Venezuela's oil. The Orinoco Heavy Oil Belt is the site of extensive oil exploration. Pipelines transport natural gas to Caracas, Maracay, Valencia, and Puerto La Cruz, and coal is mined at Naricual. Manufacturing has become important in the Barcelona-Guanta-Puerto La Cruz complex. The state's highway network is extensive. Area 16,700 square miles (43,300 square km). Pop. (1997 est.) 1,077,435.

ANZUS Pact, formally PACIFIC SECURITY TREATY, security treaty between Australia, New Zealand, and the United States that was signed in San Francisco, Calif., on Sept. 1, 1951, for the purpose of providing mutual aid in the event of aggression and for settling disputes by peaceful means. It came into force in 1952. The three countries' initials provided the acronyms for the treaty and the organization that grew out of it. The United States offered the pact to Australia as compensation for the prospect of Japanese rearmament. Under

the terms of the treaty, the three nations maintained a consultative relationship with each other and strove to ensure their collective security in the Pacific region.

In the mid-1980s New Zealand instituted an antinuclear policy, one of whose provisions was the banning of nuclear-armed vessels from its ports, including those of the U.S. Navy. In response, the United States formally suspended its treaty obligations to New Zealand in 1986 and reduced the two countries' military ties. The three nations remained formal parties to the treaty, but in practical terms ANZUS was inoperative from then on.

Aoba, also spelled *OWA*, volcanic island of Vanuatu, in the southwestern Pacific Ocean, 30 miles (50 km) east of Espiritu Santo. Its 154-square-mile (399-square-kilometre) area is dominated by a 4,500-foot (1,400-metre) peak with a lake in its crater, which was last active about 1870. The headquarters of the Melanesian church is located at Lolowai, a good harbour on the east coast. The island has a hospital and airstrips and exports copra. Pop. (1989) 8,583.

Aod (Old Testament hero): *see* Ehud.

AOL Time Warner Inc., the largest media and entertainment conglomerate in the world. Its products include magazines, books, music, motion pictures, online services, and broadcast and cable television programming and distribution. Its headquarters are in New York City.

Warner. Warner Brothers Pictures, Inc. (*q.v.*), was incorporated in 1923 in Los Angeles by Polish immigrant brothers Harry, Albert, Sam, and Jack Warner. In 1927 Warner Brothers introduced music and dialog with the first "talkie" motion picture, *The Jazz Singer*. The company was one of the leading studios throughout the 1930s and '40s.

During the 1950s, movies faced growing competition from television, which also presented new opportunities for Warner Brothers, where the hit series *Maverick* (1957) and *77 Sunset Strip* (1958) were made. In 1967 Jack Warner sold his remaining stake in the company to Seven Arts Productions. Two years later, Warner Bros.-Seven Arts, Inc., was bought by Kinney National Services, Inc., and became part of the newly named Warner Communications Inc. (WCI).

Kinney started business as a funeral home company in New Jersey. Steve Ross, who started with Kinney after marrying the owner's daughter, was co-chief executive officer (CEO) from 1969 to 1972, when he became the sole CEO, president, and chairman of WCI. Following an aggressive acquisition strategy, WCI soon encountered financial reversals, culminating in a \$500 million loss in 1983. By 1985 Ross had refocused WCI on its cable television operations, which had remained profitable. Warner Cable had begun in 1972, and in 1979 WCI had entered a joint deal with American Express Company, creating Warner-Amex cable. The business thrived and WCI bought out its partner for \$400 million in 1985. In 1987 Ross began talks with the president of Time Inc., Nicholas Nicholas, about merging the two companies.

Time. *Time* magazine first appeared on March 3, 1923, and sold 9,000 copies. Its founders, Briton Hadden and Henry R. Luce (*q.v.*), sought readers among the 1 million college-educated citizens in the United States at the time. The magazine made a modest \$700 profit in its second year of publication; by 1928 its profits were \$125,000 on a circulation of 200,000. In 1930 the company launched *Fortune*, a business monthly, and in 1936 *Life*, a photojournalism weekly that became one of the nation's most popular periodicals until its slow demise throughout the 1970s. In 1954 the company began the weekly *Sports Illustrated*. In the 1960s Time Inc. started a book division,

Time-Life Books, and acquired Little, Brown & Company, one of the nation's oldest publishers. In 1974 the company started *People*, a weekly focused on personalities that was an outgrowth of the "People" section in *Time*.

Time Inc. first moved into the broadcast and entertainment industry in the 1950s, but in the 1970s sold its broadcast holdings to focus exclusively on cable television—in 1972 founding Home Box Office (HBO).

Time Warner. By the time Ross and Nicholas began their merger talks, Time Inc. was the third largest cable operator in the country, including its 23 percent stake in Turner Broadcasting Systems Inc. (TBS). The merger that created Time Warner was completed in 1989. Ross shared CEO duties with Nicholas until early 1991, when Nicholas left the company. From February 1992 until his death in December, Ross again served as co-CEO, with Gerald (Jerry) Levin, who then became sole CEO of Time Warner Inc.

Throughout the 1990s, Time Warner expanded into new markets, including a Spanish-language version of *People* and a children's edition of *Time*. The WB, a broadcast television network founded by Time Warner, first aired in 1995. In 1996 the company acquired the outstanding shares of TBS, which also owned the Warner Bros. film archive and the Atlanta Braves and Atlanta Hawks sports teams. In late 1999 Time Warner began merger talks with America Online (AOL).

AOL. AOL's roots start in 1982 when Control Video Corporation offered online services to users of Apple II and Commodore 64 computers. In 1985 the company became Quantum Computer Services Inc. (QCS). America Online began as a special QCS service dedicated to users of the Apple Macintosh computer.

In 1991 QCS named Steve Case president, then its CEO. That year the company changed its name to America Online and became a public company in 1992. In 1994 AOL launched an Internet (*q.v.*) division, and by the next year it was the leading Internet service provider. In 1997 more messages were exchanged over AOL every day than were delivered by the U.S. Postal Service that year.

The merger between AOL and Time Warner received final shareholder and regulatory approval in 2001. Case was named chairman of the new company and Levin became CEO.

(Mk.H.)

Aomori, northernmost *ken* (prefecture) on the island of Honshu, Japan. It is bordered by the Pacific Ocean (east), the Tsugaru Strait (north), and the Sea of Japan (west). The peninsulas of Tsugaru and Shimokita enclose Mutsu Bay. Aomori has a relatively poor agricultural economy that is handicapped by long, cold, snowy winters and poor drainage. Rice and Japan's largest apple crop are grown in the west, while the east specializes in dry grains and potatoes. Horse breeding for military use has long given way to beef cattle and dairy farming. Most large-scale manufacturing is found in Hachinohe, in the southeast. In the mountainous interior are some of Japan's finest timber stands, mostly in national forests. Coastal and deep-sea fishing operations centre on Hachinohe, the leading fishing port, and Aomori. Area 3,714 square miles (9,619 square km). Pop. (1999 est.) 1,475,439.

Aomori, city and capital of Aomori *ken* (prefecture), Japan, located on Aomori Bay. One of Japan's most important transportation centres, it is the terminus of both northern Honshu rail lines and railroad ferry services across the Tsugaru Strait to Hakodate, on Hokkaido. The Tohoku Highway and Seikan Tunnel facilitate communication between Hokkaido and Honshu. Strong winter winds make extensive breakwaters necessary in Aomori's artificial harbour, which ships lumber and fish and is noted for coastal trade. Pop. (1995) 294,167.

Aornos, Siege of (327 BC), conflict in which Alexander the Great seized a natural stronghold blocking his route to India. Aornos is evidently modern Pir Sarāi, a steep ridge a few miles west of the Indus and north of the Buner rivers in modern Pakistan. Unable to storm the rock, Alexander seized the hill opposite and threatened the Indians' encampment with his catapults. They retreated but were caught, and many were slaughtered.

aorta, in vertebrates and some invertebrates, the blood vessel (or vessels) carrying blood from the heart to all the organs and other structures of the body.

For a depiction of the aorta in human anatomy, shown in relation to other parts of the body, see the colour Trans-Vision in the PROPAEDIA: Part Four, Section 421.

At the opening from the left ventricle into the aorta is a three-part valve that prevents back-flow of blood from the aorta into the heart. The aorta emerges from the heart as the ascending aorta, turns to the left and arches over the heart (the aortic arch), and passes downward as the descending aorta. The left and right coronary arteries branch from the ascending aorta to supply the heart muscle. The three main arteries branch from the aortic arch and give rise to further branches that supply oxygenated blood to the head, neck, upper limbs, and upper part of the body. The descending aorta runs down through the posterior centre of the trunk past the heart, lungs, and esophagus, through an opening in the diaphragm, and into the abdominal cavity.

In the chest the aorta, as it descends, gives off branches to (1) the pericardium, the sac that encloses the heart, (2) the connective tissues of the lungs, (3) the bronchi, which carry air from the windpipe into the lungs, (4) the esophagus, (5) part of the diaphragm, and (6) the chest wall.

In the abdominal cavity the aorta branches to supply blood to the stomach, liver, pancreas, spleen, small and large intestines, kidneys, reproductive glands, and other organs. At the level of the fourth lumbar vertebra, which is about even with the top of the hip bones, the aorta divides into the right and left common iliac arteries, the principal arteries to the legs.

Aosta, city, capital of Valle d'Aosta region, northwestern Italy, at the confluence of the Buthier and Dora Baltea rivers and commanding the Great and Little St. Bernard pass roads, north-northwest of Turin. It was a stronghold of the Salassi, a Celtic tribe that

Aosta retains the walls, two gates, and the street plan of its Roman predecessor, as well as a triumphal arch in honour of Augustus and remains of the theatre, the amphitheatre, and the road from Eporedia (modern Ivrea). The rectangular street plan, laid out in equal blocks (*insulae*), is an outstanding example of Roman formal city planning. Of later monuments, the cathedral is notable for its treasury and 12th-century floor mosaics, and the collegiate church of S. Orso for its Romanesque cloisters and Gothic choir stalls. Aosta is a commercial centre and has a metallurgical industry. Pop. (1999 est.) 34,741.

aoudad, also called BARBARY SHEEP (*Ammotragus lervia*), north African sheep, family Bovidae (order Artiodactyla). The only wild sheep in Africa, the aoudad stands about 102 centimetres (40 inches) at the shoulder. It has a fringe of long, soft hair hanging from its

Aoudad, or Barbary sheep (*Ammotragus lervia*)

William McKinney—The National Audubon Society Collection/Photo Researchers

throat and forequarters and has semicircular horns that curve outward, back, and then inward over the neck. Both fringe and horns are more pronounced in the male. The aoudad lives in dry, mountainous or broken country and associates in small family groups. It can go without water for about five days. When threatened, the aoudad stands motionless and is concealed by its tawny brown coat, which blends with the surrounding rocks.

Aouelloul Crater, large crater located 28 mi (45 km) southwest of Chinguetti, Mauritania, and thought to be of meteoritic origin. Discovered by air in 1951, it is 833 ft (250 m) in diameter and 33 ft in depth. A large amount of fused silica glass has been found in the area, but only one small meteorite fragment has been recovered from the crater.

Aozou, also spelled AOZOU, town and military post in Tibesti, northern Chad. Military conflict plagued the town and the surrounding region after Chad became independent in 1960. As in the rest of Tibesti, the Muslim Teda nomads of the area resisted the rule of

N'Djamena (then called Fort Lamy), the capital of Chad, and French troops remained to govern northern Chad until 1965. Aozou was one of the French bases. After 1965 the central government of Chad continued to maintain a garrison at Aozou. In 1968 a group of Teda rebels attacked and killed most of the soldiers stationed there. Four years later Libyan troops captured the post and began a long-term occupation.

Apa Tani, tribal people of Arunāchal Pradesh (former North East Frontier Agency), a mountainous state in the extreme northeast of India. They speak a Tibeto-Burman language of the Sino-Tibetan family and numbered about 13,100 in the 1970s.

Unlike other tribes in the area, the Apa Tani practice a settled wet rice (paddy) agriculture. The typical household consists of a husband and wife and their unmarried children. Their society is formed of clans, of which there are two classes, ruling and plebeian. Representatives of the clans compose the village council. They believe in spirits associated with nature.

Apabhramśa language, literary, primarily poetic language that reflects a late stage of Middle Indo-Aryan, immediately prior to Modern Indo-Aryan (c. 12th century). Apabhramśa literature includes major Jaina works. Though a literary language, Apabhramśa shows developments that must have taken place in spoken dialects. In early times, the term Apabhramśa referred to usage considered corrupt, including Middle Indo-Aryan usage (Apabhramśa is Sanskrit for "departure from correct speech"). Some authorities class Apabhramśa as a Prākṛit language (*q.v.*). Moreover, as has been recognized by various authorities, including the prosodist Rudrata (c. 800), Apabhramśa showed dialectal differences.

Apache, farmer-raider Indians of the North American Southwest who, under such leaders as Cochise, Mangas Coloradas, Geronimo, and Victorio, figured largely in the history of the region during the latter half of the 19th century. Their domain extended over what is now east central and southeastern Arizona, southeastern Colorado, southwestern and eastern New Mexico, western Texas, and, in Mexico, northern Chihuahua and Sonora states. This distribution is a recent one. The ancestors of the Apache (and the Navajo) apparently were from the far north, for the Apachean languages are distantly related to other Athabascan languages spoken in Canada. These ancestors probably did not reach the Southwest until AD 1000 or later. Some Apachean peoples are known to have been in the Southwest prior to the 15th century, but as late as 1700 Plains Apache farmers were still living along the Dismal River in Kansas. With the introduction of the horse, these and other Plains Apache were severely pressed south and west by the Comanche and Ute.

Ruins of Roman theatre, Aosta, Italy

Marzan—SCALA from Art Resource/EB Inc

was subdued by the Romans in 25 BC, and a Roman town (Augusta Praetoria) was founded there by Augustus in 24 BC. A bishopric from the 5th century, the town was always the most important centre of the Valle d'Aosta; it became the regional capital in 1945. It was the birthplace of St. Anselm (1033/34–1109), archbishop of Canterbury.

Geronimo (right) and three of his warriors, photographed in their camp by C.S. Fly in 1886

By courtesy of the Smithsonian Institution National Anthropological Archives, Bureau of American Ethnology Collection

Culturally, the Apache are divided into Eastern Apache, which include the Mescalero, Jicarilla, Chiricahua, Lipan, and Kiowa Apache, and Western Apache, which include the Cibecue, Mimbreno, Coyotero, and Northern and Southern Tonto or Mogollon Apache. Characteristic of both Eastern and Western Apache, with the exception of the Kiowa Apache (see Kiowa), was the lack of a centralized tribal organization. The band, an autonomous collection of small local groups within a given locality, was the primary political unit as well as the primary warring and raiding unit. The strongest headman of the local groups was recognized as an informal chief, and several bands might be united under one leader. Chieftainship was thus not generally hereditary.

The Apache subsistence pattern was based partly on hunting and on gathering wild plant foods, partly on farming, and partly on raiding; but the proportion of each varied greatly from tribe to tribe. The Jicarilla (*q.v.*) farmed fairly extensively, growing maize and other vegetables, but also had adopted part of the Plains Indians reliance on bison hunting. The Lipan of Texas, who were probably originally a band of Jicarilla, had largely given up farming and were, therefore, more mobile than the Jicarilla. The Mescalero (*q.v.*) were influenced by the Plains Indians, but their chief food staple was the mescal plant (hence the name Mescalero). The Chiricahua (*q.v.*) were perhaps the most nomadic and aggressive of the Apache west of the Rio Grande, raiding into northern Mexico, Arizona, and New Mexico from their strongholds in the Dragoon Mountains. The Western Apache appear to have been more settled than their Eastern relatives, with considerably more emphasis on farming, though they did raid, frequently with various Yuman tribes.

Although the Apache wars were among the fiercest fought on the frontier, the Apache had attempted to be friends of the Spanish, the Mexicans, and, later, the Americans. As early as the 17th century, however, Apache were raiding Spanish missions, and the Apache may have been partial instigators of the Pueblo Revolt of 1680 (see Pueblo Indians). In 1858 a meeting between Americans and Chiricahua Apache took place at Apache Pass in the Dragoon Mountains, resulting in a peace that lasted until 1861, when Cochise went on the warpath. This marked the beginning of the Apache and Navajo wars, a quarter-century confrontation between U.S. military forces and the Indians of the Southwest.

Despite their adept use of swift horses and their knowledge of the terrain, the Indians were outmatched by the superior arms of the federal troops. The Navajo surrendered in 1865 and agreed to settle on a reservation in New Mexico. The Apache ostensibly followed suit in 1871–73, but large numbers of warriors refused to yield their nomadic ways and to accept permanent confinement. Thus, intermittent raids continued to be led by such Apache leaders as Geronimo and Victorio, evoking federal action once more.

The last of the Apache wars ended in 1886 with the surrender of Geronimo and his few remaining followers. The Chiricahua tribe was evacuated from the West and held as prisoners of war successively in Florida, in Alabama, and at Ft. Sill, Okla., for a total of 27 years. In 1913 the members of the tribe were allowed either to take allotments of land in Oklahoma or to live in New Mexico on the Mescalero Reservation. About one-third chose the former and two-thirds the latter.

The Apache population totalled about 11,000 in the late 20th century. The Western Apache live on the Fort Apache and San Carlos reservations in east central Arizona.

The Chiricahua (except those still living near Apache, Okla.), the Mescalero, and the Lipan live on the Mescalero Reservation, which is located in southern New Mexico. The Jicarilla have a reservation situated in north central New Mexico.

Apadāna (Pāli: "Stories"), collection of legends about Buddhist saints, one of the latest books in the latest section (the *Khuddaka Nikāya*) of the *Sutta Piṭaka* ("Basket of Discourse") of the Pāli canon. This work, which is entirely in verse, presents stories about 547 monks and 40 nuns. For each personage there are tales about one or more previous lives as well as about his or her present existence, all of the tales presented as the words of the Buddha. The deeds these stories commend are meritorious acts of formal piety and charitable service. The Sanskrit cognate of the term is *Avadāna* (*q.v.*).

Apaiang (Kiribati): see Abaiang Atoll.

Apalachee, extinct tribe of North American Indians who spoke a Muskogean language and inhabited the area in northwestern Florida between the Aucilla and Apalachicola rivers above Apalachee Bay. They became known in the 16th century when the Spanish explorers Pánfilo de Narváez (in 1528) and Hernando de Soto (in 1539) led expeditions to Apalachee territory. The tribe was divided into clans that traced descent through the maternal line; chieftainship and office were hereditary, probably in the lineage within the clan.

An agricultural people who cultivated corn (maize), squash, and orange groves, the Apalachee were also noted warriors. They were ultimately subdued about 1600 and missionized by Spanish Franciscans. They continued to prosper (in 1655, 6,000–8,000 Apalachee occupied eight towns, each with a Franciscan mission) until early in the 18th century when Creek (*q.v.*) tribes to the north, incited by the British, began a series of raids on Apalachee settlements. These attacks culminated in 1703 when an army made up of a few hundred Englishmen and several thousand Creek warriors defeated the combined Spanish and Apalachee. The tribe was almost totally destroyed, and 1,400 Apalachee were removed to Carolina where some of them merged with the Creek. The remnants of the Florida tribe sought the protection of the French at Mobile and in Louisiana.

Apalachee Bay, arm of the Gulf of Mexico indenting northwestern Florida, U.S., 25 mi (40 km) south of Tallahassee. It receives the Ochlockonee, St. Mark, and Aucilla rivers, and its marshy coast forms St. Marks National Wildlife Refuge. In 1528, five boats were built in the bay by Pánfilo de Narváez, a Spanish officer who had decided to abandon his search for wealth in Florida and to set out for Mexico. The bay was named after the Apalachee Indian tribe.

Apalachicola, city, seat (1832) of Franklin county, northwestern Florida, U.S., on the Apalachicola Bay (bridged) at the mouth of Apalachicola River, on the Atlantic Intra-coastal Waterway, 65 mi (105 km) southwest of Tallahassee.

Founded about 1820 as West Point (renamed Apalachicola, Hitchiti Indian for "people on the other side," in 1831), it was an important cotton shipping port from 1830 until the U.S. Civil War blockade ended this activity. In the 1840s John W. Gorrie of Apalachicola invented a refrigerant apparatus to cool the rooms of yellow-fever patients (commemorated by a state historic memorial). An important fishing (oysters, shrimp) centre, the city also exports lumber and naval stores and has fish canneries. Old Trinity Church (1839), a notable landmark with Ionic columns, was shipped in wooden sections from New York. Nearby are St. George Island (bridged) and

Apalachicola National Forest. Inc. town, 1827; city, 1838. Pop. (1990) 2,602.

Apamama (Kiribati): see Abemama Atoll.

Apamea Cibotus, also called **APAMEA AD MAEANDRUM**, Apamea also spelled **APAMEIA**, city in Hellenistic Phrygia, partly covered by the modern town of Dinar, Tur. Founded by Antiochus I Soter in the 3rd century BC, it superseded the ancient Celaenae and placed it in a commanding position on the great east-west trade route of the Seleucid Empire. In the 2nd century BC Apamea passed to Roman rule and became a great centre for Italian and Jewish traders. Disorganization in the 3rd century AD and the diversion of trade to Constantinople led to its decline. It was captured by the Turks in 1070 and finally destroyed by an earthquake.

Apanás, Lake, Spanish **LAGO DE APANÁS**, reservoir in northern Nicaragua. Formed by damming the Río Tuma just north of Jinotega city, Lake Apanás has an area of 20 square miles (51 square km). It supplies the Asturias hydroelectric station, largest in the country and the focus of a power grid serving much of the more densely settled Pacific zone of Nicaragua.

apapane (*Himatione sanguinea*), Hawaiian songbird, common on larger islands, a nectar-feeding member of the Hawaiian honeycreeper family, Drepanididae (order Passeriformes). About 13 centimetres (5 inches) long, it is red, except for its dark wings and tail and its white vent. Its bill is fairly short and slightly

Apapane (*Himatione sanguinea*)

Drawing by John P. O'Neill

curved. The apapane lives chiefly in upland forests and is especially fond of ohia flowers.

Apapocuva, also called **NANDEVA**, a Guarani-speaking South American Indian people living in small, scattered villages throughout the Mato Grosso, Paraná, and São Paulo states of southeastern Brazil. In the second half of the 20th century, the Apapocuva probably numbered fewer than 500 individuals.

Traditionally, the Apapocuva were swidden agriculturalists who supplemented their crops of corn (maize), bitter and sweet cassava, beans, tubers, and other vegetables with gathered fruits and other forest products. The nominal leader of each village was usually a successful shaman who advised his group according to the revelations of his dreams. In 1879, an entire village followed its shaman in an eastward trek, in search of the Land-Without-Evil, which was believed to be somewhere over the Atlantic Ocean. In 1910, another Apapocuva group attempted to reach the Land-Without-Evil by dancing feverishly for days, in the hope of becoming light enough to

fly over the Atlantic Ocean. The present wide dispersal of Apapocuva over southeastern Brazil reflects their many and far-flung religious migrations of the past 100 years.

Aparanta (India): see Konkan.

Aparni (Parthian tribe): see Parni.

Aparri, town, northeastern Luzon, Philippines. It lies along the Babuyan Channel of the Philippine Sea, near the mouth of the Cagayan River. Aparri is the interisland port for much of northeastern Luzon. Anti-Spanish insurgents landed there in 1898 under Colonel Daniel Tirona, and civil government was restored in 1901 under the United States. The town's principal exports are rice, corn (maize), copra, logs, and fish products. Fishing, cattle raising, and the manufacture of fish paste are the main local industries. The population is mainly Christian Ilocanos and Ibanags. Pop. (1990) 51,635.

apartheid (Afrikaans: "apartness"), policy that governed relations between South Africa's white minority and nonwhite majority and sanctioned racial segregation and political and economic discrimination against nonwhites. The implementation of apartheid, often called "separate development" since the 1960s, was made possible through the Population Registration Act of 1950, which classified all South Africans as either Bantu (all black Africans), Coloured (those of mixed race), or white. A fourth category—Asian (Indian and Pakistani)—was later added.

Racial segregation, sanctioned by law, was widely practiced in South Africa before 1948, but the National Party, which gained office that year, extended the policy and gave it the name apartheid. The Group Areas Act of 1950 established residential and business sections in urban areas for each race, and members of other races were barred from living, operating businesses, or owning land in them. In practice this act and two others (1954, 1955), which became known collectively as the Land Acts, completed a process that had begun with similar Land Acts adopted in 1913 and 1936; the end result was to set aside more than 80 percent of South Africa's land for the white minority. To help enforce the segregation of the races and prevent blacks from encroaching on white areas, the government strengthened the existing "pass" laws, which required nonwhites to carry documents authorizing their presence in restricted areas. Other laws forbade most social contacts between the races, authorized segregated public facilities, established separate educational standards, restricted each race to certain types of jobs, curtailed nonwhite labour unions, and denied nonwhite participation (through white representatives) in the national government.

Under the Bantu Authorities Act of 1951 the government reestablished tribal organizations for black Africans, and the Promotion of Bantu Self-Government Act of 1959 created 10 African homelands. The Bantu Homelands Citizenship Act of 1970 made every black South African, irrespective of actual residence, a citizen of one of the homelands, thereby excluding blacks from the South African body politic. Four of the homelands were granted independence as republics, and the remaining, called Black States, had varying degrees of self-government; but all remained dependent, both politically and economically, on South Africa. The dependence of the South African economy on nonwhite labour, though, made it difficult for the government to carry out this policy of separate development.

Although the government had the power to suppress virtually all criticism of its policies, there was always some opposition to apartheid within South Africa. Black African groups, with the support of some whites, held demonstrations and strikes, and there were many instances of violent protest and of sabotage.

An attempt to enforce Afrikaans language requirements for black African students led to the Soweto riots in 1976. Some white politicians called for the relaxation of minor restrictions, referred to as "petty apartheid," or for the establishment of racial equality.

Apartheid also received international censure. South Africa was forced to withdraw from the Commonwealth in 1961 when it became apparent that other member countries would not accept its racial policies. In 1985 both the United Kingdom and the United States imposed selective economic sanctions on South Africa. In response to these and other pressures, the South African government abolished the "pass" laws in 1986, although blacks were still prohibited from living in designated white areas and the police were granted broad emergency powers.

In a more fundamental shift of policy, however, the government of South African president F.W. de Klerk in 1990–91 repealed most of the social legislation that provided the legal basis for apartheid, including the Population Registration Act. Systematic racial segregation remained deeply entrenched in South African society, though, and continued on a de facto basis. In 1993 a new constitution enfranchised blacks and other racial groups, and all-race national elections in 1994 produced a coalition government with a black majority. These developments marked the end of legislated apartheid, though not of its entrenched social and economic effects.

apartment house, also called APARTMENT BLOCK, or BLOCK OF FLATS, building containing more than one dwelling unit, most of which are designed for domestic use, but sometimes including shops and other nonresidential features.

Unité d'Habitation, apartment house, Marseille, designed by Le Corbusier, 1946–52

© Wayne Andrews/Esto

Apartment buildings have existed for centuries. In the great cities of the Roman Empire, because of urban congestion, the individual house, or domus, had given way in early imperial times to the communal dwelling, or insula (*q.v.*), except for the residences of the very wealthy. Four stories were common, and six-, seven-, or eight-story buildings were occasionally constructed. Another type of apartment existed in Europe in the Middle Ages, consisting of a great house or mansion, part of which was subdivided into smaller sets of rooms in order to house the servants and other retainers of an important person. In contrast to these "apartments," which were simply personal suites within great houses, the apartment house as it is known today first appeared in Paris and other large European cities in the 18th century, when tall blocks of flats for middle-class tenants began appearing. In the typical Parisian apartment building, the size of the apartments (and the financial means

of the tenants) decreased with each successive story in a four- or five-story building.

By the mid-19th century, large numbers of inexpensive apartment houses were under construction to house swelling numbers of industrial labourers in cities and towns across Europe and in the United States. These buildings were often incredibly shabby, poorly designed, unsanitary, and cramped. The typical New York City apartment, or tenement, a type first constructed in the 1830s, consisted of apartments popularly known as railroad flats because the narrow rooms were arranged end-to-end in a row like boxcars. Indeed, few low-cost apartment buildings erected in Europe or America before 1918 were designed for either comfort or style. In many European cities, however, particularly in Paris and Vienna, the second half of the 19th century witnessed great progress in the design of apartments for the upper-middle class and the rich.

The modern large apartment building emerged in the early 20th century with the incorporation of elevators, central heating, and other conveniences that could be shared in common by a building's tenants. Apartments for the well-to-do began to offer other amenities such as leisure facilities, delivery and laundry services, and communal dining rooms and gardens. The multistory apartment house continued to grow in importance as crowding and rising land values in cities made one-family homes less and less practicable in parts of many cities. Much government-subsidized, or public, housing has taken the form of apartment buildings, particularly for the urban elderly and working classes or those living in poverty. Apartment-block towers also were erected in large numbers in the Soviet Union and other countries where housing construction was the responsibility of the state.

Since World War II the demand for apartment housing has continued to grow as a result of continued urbanization. The mid- or high-rise apartment complex has become a fixture of the skylines of most of the world's cities, and the two- or three-story "walk-up" apartment also remains popular in somewhat less built-up urban areas.

The most common form of occupancy of apartment houses has been on a rental basis. However, multiple ownership of units on a single site has become much more common in the 20th century. Such ownership can take the form of cooperatives or condominiums. In a cooperative, all the occupants of a building own the structure in common; cooperative housing is much more common in parts of Europe than it is in the United States. A condominium denotes the individual ownership of one dwelling unit in an apartment house or other multidwelling building. The increasing popularity of condominiums in the United States and elsewhere is based largely on the fact that, unlike members of a cooperative, condominium owners are not financially interdependent and can mortgage their property.

apathy, in Stoic philosophy, condition of being totally free from the *pathē*, which roughly are the emotions and passions, notably pain, fear, desire, and pleasure. Although remote origins of the doctrine can probably be found in the Cynics (second half of the 4th century BC), it was Zeno of Citium (4th–3rd century BC) who explicitly taught that the *pathē* were to be extirpated entirely.

Attacks on the Stoics suggesting that they were insensitive to the human condition invoked rejoinders from the later Stoics, some of whom compromised by distinguishing between good and evil *pathē*. Early Stoics, however, rejected the *pathē* altogether, breaking with the Aristotelians, who sought a mean between them, and with the Epicureans, who

proclaimed pleasure, rightly chosen, to be the only criterion by which to judge an action. One of the greatest of the Middle Stoics (2nd–1st century BC), however, Panaetius, rejected the idea of apathy altogether and reintroduced the Aristotelian doctrine of the golden mean (or of virtue as a mean between two extremes) and argued (as did Seneca, the 1st-century-AD Roman Stoic philosopher) that some of the goods of this world might be worth pursuing for their own sake.

apatite, any member of a series of phosphate minerals, the world's major source of phosphorus, found as variously coloured, glassy crystals, masses, or nodules. If not for its softness (Mohs hardness 5, compared with the 7 to 9 of most gems), apatite would be a popular gemstone: much of the material found is clear, but it is fragile and difficult to cut and polish. Asparagus stone is a clear, asparagus-green gem variety of apatite; moroxite, a clear blue.

The series includes fluorapatite (the most important mineral commercially), chlorapatite, hydroxylapatite, and carbonate-apatite. These minerals are all calcium phosphates, differing from one another chemically only in that fluorapatite contains fluorine; chlorapatite, chlorine; hydroxylapatite, a hydroxyl (OH) group; and carbonate-apatite, a carbonate (CO₃) group. The fluorine, chlorine, hydroxyl, and carbonate substitute for one another, so that in nature most apatite is a mixture of several of the compounds. Chlorapatite and carbonate-apatite are comparatively rare. For properties, see phosphate mineral (table).

Apatite is a member of a group of structurally related minerals having compositions symbolized $A_5(BO_4)_3X$, in which *A* is a metal, commonly calcium or lead; *B* is phosphorus, vanadium, or arsenic; and *X* is chlorine, fluorine, or hydroxyl. The group contains three series: the apatite series, the pyromorphite series, and the svabite series (intermediate between the other two).

Apatosaurus, formerly BRONTOSAURUS, genus of giant herbivorous dinosaurs, one of the largest land animals of all time, found in Late Jurassic deposits of North America and Europe (163 to 144 million years ago). *Apatosaurus* weighed as much as 30 tons and was as much as 21 m (70 feet) long, including its long neck and tail. It had four massive and pillarlike legs.

The size, shape, and features of the *Apatosaurus* head were disputed for more than a century after its remains were first uncovered, certainty clouded in part by incomplete fossil finds and by a suspected mix-up of fossils during shipment from an excavation site. The head was represented in models as a massive, snub-nosed skull with spoonlike teeth until 1978, when scientists rejected that represen-

Apatosaurus drawn with (top) blunt skull incorrectly assigned c. 1879 and (bottom) slender skull assigned in 1978

By courtesy of the Carnegie Museum of Natural History, Pittsburgh

tation in favour of a slender, elongated skull containing long, peglike teeth.

Much discussion has centred on whether *Apatosaurus* and related forms were able to support their great bulk on the land or whether they were forced to adopt aquatic habits. It now seems likely that *Apatosaurus* was primarily a land animal. It had no skeletal features indicative of an aquatic environment, and experiments suggest that its bones could easily have supported its great weight. Even the massive *Brachiosaurus*, which weighed about 80 tons, was probably more often on land than in the water.

Apaturia, Greek religious festival that was held annually in nearly all the Ionian towns. At Athens it took place in the month of Pyanopsion (October–November) and lasted three days, on which occasion the various phratries (clans) of Attica met to discuss their affairs. The name probably means the festival of “common relationship.” The most important day was probably the third, Koureotis, when children born since the last festival were presented by their fathers or guardians; after an oath had been taken as to their legitimacy, their names were inscribed in the register.

Apatzingán, in full APATZINGÁN DE LA CONSTITUCIÓN, city, west-central Michoacán *estado* (“state”), west-central Mexico. It lies along the Apatzingán (Acahuato) River, 176 miles (283 km) southwest of Morelia, the state capital. Its name commemorates the signing there, in 1814, of the Constitution of Apatzingán by the congress called by the revolutionary leader José María Morelos to declare Mexican independence. The city links the sparsely inhabited southern and densely populated central portions of Michoacán. Although the climate is hot and semiarid, the agricultural and pastoral hinterland is rich. Corn (maize), beans, sesame, rice, cotton, and fruits are the principal crops. Pop. (2000 est.) city, 92,000.

apavarga (Indian philosophy): see moksha.

Ape (pseudonym): see Pellegrini, Carlo.

ape, any of the tailless, manlike primates of the families Hylobatidae (gibbon and siamang) and Pongidae (chimpanzee, bonobo, orangutan, and gorilla), found in the tropical forests of western and central Africa and Southeast Asia. Apes are distinguished from monkeys by the complete absence of a tail, by the presence of an appendix, and by their more complex brains. Apes typically move about by swinging, or brachiation; they also display a tendency to stand erect and, occasionally, to move bipedally, especially when carrying an object. The gibbon, siamang, and orangutan (*qq.v.*) are arboreal, while the gorilla, chimpanzee, and bonobo (*qq.v.*) spend some or much of their time on the ground. Pongids travel on the ground by quadrupedal knuckle-walking, in which the long fingers of the forelimbs are folded under to provide support for the body. Fruits and other vegetal materials are the chief foods, though small invertebrates and even small vertebrates are eaten occasionally. Most apes lodge at night in trees, all except gibbons building sleeping nests for the purpose. Group size ranges from the virtually solitary orangutan to the sociable chimpanzees and bonobos, who may live in bands of up to 100 members. Destruction of their forest habitats and hunting by humans have resulted in severe population declines among the apes, all species of which have been classified as endangered by the U.S. Department of the Interior.

The evolutionary history of the apes includes numerous extinct forms, many of which are known only from fragmentary remains. The earliest known fossils date from the Oligocene Epoch (beginning about 36.6 million years ago) in Egypt and include such forms as *Aeolopithecus*, a possible ancestor of the gibbon,

and *Aegyptopithecus*, a possible ancestor of the great apes. Later deposits have yielded such fossils as the gibbonlike *Pliopithecus* and *Linnopithecus* and the great-ape-like *Dryopithecus* (including *Proconsul*).

Apes are intelligent animals and are more closely related to humans than any other living primates. The gorilla, chimpanzee, bonobo, and orangutan are called great apes in recognition of their comparatively large size and manlike features, while the gibbon and siamang are called lesser apes. The term ape is also used in a less-restricted sense to refer to certain large tailless monkeys, such as the Celebes black ape (*q.v.*).

Apeldoorn, *gemeente* (commune), Gelderland *provincie*, east-central Netherlands. It lies east of the sandy and wooded Veluwe Hills, on the edge of the Soeren (Suren) Forest. Noted for its many gardens, Apeldoorn is a residential and industrial town that manufactures paper products, pharmaceuticals, chemicals, and refrigeration machinery. There are many sanitariums in the district, and the Hoge Veluwe National Park is 8 miles (13 km) southwest. On the town's northern outskirts is Het Loo, a royal palace built for William III in 1686 around a smaller castle. Apeldoorn is a junction for roads and railways and is connected by canal to Zwolle. Pop. (1999 est.) 152,860.

apella, ancient Spartan assembly, corresponding to the *ekklesia* of other Greek states. Its monthly meetings, probably restricted to full citizens over 30, were presided over at first by the kings, later by ephors (magistrates). Not empowered to initiate proposals, the body considered subjects forwarded by the ephors or *gerousia* (council of elders). Only kings, elders, ephors, and perhaps other magistrates could debate, and voting was conducted by shouts. Foreign policy, including treaties and issues of peace and war, as well as questions of succession to the throne, were within the province of the *apella*. It also appointed military commanders, elected the elders and ephors, and voted on proposed changes in the laws.

Apelles (fl. 4th century BC), early Hellenistic Greek painter whose work was held in such high esteem by ancient writers on art that he continues to be regarded, even though none of his work survives, as the greatest painter of antiquity.

Almost as little is known of Apelles' life as of his art. He was of Ionian origin but became a student at the celebrated Dorian school of Sicyon in southern Greece, where he worked under the painter Pamphilus. His works are said to have combined Dorian thoroughness with Ionic grace.

He became the recognized court painter of Philip II of Macedonia and his son Alexander III the Great. His picture of Alexander holding a thunderbolt ranked among his outstanding works. Other notable works of Apelles include portraits and a great allegorical picture representing Calumny and a painting representing Aphrodite rising out of the sea. Of these works no copies survive; descriptions of his works, however, inspired later artists to emulate them, especially during the Italian Renaissance.

It is said that he attached great value to the drawing of outlines, practicing every day. The tale is well known of his visit to Protogenes and the rivalry of the two masters as to which could draw the finest and steadiest line. He probably used only a small variety of colours and avoided elaborate perspective. Simplicity of design, beauty of line, and charm of expression were supposedly his chief merits.

Apelles was also noted for improvements in technique. He used a dark glaze, called *atramentum*, that served both to preserve his paintings and to soften their colour. There is

little doubt that he was one of the boldest and most progressive of artists of his time.

Apellicon OF TFOOS (d. c. 84 BC), a wealthy Greek book collector, who became an Athenian citizen. He had bought from the descendants of Neleus of Scepis in the Troad the libraries of Aristotle and Theophrastus, which were in a damaged condition but might have contained the only copies of the Aristotelian treatises to survive. Apellicon is said to have published them with corrections and supplements. After his death, when Sulla captured Athens, the books were carried off to Rome where eventually they formed the basis of a famous edition by Andronicus of Rhodes.

Apennine Range, also called THE APENNINES, Italian APENNINO, arc of mountains forming the backbone of peninsular Italy that have had considerable influence on the human geography of the nation.

A brief treatment of the Apennine Range follows. For full treatment, see MACROPAEDIA: Europe.

The Apennines stretch from the Cadibona Pass, close to the maritime Alps in the northwest, as far as the Egadi Islands to the west of Sicily, although the Apennines proper extend only to Calabria, at the southern tip of Italy. Their total length is approximately 870 miles (1,400 km), and their width ranges from 25 to 125 miles (40 to 200 km). Mount Corno at 9,554 feet (2,912 m) is the highest point. The range follows a northwest to southeast orientation as far as Calabria; the regional trend then changes direction in Sicily, first toward the south and then westward.

The Apennines are among the younger ranges of the Alpine system and are related geologically to the coastal range of the Atlas Mountains of North Africa. Geographically, the Apennines differ strikingly from the Alps. They have lower elevations and lack glaciers, and the maritime influence on the valleys and exposed slopes is much greater. The geologic youth of the Apennines and a great variety of rock types are responsible for the rugged appearance of the range. Rock types include sandstones, marls, greenstones, and clays. Earthquakes are frequent, especially within the central and southern Apennines and Sicily, and are caused by structural settling of the young mountain chain, by movements along the abundant faults, and by volcanic activity.

Apepi (Egyptian god): see Apopis.

Apert's syndrome (congenital malformation): see acrocephalosyndactyly.

aperture, in optics, the maximum diameter of a light beam that can pass through an optical system. The size of an aperture is limited by the size of the mount holding the optical component, or the size of the diaphragm placed in the bundle of light rays. The hole in the mount or diaphragm that limits the size of the aperture is called an aperture stop. Thus, an aperture stop determines the amount of light that traverses an optical system and hence determines the image illumination.

Closely related to the aperture stop is its image, called the entrance pupil of the optical system. The angle that the diameter of the entrance pupil subtends at an object point is called the angular aperture, which can be taken as a measure of the light-gathering power of the instrument. See also pupil; relative aperture.

Aphanomyces, genus of parasitic fungi (division Mycota) of the order Saprolegniales (class Oomycetes) that forms two successive asexual, motile spores (zoospores). The first one is produced in a spore sac (sporangium) but soon forms a cyst from which the second zoospore arises. The latter, on contact, infects a susceptible host plant. A thick-walled structure (oospore) forms after sexual union. *A. euteiches* causes root rot of English pea.

aphasia, also called DYSPLASIA, defect in the expression and comprehension of language caused by damage to the brain. Aphasia can be caused by injury, tumour, stroke, or infection.

The areas of the brain involved with language are centred around the Sylvian fissure, the cleft separating the temporal, frontal, and parietal lobes. In right-handed people and a majority of those who are left-handed, the language areas are almost always in the left cerebral hemisphere. In a small number of left-handed people, they are occasionally located in the right cerebral hemisphere. Broca's area, at the foot of the frontal lobe, is responsible for expression of language; Wernicke's area, at the upper part of the temporal lobe, is responsible for language comprehension.

Damage to the frontal lobe may result in Broca's aphasia. Individuals with this form of aphasia are able to comprehend speech but have great difficulty expressing their thoughts. People with Broca's aphasia speak in short phrases that include only nouns and verbs (telegraphic speech). Individuals with Wernicke's aphasia, which results from damage to the temporal lobe, speak in long, garbled sentences (word salad) and have poor speech comprehension. Global aphasia, with symptoms of both Broca's and Wernicke's aphasia, results from extensive brain damage.

Speech therapy may be useful to treat aphasia. In some instances, improvement may be due to assumption of some language functions by other areas of the brain; recovery is usually incomplete, however. (R.Jo.)

Aphik, Canaanite royal city near the present-day Israeli city of Petah Tiqwa (q.v.). Conquered by Joshua (Joshua 12:18), it became a Philistine stronghold in the period of the Judges. Its importance is attested by its mention among the cities conquered by the pharaohs Thutmose III and Amenhotep II. Much later, in the 1st century BC, the city of Antipatris was built on the site by King Herod the Great.

aphid, also called PLANT LOUSE, GREENFLY, or ANT COW, any of several species of sap-sucking, soft-bodied insects (order Homoptera) about the size of a pinhead, with tubelike projections (cornicles) on the abdomen. It is a serious plant pest. Aphids not only stunt plant growth, produce plant galls, and transmit plant virus diseases but also deform leaves, buds, and flowers. The life cycle of the aphid is complicated. Wingless females, called stem mothers, produce living young without fertilization (i.e. by parthenogenesis) throughout the summer. Eventually the plant containing the stem mother and her offspring becomes overcrowded; when this occurs, some aphids develop two pairs of large membranous wings and seek new plants. In late summer, both males and females are produced; after they mate, the female lays eggs that survive the winter. In warm climates there may be no egg stage. The white, woolly-ball appearance of

Rose aphids (*Macrosiphum rosae*)

Anthony R. ...

many aphids is the result of wax-gland secretion. Aphids are controlled—e.g. ladybird beetles, aphid lions, and lacewings.

Ants may take care of aphids, protecting them from weather and natural enemies and transferring them from wilted to healthy plants. In this way they ensure their source of honeydew, a sweet excretory product of aphids. Ants obtain honeydew by stroking, or "milking," the aphids. Common types of aphids include the following:

The apple aphid (*Aphis pomi*) is yellow-green with dark head and legs. It overwinters as a black egg on its only host, the apple tree. It produces honeydew that supports growth of a sooty mold.

The cabbage aphid (*Brevicoryne brassicae*) is small and gray-green with a powdery, waxy covering. It is found in clusters on the underside of leaves of cabbage, cauliflower, Brussels sprouts, and radishes. It overwinters as black eggs in northern regions but has no sexual stage in southern regions. It is controlled by dusts or sprays.

The cooley spruce gall aphid (*Chermes cooleyi*) causes formation of conelike galls about 7 cm (3 inches) long on the tips of spruce twigs. In midsummer when the galls open, adults migrate to Douglas firs to lay eggs; the life cycle may proceed on either spruce or Douglas fir. Control is by spraying with insecticide, removing galls before aphids emerge, and planting spruce and Douglas fir apart from each other.

The corn root aphid (*Anuraphis maidi-radicis*) is a serious pest dependent on the cornfield ant; the ants store aphid eggs in their nests during the winter, and in spring the aphids are carried by the ants to weed roots and then transferred to corn roots. The aphid stops growth of corn and causes plants to turn yellow and wilt; it also infests other plants.

The eastern spruce gall aphid (*Chermes abietis*) produces pineapple-shaped galls 1 to 2.5 cm long composed of many cells, each containing about 12 aphid nymphs; galls open in midsummer, releasing mature aphids that infect the same or another spruce. New galls are green with red or purple lines; old galls are brown. Infested branches often die, but individual trees vary in susceptibility. The best control is by poisonous spray.

The greenbug (*Toxoptera graminum*) is one of the most destructive pests of wheat, oats, and other small grains. It appears as patches of yellow on the plant and may wipe out an entire field. Pale green adults have a dark green stripe down the back; each female produces between 50 and 60 young per generation, and there are 20 generations annually. It is controlled by parasites and chemical sprays.

The green peach aphid (*Myzus persicae*), also called the spinach aphid, is pale yellow-green with three dark lines on the back. The life cycle involves two hosts; the female reproduces parthenogenetically during summer and produces sexual males and females in autumn. It is a serious pest, transmitting many plant mosaics.

The melon, or cotton, aphid (*Aphis gossypii*) is green to black. In warm climates live young are produced all year, while in cooler areas there is an egg stage. Among the dozens of possible hosts are melon, cotton, and cucumber. It is usually controlled by parasites and natural predators.

The pea aphid (*Macrosiphum pisi*) is pale green; it kills pea plants and carries yellow bean mosaic. It overwinters on clover and alfalfa, migrating to peas in spring. Each female produces 50 to 100 young in each of 7 to 20 generations a year. It is controlled by sprays and weather conditions.

The potato aphid (*Macrosiphum euphorbiae*) begins as black eggs on rose plants, which hatch into pink and green young that feed on rosebuds and leaves. In early spring they migrate to the summer host (potato plant). One generation occurs every two to three weeks. It is the carrier of tomato and potato mosaic virus diseases and kills vines and blossoms.

The rose aphid (*Macrosiphum rosae*) is large and green with black appendages and pink markings. It is common on its only host, the cultivated rose. Natural predators are ladybird larvae and aphid lions.

The rosy apple aphid (*Anuraphis roseus*) deforms fruit, producing "aphis apples." It causes leaves to curl about it, forming a protection from insecticide sprays. The life cycle involves an alternate host, plantain; the aphid returns to the apple tree to deposit eggs in the fall. It also attacks pear, hawthorn, and mountain ash. It is controlled by sprays and by natural enemies, chiefly syrphid flies, lady beetles, lacewings, and parasitic wasps.

The woolly apple aphid (*Eriosoma lanigerum*) lives on roots and may stunt or kill apple trees. White cottony masses enclose the young aphids. It is controlled by parasites.

See also grape phylloxera.

aphorism, a concise expression of doctrine or principle or any generally accepted truth conveyed in a pithy, memorable statement. Aphorisms have been especially used in dealing with subjects that were late in developing their own principles or methodology—for example, art, agriculture, medicine, jurisprudence, and politics. The term was first used in the *Aphorisms* of Hippocrates, a long series of propositions concerning the symptoms and diagnosis of disease and the art of healing and medicine. The first aphorism, which serves as a kind of introduction to the book, runs as follows: "Life is short, Art long, Occasion sudden and dangerous, Experience deceitful, and Judgment difficult. Neither is it sufficient that the physician be ready to act what is necessary to be done by him, but the sick, and the attendants and all outward necessities must be lightly prepared and fitted for the business."

A well-known medieval collection of aphorisms is that formulated in about 1066 in Latin verse by the celebrated doctor Joannes de Meditano, giving the precepts of the medical school of Salerno. Another collection of aphorisms, also medical and also in Latin, is that of the Dutchman Hermann Boerhaave, published at Leiden in the year 1709; it gives a terse summary of the medical knowledge prevailing at the time and is of great interest to the student of the history of medicine.

The term was gradually applied to the principles of other fields and finally to any statement generally accepted as true, so that it is now roughly synonymous with maxim.

Aphraates, SYRIAC AFRAHAT (fl. 4th century), Syrian ascetic and the earliest-known Christian writer of the Syriac church in Persia.

Aphraates became a convert to Christianity during the reign of the anti-Christian Persian king Shāpūr II (309–379), after which he led a monastic life, possibly at the Monastery of St. Matthew near Mosul, Iraq. Later he may have become a bishop when he assumed the name James. Termed "the Persian Sage," Aphraates between the years 336 and 345 composed Syriac biblical commentaries (23 of which have been preserved) for his monastic colleagues. They are inaccurately known as his "Homilies," and they survey the Christian faith predominantly in theological, ascetical, and disciplinary matters, at times marked by a sharp polemical nature. Nine treatises against the Jews, who were numerous in Mesopotamia and had established outstanding schools, are particularly acrimonious; they treat of Easter,

circumcision, dietary laws, the supplanting of Israel by Gentiles as the new chosen people, and Jesus' divine sonship.

Aphraates' writings are distinguished by their primitive biblical-theological tradition, as yet unaffected by the doctrinal controversies and linguistic complexity growing out of the Trinitarian (nature of God) and Christological (nature of Christ) controversies prior and subsequent to the Council of Nicaea in 325. Insulated from the intellectual currents traversing the Greco-Roman ecclesiastical world, the "Homilies" manifest a teaching indigenous to early Assyrian Judeo-Christianity.

Aphrem SYRUS, SAINT: see Ephraem Syrus, Saint.

aphrodisiac, any of various forms of stimulation thought to arouse sexual excitement. Aphrodisiacs may be classified in two principal groups: (1) psychophysiological (visual, tactile, olfactory, aural) and (2) internal (stemming from food, alcoholic drinks, drugs, love potions, medical preparations).

Despite long-standing literary and popular interest in internal aphrodisiacs, almost no scientific studies of them have been made. Scientific research is limited to occasional tests of drugs or hormones for the cure of male impotence. Most writings on the subject are little more than unscientific compilations of traditional or folkloric material. Of the various foods to which aphrodisiac powers are traditionally attributed, fish, vegetables, and spices have been the most popular throughout history. In none of these foods, however, have any chemical agents been identified that could effect a direct physiological reaction upon the genitourinary tract, and it must be concluded that the reputation of various supposedly erotic foods is based not upon fact but upon folklore.

It has been suggested that man's universal attribution of libidinous effects to certain foods originated in the ancient belief in the therapeutic efficacy of signatures: if an object resembled the genitalia, it possessed, so it was reasoned, sexual powers. Thus the legendary aphrodisiac powers of ginseng root and powdered rhinoceros horn.

With the exception of certain drugs such as alcohol or marijuana, which may lead to sexual excitation through disinhibition, modern medical science recognizes a very limited number of aphrodisiacs. These are, principally, cantharides and yohimbine, both of which stimulate sexual arousal by irritating the urinary tract when excreted. Cantharides, or cantharidin, consists of the broken dried remains of the blister beetle (*q.v.*) *Lytta vesicatoria*. It has been a traditional sexual stimulant fed to male livestock to facilitate breeding. In humans the substance produces skin blisters on contact, and attempts to ingest it as an aphrodisiac are considered extremely hazardous. Yohimbine is a crystalline alkaloid substance derived from the bark of the yohimbé tree (*Corynanthe yohimbe*) found in central Africa, where it has been used for centuries to increase sexual powers. Although it has been promoted as an aphrodisiac, most investigators feel that any clinical change in sexual powers after its use is probably due to suggestion, because stimulatory effects are elicited only with toxic doses.

Aphrodisias, ancient city of the Caria region of southwestern Asia Minor (Anatolia, or modern Turkey), situated on a plateau south of the Maeander River (modern Menderes). Remains of an Ionic temple of Aphrodite and of a stadium and portions of a bathhouse have long been evident, but, beginning in 1961, excavations revealed such structures as a theatre, an odeon, a basilica, a market, houses and baths, a monumental gateway, and a cult centre for worship of the Roman emperor. Julius Caesar favoured the city, and the em-

peror Augustus granted it the high privileges of autonomy and tax-free status, declaring it "the one city from all of Asia that I have selected to be my own." In the Roman Empire, the city was famed for its sculptors and sculptures; rich quarries of excellent white and blue-gray marble lay about a mile east of the site. It also flourished owing to its site amid rich and well-watered agricultural land.

BIBLIOGRAPHY. Kenan T. Erim, *Aphrodisias: City of Venus Aphrodite* (1986).

Aphrodite, ancient Greek goddess of sexual love and beauty, identified by the Romans with Venus (*q.v.*). Because the Greek word *aphros* means "foam," the legend arose that Aphrodite was born from the white foam

Aphrodite and Eros, gilt bronze mirror with incised design, Greek, 4th century BC; in the Louvre, Paris Giraudon—Art Resource

produced by the severed genitals of Uranus (Heaven), after his son Cronus threw them into the sea. Aphrodite was, in fact, widely worshiped as a goddess of the sea and of seafaring; she was also honoured as a goddess of war, especially at Sparta, Thebes, Cyprus, and other places. Aphrodite was, however, primarily a goddess of love and fertility and even occasionally presided over marriage. Although prostitutes considered Aphrodite their patron, her public cult was generally solemn and even austere.

Many scholars believe Aphrodite's worship came to Greece from the East, and many of her characteristics must be considered Semitic. Although Homer called her "Cyprian" after the island chiefly famed for her worship, she was already Hellenized by the time of Homer, and, according to Homer, she was the daughter of Zeus and Dione, his consort at Dodona. In the *Odyssey*, Aphrodite was mismatched with Hephaestus, the lame smith god, and she consequently spent her time philandering with the handsome god of war, Ares (by whom she became the mother of Harmonia).

Of Aphrodite's mortal lovers, the most important were the Trojan shepherd Anchises, by whom she became the mother of Aeneas, and the handsome youth Adonis (in origin a Semitic nature deity and the consort of Ishtar-Astarte), who was killed by a boar while hunting and was lamented by women at the festival of Adonia. The cult of Adonis had underworld features, and Aphrodite was also connected with the dead at Delphi.

Aphrodite's main centres of worship were at Paphos and Amathus on Cyprus and on the island of Cythera, a Minoan colony, where her cult probably originated in prehistoric times. On the Greek mainland Corinth was the chief centre of her worship. Her close association with Eros, the Graces (Charites), and the Horae (Seasons) emphasized her role as a promoter of fertility. She was universally honoured as Genetrix, the creative element in the world. Her epithets Urania (Heavenly Dweller) and Pandemos (Of All the People) were incorrectly taken by the philosopher Plato to refer to intellectual and common love; rather, the title Urania was honorific and applied to certain

Oriental deities, while Pandemos referred to her standing within the city-state. Among her symbols were the dove, pomegranate, swan, and myrtle.

Early Greek art represented Aphrodite either as the Oriental nude-goddess type or as a standing or seated figure similar to all other goddesses. Aphrodite first attained individuality at the hands of the great 5th-century-BC Greek sculptors. Perhaps the most famous of all statues of Aphrodite was carved by Praxiteles for the Cnidians; it later became the model for such Hellenistic masterpieces as the Venus de Milo.

Aphthartodocetism (Greek *aphthartos*, "incorruptible"), a Christian heresy of the 6th century that carried Monophysitism ("Christ had but one nature and that divine") to a new extreme; it was proclaimed by Julian, bishop of Halicarnassus, who asserted that the body of Christ was divine and therefore naturally incorruptible and impassible; Christ, however, was free to will his sufferings and death voluntarily. Severus, patriarch of Antioch, himself a condemned Monophysite, vigorously challenged Julian on the ground that the doctrine of salvation was meaningless unless Christ's body was truly human. The Byzantine emperor Justinian I proclaimed the new heresy in an edict of 564 and would have imposed it on the Eastern church but for his death the following year.

Apia, town, port, and capital (since 1959) of Samoa. It is located on the northern coast of Upolu Island, in the South Pacific Ocean. The Apia Observatory, the legislative council chambers, and a broadcasting station are on the Mulinu Peninsula, a promontory dividing Apia Harbour from Vaiusu Bay. The 19th-century Scottish writer Robert Louis Stevenson spent the last year of his life in Apia, and his home, Vailima, is now the residence of the head of state. Stevenson is buried at Mount Vaea, which rises to 1,500 feet (460 metres) on the town's southern outskirts. The government holds title to the town land.

Vailima, former home of the Scottish writer Robert Louis Stevenson, in Apia, Samoa
Morton Beebe—Photo Researchers

During the colonial period a typhoon struck the island in March 1889, destroying six warships (three German, three U.S.) in the Apia roadstead; only the British ship *Calliope* escaped. U.S. Marines garrisoned in Apia during World War II built several roads and an airstrip. The town's commercial activities centre on the export of coconut products and fruits and the assembly of electric parts; food-stuffs such as taro and other root crops are shipped to American Samoa. Apia is also a centre for diversified manufacturing and tourism. Pop. (1999 est.) 38,000.

Apiaceae, also called UMBELLIFERAE, the parsley family, in the order Apiales, comprising between 300 and 400 genera of plants dis-

tributed throughout a wide variety of habitats, principally in the north temperate regions of the world. Most members are aromatic herbs with alternate, feather-divided leaves that are sheathed at the base. The flowers are often arranged in a conspicuous umbel (a flat-topped cluster of flowers). Each small individual flower is usually bisexual, with five sepals,

(Top) Masterwort (*Astrantia*) and (bottom) sea holly (*Eryngium maritimum*)

(Top) G.E. Hyde from the *Natura* History Photographic Agency; bottom Klaus Fiedler—Bruce Coleman Ltd.

five petals, and an enlarged disk at the base of the style. The fruits are ridged and are composed of two parts that split open at maturity.

Many species of the Apiaceae are poisonous, including poison hemlock (*Conium maculatum*), water hemlock (*Cicuta maculata*), and fool's parsley (*Aethusa cynapium*). Other species, however, are widely used vegetables, including parsley (*Petroselinum crispum*), carrot (*Daucus carota*), celery (*Apium graveolens*; see photograph), parsnip (*Pastinaca sativa*), and fennel (*Foeniculum vulgare*). Species used as herbs and spices include anise (*Pimpinella anisum*), dill (*Anethum graveolens*), coriander (*Coriandrum sativum*), caraway (*Carum carvi*), and cumin (*Cuminum cyminum*). Several species have long been used as herbal and folk remedies; e.g., gum ammoniac (*Dorema ammoniacum*) and goutweed (*Aegopodium podagraria*). Some species are grown for their ornamental value; e.g., masterwort (*Astrantia*), blue lace flower (*Trachymene caerulea*), and sea holly (*Eryngium maritimum*).

apicomplexan, also called SPOROZOAN, any protozoan of the (typically) spore-producing phylum Apicomplexa, which is called by some authorities Sporozoa. All apicomplexans are parasitic and lack contractile vacuoles and locomotor processes. Apicomplexans live within the body cavities or the cells of almost every kind of animal, including other apicomplexans. Some genera are pathogenic: *Plasmodium* causes malaria, and *Eimeria* and *Isospora* cause coccidiosis. Apicomplexans feed by ab-

sorbing either dissolved food ingested by the host (saprozoic nutrition) or the host's cytoplasm and body fluids. Respiration and excretion occur by simple diffusion through the cell membrane. In the life cycle, sexual and asexual generations may alternate. Sexual reproduction may immediately precede spore formation. Asexual reproduction is by binary or multiple fission (schizogony).

Apis (Greek), Egyptian HAP, HEP, or HAPI, in ancient Egyptian religion, sacred bull deity worshiped at Memphis. The cult of Apis originated at least as early as the 1st dynasty (c. 2925–c. 2775 BC). Like other bull deities, Apis was probably at first a fertility god concerned with the propagation of grain and herds; but he became associated with Ptah (see photograph), the paramount deity of the Memphite area, and also with Osiris (as User-Hapi) and Sokaris, gods of the dead and of the underworld. As Apis-Atum he was associated with the solar cult and was often represented with the sun-disk between his horns.

Much of what is known about Apis comes from Greco-Roman writers. He was black and white and distinguished by special markings. Some ancient writers said that he was begotten by a ray of light from heaven, and others that he was sired by an Apis bull. When a sacred bull died, the calf that was to be his successor was sought and installed in the Apieion at Memphis. His priests drew omens from his behaviour, and his oracle had a wide reputation. When an Apis bull died, it was buried with great pomp at Saqqārah, in underground galleries known in the classical world as the Sara-

Apis, bull deity, painted on the bottom of a wooden coffin, c. 700 BC; in the Roemer und Pelizaeus Museum, Hildesheim, Ger.

Bavaria Verlag

peum. It was probably in Memphis that the worship of Sarapis (after the Greek form Osorapis, a combination of Osiris and Apis in the image of an eastern Greek god) arose under Ptolemy I Soter (305–282 BC). From Alexandria, it spread to become one of the most widespread Oriental cults in the Roman Empire.

Apizaco, city, central Tlaxcala state, east-central Mexico. It lies at 7,900 ft (2,400 m) above sea level in the cool Apizaco valley of the Sierra Madre Oriental. Formerly known as Barrón Escandón, the city is a commercial, manufacturing, and transportation centre. Corn (maize), beans, barley, and wheat, the principal crops of the agricultural hinterland, are processed there. Tanneries, pulque distilleries, textile mills, and railroad repair yards are also located in the city. The main Mexico City–Veracruz railroad line passes through it,

and highways from highland and coastal communities, including Mexico City, 84 mi (135 km) to the west, converge upon the city. It also has an airfield. Pop. (2000 est.) 55,000.

aplastic anemia, also called ANEMIA OF BONE-MARROW FAILURE, disease in which bone marrow fails to produce an adequate number of blood cells. There may be a lack of all cell types (white blood cells, red blood cells, and platelets; this form is called pancytopenia) or of one or more cell types. Rarely, the disease may be congenital (Fanconi syndrome); more commonly it is acquired by exposure to certain drugs (e.g., chloramphenicol) or non-pharmaceutical chemicals (e.g., benzene) or to ionizing radiation. About half of all cases are idiopathic (cause unknown). Aplastic anemia is most common in youth (ages 15 to 30), though it may occur at any age. Onset of the disease may be abrupt, becoming quickly severe and possibly fatal; more commonly it is insidious, running a chronic course of several years. Symptoms of chronic aplastic anemia include weakness and fatigue in the early stages, followed by shortness of breath, headache, fever, and pounding heart. There is usually a waxy pallor, and hemorrhages occur in the mucous membranes, skin, and other organs. If white blood cells (specifically, neutrophils) are lacking, resistance to infection is much lowered and infection becomes the major cause of death. When platelets are very low, bleeding may be severe.

The treatment of choice for severe aplastic anemia is bone marrow transplantation, provided a compatible donor can be found. If transplantation is not practical, treatment involves avoidance of the toxic agent if known, supportive care (administration of fluids, glucose, and proteins, often intravenously), transfusions of blood components, and administration of antibiotics. Spontaneous recovery occurs occasionally.

aplite, also spelled HAPLITE, any intrusive igneous rock of simple composition, such as granite composed only of alkali feldspar, muscovite mica, and quartz; in a more restricted sense, uniformly fine-grained (less than 2 millimetres [0.08 inch]), light-coloured, intrusive igneous rocks that have a characteristic granular texture. Unlike pegmatite, which is similar but coarser grained, aplite occurs in small bodies that rarely contain zones of different minerals. The two rocks often occur together, cutting across or forming lenses (thin-edged strata) within each other, and are assumed to have formed at the same time from similar magmas (molten materials), the aplite magma containing fewer mineralizers and volatiles. See pegmatite.

Apo, Mount, active volcano, south central Mindanao, 20 mi (32 km) west of Davao City; it is the highest point in the Philippines, rising to 9,690 ft (2,954 m). Part of the Cordillera Central, it is covered by a forest of tall, tropical hardwoods; two subsidiary peaks nearly match its height. Mt. Apo National Park, established in 1936, has an area of 199,819 ac (80,864 ha); it is the home of the monkey-eating eagle and features numerous peaks and valleys, as well as Malasita Falls, Sibulao Lake, and the Kisinte Hot Springs.

Apocalypse of John: see Revelation to John.

apocalyptic literature, literary genre that flourished from about 200 BC to about AD 200, especially in Judaism and Christianity. Written primarily to give hope to religious groups undergoing persecution or the stress of cultural upheavals, apocalypses (from the Greek *apokalypsis*: "revelation") describe in cryptic language, understood by believers, the sudden, dramatic intervention of God in history

on behalf of the faithful elect. Accompanying or heralding God's dramatic intervention in human affairs will be cataclysmic events of cosmic proportions, such as a temporary rule of the world by Satan, signs in the heavens, persecutions, wars, famines, and plagues.

Although apocalyptic writers do examine the present, determining whether current afflictions are fulfillments of past apocalyptic prophecies, such writers generally concentrated on the future—on the future overthrow of evil, on the coming of a messianic figure, and on the establishment of the Kingdom of God and of eternal peace and righteousness. The wicked are described as consigned to hell and the righteous or elect as reigning with God or a messiah in a renewed earth or heaven.

The Book of Daniel in the Old Testament and the Revelation to John in the New Testament represent apocalyptic writing, and several intertestamental books contain apocalyptic themes.

Apocalyptic themes have been revived in modern literature and frequently appear in science fiction.

apocalypticism, eschatological (end-time) views and movements that focus on cryptic revelations about a sudden, dramatic, and cataclysmic intervention of God in history; the judgment of all men; the salvation of the faithful elect; and the eventual rule of the elect with God in a renewed heaven and earth. Arising in Zoroastrianism, an Iranian religion founded by the 6th-century-BC prophet Zoroaster, apocalypticism was developed more fully in Judaic, Christian, and Islāmic eschatological speculation and movements. See also eschatology.

Apocrita, one of two suborders of the insect order Hymenoptera, the other being Symphyta. Included in the group are the ants, bees, wasps, braconids, ichneumons, chalcids, nearly all parasitic hymenopterans, and a few other forms. The suborder includes the most highly evolved members of the order and is represented by several thousand species distributed worldwide.

Among most species, the grublike larvae are sedentary forms. They may feed as parasites on other arthropods or within plant structures, or they may be fed by adults within a nest. The base of the adult's abdomen is constricted, a diagnostic feature of the group. The adults feed mainly on plants, although some species are parasites and others are hyperparasites (that is, they feed on insects that are parasitic on other insects).

Although the suborder includes some species that are destructive to crops—for example, the seed chalcids (Eurytomidae)—the majority of species are beneficial to man. Beneficial members include the bee (*q.v.*), which pollinates a great variety of economically important plants; the honeybee (*q.v.*; *Apis*) is also important for the honey it produces; and many species are important as parasites of insect pests. Such parasites include ichneumon, chalcid (*qq.v.*), pteromalid, figitid, ensign wasp (*q.v.*), and bethylid.

apocrypha (from Greek *apokryptein*, "to hide away"), in biblical literature, works outside an accepted canon of scripture. The history of the term's usage indicates that it referred to a body of esoteric writings that were at first prized, later tolerated, and finally excluded. In its broadest sense *apocrypha* has come to mean any writings of dubious authority.

A brief treatment of apocrypha follows. For full treatment, see MACROPAEDIA: Biblical Literature and Its Interpretation.

There are several levels of dubiety within the general concept of apocryphal works in Judeo-Christian biblical writings. Apocrypha per se are outside the canon, not considered divinely inspired but regarded as worthy of study by the faithful. Pseudepigrapha are spu-

rious works ostensibly written by a biblical figure. Deuterocanonical works are those that are accepted in one canon but not in all.

At the time when Greek was the common spoken language in the Mediterranean region, the Old Testament—the Hebrew Bible—was incomprehensible to most of the population. For this reason, Jewish scholars produced the Septuagint, a translation of the Old Testament books from various Hebrew texts, along with fragments in Aramaic, into Greek. That version incorporated a number of works that later, non-Hellenistic Jewish scholarship at the Council of Jamnia (AD 90) identified as being outside the authentic Hebrew canon. The Talmud separates these works as *Sefarim Hizonim* (Extraneous Books).

The Septuagint was an important basis for St. Jerome's translation of the Old Testament into Latin for the Vulgate Bible; and, although he had doubts about the authenticity of some of the apocryphal works that it contained (he was the first to employ the word *apocrypha* in the sense of "noncanonical"), he was overruled, and most of them were included in the Vulgate. On April 8, 1546, the Council of Trent declared the canonicity of nearly the entire Vulgate, excluding only the Third and Fourth Books of Maccabees, the Prayer of Manasseh, Psalm 151, and the First and Second Books of Esdras. Eastern Christendom, meanwhile, had accepted some of the Old Testament apocrypha—Tobit, Judith, the Wisdom of Solomon, and Ecclesiasticus (Wisdom of Jesus the Son of Sirach)—but rejected the rest.

The other apocryphal writings, canonical only to Roman Catholicism, with an exception or two, include the Book of Baruch (a prophet) and the Letter of Jeremiah (often the sixth chapter of Baruch); the First and Second Books of Maccabees; several stories from Daniel, namely, the Song of the Three, Susanna, and Bel and the Dragon; and extensive portions of the Book of Esther.

Old Testament pseudepigrapha are extremely numerous and offer accounts of patriarchs and events, attributed to various biblical personages from Adam to Zechariah. Some of the most significant of these works are the Ascension of Isaiah, the Assumption of Moses, the Life of Adam and Eve, the First and Second Books of Enoch, the Book of Jubilees, the Letter of Aristeas, and the Testaments of the Twelve Patriarchs.

All the New Testament apocrypha are pseudepigraphal, and most of them fall into the categories of acts, gospels, and epistles, though there are a number of apocalypses and some can be characterized as wisdom books. The apocryphal acts purport to relate the lives or careers of various biblical figures, including most of the apostles; the epistles, gospels, and others are ascribed to such figures. Some relate encounters and events in mystical language and describe arcane rituals. Most of these works arose from sects that had been or would be declared heretical, such as, importantly, the Gnostics. Some of them argued against various heresies, and a few appear to have been neutral efforts to popularize the life of some saint or other early leader of the church, including a number of women. In the early decades of Christianity no orthodoxy had been established, and various parties or factions were vying for ascendancy and regularity in the young church. All sought through their writings, as through their preaching and missions, to win believers. In this setting virtually all works advocating beliefs that later became heretical were destined to denunciation and destruction.

In addition to apocryphal works per se, the New Testament includes a number of works and fragments that are described by a second meaning of the term deuterocanonical: "added later." The Letter to the Hebrews attributed to Paul, who died before it was written, is

one of these; others are the letters of James, Peter (II), John (II and III), and Jude, and the Revelation to John. Fragments include Mark 16:9–20, Luke 22:43–44, and John 7:53 and 8:1–11. All are included in the Roman canon and are accepted by the Eastern Church and most Protestant churches.

Heretical movements such as Gnosticism and Montanism spawned a great body of New Testament pseudepigrapha. The existence of such purported scriptures lent great impetus to the process of canonization in the young and orthodox Christian Church. *See also* various apocryphal works cited above.

Apocynaceae, the dogbane family of flowering plants of the gentian order (Gentianales), including more than 150 genera and about

Golden-trumpet (*Allamanda cathartica*)

Walter Chandoha

1,000 species of trees, shrubs, woody vines, and herbs, distributed primarily in tropical and subtropical areas of the world. Members of the family have milky, often poisonous juice; smooth-margined leaves; and flowers in clusters (rarely solitary). The fruit may be berrylike or fleshy but usually is a dry pod (follicle) that splits open at maturity, releasing many winged or tufted seeds.

Garden ornamentals belonging to the family include periwinkle (*Vinca*), oleander (*Nerium*), yellow oleander (*Thevetia*), frangipani (*Plumeria*), Natal plum (*Carissa*), and crepe jasmine (*Tabernaemontana coronaria*). Several species of the genera *Trachelospermum* (especially star jasmine, *T. jasminoides*), *Mandevilla*, and *Allamanda* are attractive woody vines. Dogbane (*Apocynum*) and *Amsonia* sometimes are grown as ornamentals. The gen-

Periwinkle (*Vinca minor*)

Walter Chandoha

era *Adenium* and *Pachypodium* are African succulents with alternate leaves and strangely shaped trunks. The impala lily (*Adenium multiflorum*) is an ornamental shrub with star-shaped flowers and large underground tubers. Arrow poisons are obtained from many plants in the dogbane family, and the poisonous alkaloids of species belonging to the genera *Strophanthus* and *Rauwolfia* (*qq.v.*) also are used in medicines.

apodiform, order of birds (Apodiformes) that comprises the swifts and hummingbirds.

A brief treatment of apodiforms follows. For full treatment, *see* MACROPAEDIA: Birds.

The common characteristic that has swifts and hummingbirds classified together is their mastery of aerial locomotion; they are superb fliers and share some wing modifications that differentiate them from most other birds. The hummingbirds are classed in one suborder, the Trochili, and the approximately 320 species are members of the family Trochilidae. The suborder Apodi, which contains the swifts, is divided into two families, the Apodidae for the true swifts and the Hemiprocnidae for the tree, or crested, swifts.

Hummingbirds are native only to the Western Hemisphere and most species are found in the tropics of northwestern South America. Several species, including the North American ruby-throated hummingbird (*Archilochus colubris*), have adapted to temperate zones, and one, the rufous hummingbird (*Selasphorus rufus*), even ranges into Alaska. The tree swifts are limited in range, inhabiting an area from India through southeast Asia and into the East Indies. The true swifts are the most widespread members of the order, being found throughout the Old and New World wherever the land can support a large enough number of flying insects.

Hummingbird shape is much the same throughout the family. The bee hummingbird of Cuba (*Mellisuga helenae*) is the smallest known species of bird; it is only 2.5 inches (6.4 centimetres) in length. The largest of the family is the giant hummingbird (*Patagona gigas*), which reaches all of 8 in. Variation occurs in the shape and size of the bill and in the ornamental plumage. The bill may be quite short, as in the bearded helmetcrest (*Oxygogon guerini*), or longer than the rest of the body, as in the sword-billed hummingbird (*Ensifera ensifera*). It is often straight but may be down-curved, as in the sicklebills (*Eutoxeres*), or less frequently, upcurved. The shape of the bill is related to the flowers on which each species of hummingbird preferentially feeds. The legs and feet are small, suitable only for perching, not walking. Bright iridescent plumage, especially on the throat, is characteristic of most hummingbirds. The tails of most species are short and simple, but in a few, such as the marvelous spatuletail (*Loddigesia mirabilis*), they are elongated and ornate.

The swifts show a much greater range in size than the hummingbirds, and members of the Old World genus *Apus* can weigh 30 times as much as the 0.2-ounce (5.7-gram) pygmy swiftlet (*Collocalia troglodytes*). The structure which shows the most variation is the tail. In the spine-tailed swifts, including the American chimney swift (*Chaetura pelagica*), the central shafts of the tail feathers extend beyond the flattened vane as pointed spikes. Other swifts have tails that are either squared off, slightly forked, or deeply forked (swallow-tailed). The feet of the true swifts are too weak to use for perching, and they rest by clinging to vertical surfaces with their sharp claws. In the tree swifts the feet are stronger and larger and these birds perch regularly. Adaptations to their exclusive diet of flying insects are the short weak bill and the large mouth.

The swifts are limited in habitat only by the availability of flying insects. Swifts drink by dipping their bills as they fly low over a

body of water. Hummingbirds, being highly specialized to subsist basically on nectar, are restricted to areas where flowering plants are available. This explains the predominant number of species in the seasonless tropics, where different plants are in flower all year. When feeding, a hummingbird hovers over a flower and extends its long tubular tongue to suck up the nectar. In addition to hovering, these birds can fly backwards and occasionally upside down. Many will also eat some insects and spiders, which they capture with their bills.

Hummingbirds and swifts are both able to enter torpor, in which the metabolism slows down and the body temperature drops. This allows the hummingbirds to roost at night without exhausting their energy reserves, supporting their otherwise very high metabolism. It enables the swifts to survive long periods of fasting when aerial foraging is not possible.

Courtship among swifts is completely aerial and copulation takes place while in flight. Nests of tree swifts are frequently simple cups placed on a tree limb. The palm swifts (*Cypsiurus parvus*) glue their nests to the underside of palm leaves with a sticky secretion produced by the salivary glands, and some species glue the eggs into the nest so the wind cannot bounce them out. The nest of one species, the edible-nest swiftlet (*Collocalia fuciphaga*), is constructed almost entirely of this salivary cement; these nests are the basis of the Orient's famous bird's-nest soup. Clutches range from one to six white eggs, with species from the northern regions laying the higher numbers. The Indian house swift, *Apus affinis*, is one of the few birds known to have two distinct breeding seasons per year; it breeds in January and again from late May to June. Incubation in the swifts is shared by both sexes. The naked young are left unattended for longer periods than are most birds as the parents forage for many small insects; however, the young swifts are basically cold-blooded (poikilothermic) during their first few weeks.

Hummingbirds, unlike swifts, are usually polygamous. Territoriality is absent in some species while others may vigorously defend nesting or feeding sites. These birds are typically aggressive and take advantage of their great manoeuvrability in the air to drive off hawks and other large predators. Most courtship displays are aerial, although in those of the drably coloured hermits (*Phaethornis*) singing is important. In some species, leks—areas of communal male display—occur. Hummingbird nests are typically situated on a branch and composed of vegetable fibre, lichens, bark fragments, and spider webs. The female incubates her clutch of two white eggs and cares for the young alone. To feed the hatchlings she thrusts her bill deeply into a young bird's throat and regurgitates.

Apollinaire, Guillaume, pseudonym of WILHELM APOLLINARIS DE KOSTROWITZKI (b. Aug. 26, 1880, Rome?—d. Nov. 9, 1918, Paris), poet who in his short life took part in all the avant-garde movements that flourished in French literary and artistic circles at the beginning of the 20th century and who helped to direct poetry into unexplored channels.

The son of a Polish *émigrée* and an Italian officer, he kept his origins secret. Left more or less to himself, he went at the age of 20 to Paris, where he led a bohemian life. Several months spent in Germany in 1901 had a profound effect on him and helped to awaken him to his poetic vocation. He fell under the spell of the Rhineland and later recaptured the beauty of its forests and its legends in his poetry. More important, he fell in love with a young Englishwoman, Annie Playden, whom he pursued, unsuccessfully, as far as London;

his romantic disappointment inspired him to write his famous "Chanson du mal-aimé" ("Song of the Poorly Loved").

Apollinaire, drawing by Pablo Picasso from the frontispiece to *Calligrammes*, 1918

H. Roger Viollet

After his return to Paris, Apollinaire became well known as a writer and a habitu  of the caf s patronized by literary men. He also made friends with some young painters who were to become famous—Maurice de Vlaminck, Andr  Derain, Raoul Dufy, and Pablo Picasso; he introduced his contemporaries to Henri Rousseau's paintings and to African sculpture; and with Picasso, he applied himself to the task of defining the principles of a Cubist aesthetic in literature as well as painting. His *Peintures cubistes* appeared in 1913 (*Cubist Painters*, 1944).

His first volume, *L'Enchanteur pourrissant* (1909), is a strange dialogue in poetic prose between the magician Merlin and the nymph Viviane. In the following year a collection of vivid stories, some whimsical and some wildly fantastic, appeared under the title *L'H r siarque et Cie* (1910). Then came *Le Bestiaire* (1911), in mannered quatrains. But his poetic masterpiece was *Alcools* (1913; Eng. trans., 1964). In these poems he relived all his experiences and expressed them sometimes in alexandrines and regular stanzas, sometimes in short unrhymed lines, and always without punctuation.

In 1914 Apollinaire enlisted, became a second lieutenant in the infantry, and received a head wound in 1916. Discharged, he returned to Paris and published a symbolic story, *Le Po te assassin * (1916; *The Poet Assassinated*, 1923), and more significantly, a new collection of poems, *Calligrammes* (1918), dominated by images of war and his obsession with a new love affair. Weakened by war wounds, he died of Spanish influenza.

His play *Les Mamelles de Tir sias* was staged the year before he died (1917). He called it surrealist, believed to be the first use of the term. Francis Poulenc turned the play into a light opera (first produced in 1947).

In his poetry Apollinaire made daring, even outrageous, technical experiments; his *calligrammes*, thanks to an ingenious typographical arrangement, are designs as well as poems. More generally, Apollinaire set out to create an effect of surprise or even astonishment by means of unusual verbal associations and, because of this, could be called the herald of Surrealism.

Apollinaris THE YOUNGER, Latin APOLLINARIUS (b. c. 310—d. c. 390), bishop of Laodicea who developed the heretical position concerning the nature of Christ called Apollinarianism. With his father, Apollinaris the Elder, he reproduced the Old Testament in the form of Homeric and Pindaric poetry and the New Testament in the style of Platonic dialogues after the Roman emperor Julian had forbidden Christians to teach the classics.

Apollinaris denied the existence in Christ of a rational human soul, a position he took to combat Arianism (see Arius). Excommunicated from the church for his views, Apollinaris was readmitted but in 346 excommunicated a second time. Nevertheless the Nicene congregation at Laodicea chose him as bishop (c. 361). Skilled in logic and Hebrew and a teacher of rhetoric, Apollinaris also lectured at Antioch c. 374.

Apollinopolis (Egypt): see Idf .

Apollo, byname PHOEBUS, in Greek religion, a deity of manifold function and meaning, the most widely revered and influential of all the Greek gods. Though his original nature is obscure, from the time of Homer onward he was the god of divine distance, who sent or threatened from afar; the god who made men aware of their own guilt and purified them of it; who presided over religious law and the constitutions of cities; who communicated to man through prophets and oracles his knowledge of the future and the will of his father, Zeus. Even the gods feared him, and only his father and his mother, Leto, could endure his presence. Distance, death, terror, and awe were summed up in his symbolic bow; a gentler side of his nature, however, was shown in his other attribute, the lyre, which proclaimed the joy of communion with Olympus (the home of the gods) through music, poetry, and dance. In humbler circles he was also a god of crops and herds, primarily as a divine bulwark against wild animals and disease, as his epithet Alexikakos (Averter of Evil) indicates. His forename Phoebus means "bright" or "pure," and the view became current that he was connected with the sun. See Helios.

Allian—Art Resource/EB Inc

Among Apollo's other epithets was Nomios (Herdsman), and he is said to have served King Admetus of Pherae in the lowly capacities of groom and herdsman as penance for slaying Zeus's armourers, the Cyclopes. He was also called Lyceus, presumably because he protected the flocks from wolves (*lykoi*); because herdsman and shepherds beguiled the hours with music, scholars have argued that this was Apollo's original role.

Though the most Hellenic of all gods, Apollo apparently was of foreign origin, coming either from somewhere north of Greece or from Asia. Traditionally, Apollo and his twin, Artemis, were born on the isle of Delos. From there Apollo went to Pytho (Delphi), where he slew Python, the female dragon that guarded the area. He established his oracle by taking on the guise of a dolphin, leaping aboard a

Cretan ship, and forcing the crew to serve him. Thus Pytho was renamed Delphi after the dolphin (*delphis*), and the Cretan cult of Apollo Delphinus superseded that previously established there by Earth (Gaea). During the Archaic period (8th to 6th century BC), the fame of the Delphic oracle spread as far as Lydia in Anatolia and achieved pan-Hellenic status. The god's medium was the Pythia, a local woman over fifty years old, who, under his inspiration, delivered oracles in the main temple of Apollo. The oracles were subsequently interpreted and versified by priests. Other oracles of Apollo existed on the Greek mainland, Delos, and in Anatolia, but none rivalled Delphi in importance.

Of the Greek festivals in honour of Apollo, the most curious was the octennial Delphic Stepterion, in which a boy reenacted the slaying of the Python and was temporarily banished to the Vale of Tempe.

Although Apollo had many love affairs, they were mostly unfortunate: Daphne, in her efforts to escape him, was changed into a laurel, his sacred shrub; Coronis (mother of Asclepius) was shot by Apollo's twin, Artemis, when Coronis proved unfaithful; and Cassandra (daughter of King Priam of Troy) rejected his advances and was punished by being made to utter true prophecies that no one believed.

In Italy Apollo was introduced at an early date and was primarily concerned, as in Greece, with healing and prophecy; he was highly revered by the emperor Augustus because the Battle of Actium (31 BC) was fought near one of his temples. In art Apollo was represented as a beardless youth, either naked or robed, and often holding either a bow or a lyre.

Apollo program, Moon-landing project executed by the United States National Aeronautics and Space Administration in the 1960s and 1970s. The Apollo program was announced in May 1961, but the choice among competing techniques for achieving a Moon landing and return was not resolved until considerable further study. The method ultimately employed was that of lunar-orbit rendezvous, by which a powerful launch vehicle (Saturn V) placed a 50-ton spacecraft in a lunar trajectory. Several launch vehicles, essentially large rockets, and accompanying spacecraft, were built. The Apollo spacecraft were supplied with a relatively slight rocket power of their own, capable of permitting them to brake on approach to the Moon and go into a lunar orbit. They also possessed the capability of releasing a component of the spacecraft, the Lunar Module (LM), carrying its own rocket power, to land persons on the Moon and bring them back to the lunar orbiting Apollo craft.

The first manned Apollo flight was delayed by a tragic accident, a fire that broke out in the spacecraft during a launch rehearsal, killing three astronauts. On Oct. 11, 1968, following several unmanned Earth-orbit flights, Apollo 7 made a 163-orbit flight carrying a full crew of three astronauts. Apollo 8 carried out the first step of manned lunar exploration; from Earth orbit it was injected into a lunar trajectory, completed lunar orbit, and returned safely to Earth. Apollo 9 carried out a prolonged mission in Earth orbit to check out the Lunar Module. Apollo 10 journeyed to lunar orbit and tested the LM to within 9½ miles (15 kilometres) of the Moon's surface. Apollo 11, in July 1969, climaxed the step-by-step procedure with a lunar landing; the astronaut Neil Armstrong became the first human to set foot on the Moon's surface.

Apollo 13, launched in April 1970, suffered an accident caused by an explosion in an oxygen tank but returned safely to Earth. Remaining Apollo missions carried out extensive exploration of the lunar surface, collecting large numbers of samples of Moon rocks and installing many instruments for scientific re-

search, such as the solar wind experiment, and the seismographic measurements of the lunar surface. Apollo 17, the final flight of the program, took place in December 1972.

Apollodorus (fl. 5th century BC), Athenian painter thought to have been the first to graduate light and colour, that is, to shade his paintings. For this reason he was known, in his own day, as "Sciagraphos," or "Shadow Painter." Pliny called him the "first to give his figures the appearance of reality."

Apollodorus' paintings are now all lost, though ancient sources mention several of his works. Among them, all in Athens, were: "Odysseus," "A Priest at Prayer," and "Ajax Struck by Lightning."

Apollodorus OF ATHENS (fl. 140 BC), Greek scholar of wide interests who is best known for his *Chronicle* of Greek history. A pupil of the scholar Aristarchus, he left Alexandria about 146 for Pergamum and eventually settled at Athens. The *Chronicle*, written in iambic trimeter, commonly used in Greek comedy, covers the period from the fall of Troy (1184 BC) to 144 BC and was later continued to 119 BC. Apollodorus' other works include a treatise *On the Gods*; one on the Homeric catalogue of ships, used by Strabo in his *Geography*; and critical and grammatical writings. A compendium to Greek mythology, called *The Library*, extant under his name, is, in fact, not by him.

Apollodorus OF DAMASCUS (fl. early 2nd century AD), Greek engineer and architect who worked primarily for the Roman emperor Trajan (reigned 98–117). He was banished by the emperor Hadrian and executed c. AD 130. The most famous works associated with him are the designs for Trajan's Forum in Rome and for Trajan's Column.

Apollonius DYSCOLUS (Greek: the Crabbed) (fl. 2nd century AD), Greek grammarian who was reputedly the founder of the systematic study of grammar. His life was passed at Alexandria during the reigns of the Roman emperors Hadrian and Antoninus Pius. Priscian, the Latin grammarian, styled him *grammaticorum princeps* ("prince of grammarians") and used his work as the basis for his own. Four of Apollonius' works are extant: *On Syntax* and three smaller treatises, *On Pronouns*, *On Conjunctions*, and *On Adverbs*.

Apollonius OF PERGA (b. c. 262 BC, Perga, Pamphylia, Anatolia—d. c. 190, Alexandria), mathematician, known by his contemporaries as "The Great Geometer," whose treatise *Conics* is one of the greatest scientific works from the ancient world. Most of his other treatises were lost, although their titles and a general indication of their contents were passed on by later writers, especially Pappus of Alexandria (fl. c. AD 320).

As a youth Apollonius studied in Alexandria (under the pupils of Euclid, according to Pappus) and subsequently taught at the university there. He visited Pergamum, capital of a Hellenistic kingdom in western Anatolia, where a university and library similar to those in Alexandria had recently been built. While at Pergamum he met Eudemus and Attalus, and he wrote the first edition of *Conics*. He addressed the prefaces of the first three books of the final edition to Eudemus and the remaining volumes to Attalus, whom some scholars identify as King Attalus I of Pergamum.

It is clear from Apollonius' allusions to Euclid (fl. c. 295 BC), Conon of Samos (fl. c. 250 BC), and Nicoteles of Cyrene (fl. c. 250 BC) that he made the fullest use of his predecessors' works. Books 1–4 contain a systematic account of the essential principles of conics, which for the most part had been previously set forth by Euclid, Aristaeus (fl. c. 320 BC), and Menaechmus (fl. c. 350 BC). A number of theorems in Book 3 and the greater part of

Book 4 are new, however, and he introduced the terms parabola, ellipse, and hyperbola. Books 5–7 are clearly original. His genius takes its highest flight in Book 5, in which he considers normals as minimum and maximum straight lines drawn from given points to the curve (independently of tangent properties), discusses how many normals can be drawn from particular points, finds their feet by construction, and gives propositions determining the centre of curvature at any point and leading at once to the Cartesian equation of the evolute of any conic.

The first four books of the *Conics* survive in the original Greek and the next three in Arabic translation. Book 8 is lost. The only other extant work of Apollonius is *Cutting Off of a Ratio* (or *On Proportional Section*), in an Arabic translation. Pappus mentions five additional works, *Cutting Off of an Area* (or *On Spatial Section*), *On Determinate Section*, *Tangencies*, *Vergings* (or *Inclinations*), and *Plane Loci*.

Tangencies embraced the following general problem: given three things, each of which may be a point, straight line, or circle, construct a circle tangent to the three. Sometimes known as the problem of Apollonius, the most difficult case arises when the three given things are circles.

Of the other works of Apollonius referred to by ancient writers, one, *On the Burning Mirror*, concerned optics. Apollonius demonstrated that parallel light rays striking a spherical mirror would not be reflected to the centre of sphericity, as was previously believed. The focal properties of the parabolic mirror were also discussed. A work entitled *On the Cylindrical Helix* is mentioned by Proclus (c. AD 410–485). Apollonius also wrote *Comparison of the Dodecahedron and the Icosahedron*, considering the case in which they are inscribed in the same sphere. According to Eutocius (fl. c. AD 500), in Apollonius' work *Quick Delivery*, closer limits for the value of π (pi) than the $3\frac{1}{7}$ and $3\frac{10}{71}$ of Archimedes were calculated. In a work of unknown title Apollonius developed his system of tetrads, a method for expressing and multiplying large numbers. His *On Unordered Irrationals* extended the theory of irrationals originally advanced by Eudoxus of Cnidus and found in Book 10 of Euclid's *Elements*.

Lastly, from references in Ptolemy's *Almagest*, it is known that Apollonius introduced the systems of eccentric and epicyclic motion to explain planetary motion. Of particular interest was his determination of the points where a planet appears stationary.

Apollonius OF RHODES (b. c. 295 BC), Greek poet and grammarian who was the author of the *Argonautica*.

The two lives contained in the Laurentian manuscript of the *Argonautica* say that Apollonius was a pupil of Callimachus; that he gave a recitation of the *Argonautica* at Alexandria; and that when this proved a failure he

retired to Rhodes. The first life adds the detail that the poet was still an adolescent when this happened, though it had previously said that he turned late to writing poetry. Both lives say that the *Argonautica* was well received in Rhodes, and the second cites a report that Apollonius returned to Alexandria and was appointed chief librarian. Another work has him succeed Eratosthenes in this post. But in a list of Alexandrian librarians on a late 2nd-century AD papyrus (Oxyrhynchus Papyrus 1241), Apollonius succeeds Zenodotus and precedes Eratosthenes. If this evidence is accepted it may be conjectured that Apollonius became librarian c. 260 BC and continued as such until c. 247, when he fell out of favour under the new king, Ptolemy Euergetes, and retired to Rhodes.

In the *Argonautica*, an epic in four books on the voyage of the Argonauts, Apollonius adapted the language of Homer to the needs of a romantic epic with considerable success: in recounting Medea's love for Jason, he shows a capacity for sympathetic analysis not found in earlier Greek literature. Apollonius often holds the reader by his fresh handling of old episodes, his suggestive similes, and his admirable descriptions of nature. Besides the *Argonautica*, Apollonius wrote epigrams and poems on the foundations (*Ktiseis*) of cities, most of which are lost. As a grammarian, Apollonius is credited with a work "against Zenodotus" and commentaries on several Greek poets.

Apollonius OF TRALLES (fl. 2nd century BC), Greek sculptor from the province of Caria, in Asia Minor, known for his execution in collaboration with his brother Tauriscus of a marble group known as the "Farnese Bull." The work represented Zethus and Amphion, the twin builders of Thebes, tying their stepmother, Dirce, to the horns of a wild bull in punishment for her torment of their mother, Antiope.

Apollonius OF TYANA (fl. 1st century AD, Tyana, Cappadocia), a Neo-Pythagorean who became a mythical hero during the time of the Roman Empire. Empress Julia Domna instructed the writer Philostratus to write a biography of Apollonius, and it is speculated that her motive for doing so stemmed from her desire to counteract the influence of Christianity on Roman civilization. The biography portrays a figure much like Christ in temperament and power and claims that Apollonius performed certain miracles. It is believed that most of the biography is based more on fiction than fact. Many of the pagans in the Roman Empire believed what was said in this work, and it kindled religious feeling in many of them. To honour and worship Apollonius, they erected shrines and other memorials.

Apollonius OF TYRE, chief personage in a medieval Latin romance of unknown authorship, which may be assumed to derive from a lost Greek original. The story enjoyed long and widespread popularity in European literature, and versions of it exist in almost every European language. The story tells of the separation of Apollonius from his wife and daughter (whom he thinks dead) and his ultimate reunion with them after many travels.

The Greek original on which this story is thought to be based probably dates from the 3rd century AD. The Latin version is first mentioned in the second half of the 6th century by Venantius Fortunatus, a Christian poet and bishop. The survival of numerous Latin manuscripts (the earliest dating from the 9th or 10th century) testifies to its popularity in the Middle Ages. The most widespread versions in the Middle Ages include one by Godfrey of Viterbo in his *Pantheon*, a late

Apollonius of Rhodes, bronze bust by an unknown artist, in the Museo Archeologico, Florence
By courtesy of the Museo Archeologico, Florence

12th-century verse rendering that treated the story as authentic history, and one contained in the *Gesta Romanorum*, a 14th-century collection of folktales. An Anglo-Saxon translation (the first English vernacular version) was made in the 11th century, and the poet John Gower used the tale as an example of the seventh deadly sin (Sloth) in his late 14th-century poem *Confessio amantis*. Shakespeare (although changing his hero's name) used the story as the basis of his play *Pericles*.

Apollonius THE ATHENIAN (fl. 1st century BC), sculptor known only by his signatures on the marble "Belvedere Torso," now in the Vatican, and the bronze "Boxer," now in the Museo Nazionale Romano of Rome. At one time these sculptures were thought to be 1st-

"The Boxer," Roman bronze copy of Greek sculpture by Apollonius the Athenian, 1st century BC; in the Museo Nazionale Romano, Rome

Alinari—Art Resource/EB Inc

century originals. Now it is believed they are fine 1st-century copies of original 2nd-century works; although the inscriptions are datable to the 1st century, the style of the sculptures is similar to that of the great altar at Pergamum, a key monument of the 2nd century. Thus, Apollonius appears to have been one of the most talented copyists of his time.

apologetics, in Christianity, the intellectual defense of the truth of the Christian religion, usually considered a branch of theology. In Protestant usage, apologetics can be distinguished from polemics, in which the beliefs of a particular Christian sect are defended. Roman Catholics, however, use the term to mean defense of Catholic teaching as a whole and identify apologetics with fundamental theology.

Apologetics has traditionally been positive in its direct argument for Christianity and negative in its criticism of opposing beliefs. Its function is both to fortify the believer against his personal doubts and to remove the intellectual stumbling blocks that inhibit the conversion of unbelievers. Apologetics has steered a difficult course between dogmatism, which fails to take seriously the objections of non-Christians, and the temptation to undermine the strength of defense by granting too much to the skeptic. Apologetics has rarely been taken as providing a conclusive proof of Christianity; many apologists believe that to insist on such proof is to sacrifice the supernatural element to purely rational considerations. Some theologians have been skeptical about the value of apologetics to a religion based on faith.

In the New Testament, the thrust of apolo-

getics was defense of Christianity as the culmination of the Jewish religion and its prophecies concerning a messiah. In the early church, the Apologists, such as Justin Martyr and Tertullian, defended the moral superiority of Christianity over paganism and pointed out Christianity's fulfillment of Old Testament prophecies. Origen, a 2nd–3rd-century Alexandrian philosophical theologian, stressed the supernatural witness of the Holy Spirit in Christian belief. The Platonic theologian Augustine, around the turn of the 4th century, presented Christianity as God's answer to the fall of the Roman Empire, which the sin of man was effecting.

In the later Middle Ages, apologists focussed on Christianity's superiority over the rival religions of Judaism and Islam. In the 13th century, however, Thomas Aquinas developed a still-influential defense of belief in God based on Aristotelian theories of a first cause of the universe.

During the Protestant Reformation apologetics was substantially replaced by polemics, in which many sects sought to defend their particular beliefs rather than Christianity as a whole. In the 18th century, Joseph Butler, an English bishop, met the rising challenge of Deism in the wake of advancing science by arguing that a supernatural Christianity was at least as reasonable and probable as any scientific doctrine could be. A later Englishman, William Paley, argued that a universe exhibiting design must have a Designer, much as a watch implies a watchmaker.

In the 19th century the historical reliability of the Gospels came under attack, and apologists stressed the difficulty of accounting for the Resurrection of Jesus and the rapid spread of Christianity if supernaturalism were denied. Moral arguments for Christianity based on the philosophy of religion of the German philosopher Immanuel Kant also gained prominence as attacks on traditional historical and metaphysical apologetics increased. Further objections to Christianity based on the theory of evolution, the views of the German philosopher Friedrich Nietzsche, Marxism, and psychoanalysis have been met by apologists either by attempts to refute the fundamentals on which they are based, or by turning some aspects of the criticisms into new arguments favourable to Christianity.

In the 20th century such Protestant theologians as the Germans Rudolf Bultmann and Paul Tillich abandoned the attempt to preserve the literal historical truth of the Gospels and focussed on presenting Christianity as the best answer to the existential needs and questions of man. Other Protestants stress the need to make the ancient stories and symbols of Christianity meaningful to modern man in a "post-Christian" era dominated by Materialistic ideologies. The German scholar Karl Barth, however, one of the century's most influential theologians, expressed skepticism about the whole task of the apologetical system, insisting that Christianity must be rooted exclusively in faith. The Roman Catholic apologetical system, that of Thomas Aquinas and his intellectual successors, has been profoundly influenced in the 20th century by the second Vatican Council (*see* Vatican Council, second). Some apologetical functions have been absorbed by "fundamental theology." Contemporary apologetics in the Roman communion focusses principally on the community of believers, whose faith is under constant challenge by numerous competing views and value systems.

Apologist, any of the Christian writers, primarily in the 2nd century, who attempted to provide a defense of Christianity and criticisms of Greco-Roman culture. Many of their writings were addressed to Roman emperors, and it is probable that the writings were actually sent to government secretaries who were

empowered to accept or reject them. Under these circumstances, some of the apologies assumed the form of briefs written to defend Christians against the accusations current in the 2nd century, especially the charges that their religion was novel or godless or that they engaged in immoral cultic practices.

The Apologists usually tried to prove the antiquity of their religion by emphasizing it as the fulfillment of Old Testament prophecy; they argued that their opponents were really godless because they worshipped the gods of mythology; and they insisted on the philosophical nature of their own faith as well as its high ethical teaching. Their works did not present a complete picture of Christianity because they were arguing primarily in response to charges by their opponents.

The Greek Apologists include Quadratus, Aristides, Justin Martyr, Tatian, Apollinaris (bishop of Hierapolis), Melito, Athenagoras, Theophilus, and Clement of Alexandria. Latin Apologists in the 2nd century included Marcus Minucius Felix and Tertullian.

The few early manuscripts of the works of the early Apologists that have survived owe their existence primarily to Byzantine scholars. In 914 Arethas, bishop of Caesarea Cappadociae, had a collection of early apologies copied for his library. Many of the later manuscripts were copied in the 16th century, when the Council of Trent was discussing the nature of tradition. The genuine writings of the Apologists were virtually unknown, however, until the 16th century.

apology, autobiographical form in which a defense is the framework for a discussion by the author of his personal beliefs and viewpoints. An early example dating from the 4th century BC is Plato's *Apology*, a philosophical dialogue dealing with the trial of Socrates, in which Socrates answers the charges of his accusers by giving a brief history of his life and his moral commitment. Such an apology is usually a self-justification. Among the famous apologies of Western literature are *Apologie de Raimond Sebond* (1580), an essay by Montaigne, who uses a defense of the beliefs of a 15th-century Spaniard as a pretext for presenting his own skeptical views on the futility of reason; *An Apology for the Life of Mr. Colley Cibber (Comedian)* (1740), in which the 18th-century English actor-manager answers his critic Alexander Pope with a summary of the achievements of his long career that is also one of the best theatrical histories of the period; and *Apologia pro Vita Sua* (1864; later retitled *History of My Religious Opinions*), by Cardinal Newman, a spiritual autobiography in which the general religious principles that inspired Newman's conversion to the Roman Catholic Church are examined.

Apology of the Augsburg Confession, one of the confessions of Lutheranism, a defense and elaboration of the Augsburg Confession, written by the Reformer Philipp Melancthon in 1531. The first version of the Apology was hastily written and presented to Emperor Charles V on Sept. 22, 1530, at the Diet of Augsburg, after the Emperor had declared that the Confutation (Aug. 3, 1530), prepared by Catholic theologians to refute the Augsburg Confession (June 25, 1530), properly presented his Catholic faith. The Emperor demanded that the Reformers return to the Catholic Church, and he refused to accept the Apology when it was presented to him.

After Melancthon returned to Wittenberg, he obtained a copy of the Confutation and decided that a more complete reply to the arguments of the Catholic theologians was necessary. He rewrote and expanded the Apology to more clearly and completely explain the faith of the Reformers. The Latin edition was completed in April or May and a German translation by Justus Jonas was published in the autumn of 1531. Luther and others soon

recognized the Apology as an excellent exposition of the Lutheran faith. It was cited at various meetings and conferences and was finally included in the *Book of Concord* (1580), a collection of doctrinal standards of Lutheranism.

Seven times longer than the Augsburg Confession, the Apology is considered one of the most brilliant of the Reformation theological works. Melancthon's broad knowledge of Scripture, theology, history, and linguistics is evident in it. About one-third of the work is concerned with the problem of justification, while other subjects treated include the church, human tradition, the invocation of saints, marriage of priests, the mass, monastic vows, penitence, and original sin.

apomixis, reproduction by special generative tissues without fertilization. It includes parthenogenesis in animals, in which the new individual develops from the unfertilized egg, and apogamy in certain plants, in which the generative tissue may be the sporophyte or the gametophyte. Apomixis provides for the perpetuation of traits favourable to individual survival but eliminates the longer-term evolutionary advantage of biparental inheritance.

aponeurosis, a flat sheet or ribbon of tendon-like material that anchors a muscle or connects it with the part that the muscle moves. The aponeurosis is composed of dense fibrous connective tissue containing fibroblasts (collagen-secreting spindle-shaped cells) and bundles of collagenous fibres in ordered arrays. Aponeuroses are structurally similar to tendons and ligaments.

apophyllite, potassium-calcium fluoride-silicate mineral that is related structurally to the zeolite family of aluminosilicates. Like the zeolites, it has a high water content, although apophyllite has no aluminum in its chemical composition, which is approximately represented by the formula $\text{Ca}_4\text{KFSi}_8\text{O}_{20} \cdot 8\text{H}_2\text{O}$. In many ways it is more like the micas. It is usually found as glassy, white to grayish crystals with zeolite minerals in basalt, granite, and gneiss, as in Trentino, Italy; Belfast, N.Ire.; the Faroe Islands; Kimberley, S.Af.; and Guanaquato, Mex. For detailed physical properties, see silicate mineral (table).

Apopis, also called APEP, APEPI, or REREK, ancient Egyptian demon of chaos, who had the form of a serpent and, as the foe of the sun god, Re, represented all that was outside the ordered cosmos. Although many serpents symbolized divinity and royalty, Apopis threatened the underworld and symbolized evil. Each night Apopis encountered Re at a particular hour in the sun god's ritual journey through the underworld in his divine bark. Seth, who rode as guardian in the front of Re's bark, attacked him with a spear and slew him, but the next night Apopis, who could not be finally killed, was there again to attack Re. The Egyptians believed that they could help maintain the order of the world and assist Re by performing rituals against Apopis.

Apopis I, Apopis also spelled APOPHIS, or APOPI, last great Hyksos king of Egypt (reigned c. 1585-42 BC), who initially controlled most of Egypt but was driven back northward to the vicinity of his capital in the Nile River delta by the successive attacks of the Theban pharaohs.

Apopis is attested in Upper Egypt by stone fragments from Al-Gabalayn that show his name surrounded by the sun disks of the solar god, Re. A story concerning Apopis and the Theban king Seqenenre (*q.v.*) shows that the Thebans were vassals of the Hyksos ruler. Egyptians and Hyksos peacefully coexisted for some time, as the Thebans grazed their cattle in the Nile delta, which was ruled by the Hyksos.

Apopis quarreled with Seqenenre, and war may have erupted. The Theban king's mummy

displays terrible head wounds. His successor, Kamose, declared a Middle Egyptian town as his northern frontier. He carried on the war, as is shown by two monuments from Thebes, and drove the Hyksos northward to the vicinity of Memphis (near Cairo). A Theban fleet also sailed by Avaris, Apopis' delta capital.

Apopis reacted by calling on his ally to the south, the Cushite prince, to attack the Thebans in their rear. His messenger, however, was intercepted, and his plan was thwarted by Kamose. Some time soon after this raid, but before the final Hyksos expulsion, Apopis died. Contrary to later Egyptian propaganda, he honoured the sun god, Re, and had many collaborators in Middle and Lower Egypt.

apoplexy (medicine): see stroke.

apoptosis, also called PROGRAMMED CELL DEATH, in biology, a mechanism that allows cells to self-destruct when stimulated by the appropriate trigger. Apoptosis is initiated for various reasons, such as when a cell is no longer needed within the body or when it becomes a threat to the health of the organism. Apoptosis is necessary in embryonic development as well as in the daily maintenance of a mature organism. The aberrant inhibition or initiation of apoptosis contributes to many disease processes, including cancer.

Embryologists in the early 20th century were familiar with the process of programmed cell death. They observed that as an embryo develops, many of its cells are sacrificed to create the final form of the organism. Not until 1972, however, did researchers John F.R. Kerr, Andrew H. Wyllie, and Alastair Currie recognize the broader significance of this mechanism. They coined the term *apoptosis* from the Greek word meaning "falling off," as leaves do in autumn, to describe this natural, timely death of cells. Apoptosis is distinguished from an alternate form of cell death, called necrosis, that results from injury.

Apoptosis is a normal physiological process that offsets cell proliferation. It is a genetically programmed event that can be set in motion by a variety of internal or external stimuli. A signal activates genes in the cell's suicide pathway which encode the proteins that destroy the cell's structural proteins and genetic material. A number of morphological changes occur in the apoptotic cell—*e.g.*, the cell begins to shrivel and pull away from other cells, bubblelike formations appear on its surface, and chromatin (chromosomal DNA and protein) in the cell's nucleus condenses. The cell then either is consumed by other cells or breaks up into smaller pieces that are engulfed by scavenger cells. Cells in virtually all tissues may be sacrificed through apoptosis for the good of the organism. For example, the cells of the uterine wall undergo programmed death in the monthly menstrual cycle.

Various phenomena can disturb the regulation of the cell death pathway, causing too many or too few cells to die. Many types of disease result from such disruptions. If, for example, a mutation occurs in a gene that induces apoptosis, such as the tumour-suppressor gene p53, the cell that harbours the gene may fail to respond to the cue to die. As a result the cell may proliferate uncontrollably and form a cancerous tumour. In other cases a virus may interfere with the regulation of apoptosis, inducing healthy cells to die.

aposematic mechanism, biological means by which a dangerous, or noxious, organism advertises its dangerous nature to potential predators. The predator, having recognized the dangerous organism as an unfavourable prey, thereupon desists from attacking it. Aposematic, or warning, mechanisms have evolved along with protective systems; it is advantageous for the protected organism not to risk the injury that is likely to occur in even a successfully repelled attack by a predator.

The most common aposematic mechanism is the possession of bright, contrasting colours, such as the black and yellow of many wasps and the red of ladybird beetles. Other organisms, such as the North American rattlesnakes, employ acoustic warning systems.

aposiopesis (Greek: "becoming silent"), a speaker's deliberate failure to complete a sentence. Aposiopesis usually indicates speechless rage or exasperation, as in "Why, you . . ." and sometimes implies vague threats as in, "Why, I'll . . ." The listener is expected to complete the sentence in his mind. In ancient Greek rhetoric, the aposiopesis occasionally takes the form of a pause before a change of subject or a digression.

apostasy, the total rejection of Christianity by a baptized person who, having at one time professed the faith, publicly rejects it. It is distinguished from heresy, which is limited to the rejection of one or more Christian doctrines by one who maintains an overall adherence to Jesus Christ.

A celebrated controversy in the early church concerned sanctions against those who had committed apostasy during persecution and had then returned to the church when Christians were no longer being persecuted. Some early Christian emperors added civil sanctions to ecclesiastical laws regarding apostates. Certain church theologians of the 4th and 5th centuries considered apostasy to be as serious as adultery and murder. In the 20th century, the Roman Catholic Code of Canon Law still imposed the sanction of excommunication for those whose rejection of the faith fitted the technical definition of apostasy. But the absence of civil sanctions and an increasing tolerance of divergent viewpoints have tended increasingly to mitigate the reaction of believers to those who reject Christianity.

The term apostasy has also been used to refer to those who have abandoned the monastic and clerical states without permission.

Apostle (from Greek *apostolos*, "person sent"), any of the 12 disciples chosen by Jesus Christ; the term is sometimes also applied to others, especially Paul, who was converted to Christianity a few years after Jesus' death. In Luke 6:13 it is stated that Jesus chose 12 from his disciples "whom he named apostles," and in Mark 6:30 the Twelve are called Apostles when mention is made of their return from the mission of preaching and healing on which Jesus had sent them. The full list of the Twelve is given with some variation in Mark 3, Matthew 10, and Luke 6 as: Peter; James and John, the sons of Zebedee; Andrew; Philip; Bartholomew; Matthew; Thomas; James, the son of Alphaeus; Thaddeus, or Judas, the son of James; Simon the Cananaean, or the Zealot; and Judas Iscariot.

The privileges of the Twelve were to be in continual attendance on their master and to be the recipients of his special teaching and training. At least once they were sent on a special mission, two by two, to announce the imminence of the messianic Kingdom (Mark 6: compare Matthew 10; Luke 9). Three of them, Peter, James, and John, formed an inner circle who alone were permitted to witness such events as the raising of Jairus' daughter (Mark 5:37; Luke 8:51), the Transfiguration (Mark 9; Matthew 17; Luke 9), and the agony of Jesus in the Garden of Gethsemane (Mark 14:33; Matthew 26:37).

Special importance seems to have been attached to the number 12, which some scholars interpret as a reference to the 12 tribes of Israel. When a gap had been left by the defection and death of the traitor Judas Iscariot, immediate steps were taken to fill it by the election of Matthias (Acts 1). It is to members

of this band of 12 that the word Apostle is usually applied in Acts.

Paul himself claimed the title of Apostle, apparently on the ground that he had seen the Lord and received a commission directly from him. This appears to be in agreement with the condition in Acts that a newly appointed Apostle should be capable of giving eyewitness testimony to the Lord's Resurrection. According to some early Christian writers, however, some were called apostles after the period covered by the New Testament. The word also has been used to designate a high administrative or ecclesiastical officer.

Apostle Islands National Lakeshore, national lakeshore in northwestern Wisconsin, U.S., at the southwestern end of Lake Superior. Established in 1970, it consists of 21 islands and a 12-mile (19-kilometre) strip of the adjacent Bayfield Peninsula, covering a total area of 108 square miles (281 square km). The islands are noted for high cliffs of sandstone, most from 10 to 30 feet (3 to 9 m) in height but reaching extremes of 60 feet (18 m), with many wave-formed arches and caverns.

Apostle of the North: see Gilpin, Bernard.

Apostles' Creed, also called APOSTOLICUM, a statement of faith used in the Roman Catholic, Anglican, and many Protestant churches. It is not officially recognized in the Eastern Orthodox churches. According to tradition, it was composed by the 12 Apostles, but it actually developed from early interrogations of catechumens (persons receiving instructions in order to be baptized) by the bishop. An example of such interrogations used in Rome about 200 has been preserved in the *Apostolic Tradition* of Hippolytus. The bishop would ask, "Dost thou believe in God the Father almighty?" and so forth through the major Christian beliefs. Stated affirmatively, these statements became a creed; such creeds were known as baptismal creeds.

The present text of the Apostles' Creed is similar to the baptismal creed used in the church in Rome in the 3rd and 4th centuries. It reached its final form in southwestern France in the late 6th or early 7th century. Gradually it replaced other baptismal creeds and was acknowledged as the official statement of faith of the entire Catholic church in the West by the time that Innocent III was pope (1198-1216).

The accepted Latin version reads as follows: Credo in Deum Patrem omnipotentem; Creatorem caeli et terrae. Et in Jesum Christum, Filium ejus unicum, Dominum nostrum; qui conceptus est de Spiritu Sancto, natus ex Maria virgine; passus sub Pontio Pilato, crucifixus, mortuus, et sepultus; descendit ad inferna; tertia die resurrexit a mortuis; ascendit ad caelos; sedet ad dexteram Dei Patris omnipotentis; inde venturus (est) judicare vivos et mortuos. Credo in Spiritum Sanctum; sanctam ecclesiam catholicam; sanctorum communionem; remissionem peccatorum; carnis resurrectionem; vitam aeternam. Amen.

A modern English version (as used in the Roman Catholic church) is the following:

I [We] believe in God, the Father almighty, creator of heaven and earth.

I [We] believe in Jesus Christ, his only Son, our Lord.

He was conceived by the power of the Holy Spirit and born of the Virgin Mary.

He suffered under Pontius Pilate, was crucified, died, and was buried.

He descended to the dead.

On the third day he rose again.

He ascended into heaven,

and is seated at the right hand of the Father.

He will come again to judge the living and the dead.

I [We] believe in the Holy Spirit, the holy Catholic Church, the communion of saints, the forgiveness of sins, the resurrection of the body, and the life everlasting. Amen.

Apostolic, Latin APOSTOLICUS, plural APOSTOLICI, member of any of the various Christian sects that sought to reestablish the life and discipline of the primitive church by a literal observance of the precepts of continence and poverty.

The earliest Apostolics (known also as Apotactici, meaning "abstinents") appeared in Anatolia about the 3rd century. They were extremely austere and renounced property and marriage. In the 12th century certain groups of heretical itinerant preachers called Apostolics were found in various centres of France, Flanders, and the Rhineland. This movement seems to have developed from a dualistic heretical current that entered Italy and France from the East during the 11th century. The wealth and worldliness of the Western church at that time encouraged the movement's growth. These groups condemned marriage, the eating of meat, and infant baptism; and they harshly criticized the church and denied priestly power.

About 1260 a religious sect known as the Apostolic Brethren was founded at Parma, Italy, by Gerard Segarelli, an uncultured workman, to restore what he considered the apostolic way of life. His emphasis on repentance and poverty reflected ideas propagated by Joachim of Fiore, a 12th-century mystic. In 1286 Pope Honorius IV ordered the eccentric sect to conform to an approved rule of life, and in 1290 Pope Nicholas IV issued a bull of condemnation; but the sect continued to spread. In 1294 four of the Apostolics were burned at the stake, and Segarelli met a similar fate in 1300. Thereafter, under the leadership of Fra Dolcino, the sect became openly heretical and anticlerical. Its power was finally broken when Dolcino was burned as a heretic in 1307.

During the Protestant Reformation many of the doctrines of the various Apostolics were espoused by the Anabaptists.

Apostolic Constitutions, formally ORDINANCES OF THE HOLY APOSTLES THROUGH CLEMENT, largest collection of ecclesiastical law that has survived from early Christianity. The full title suggests that these regulations were drawn up by the Apostles and transmitted to the church by Clement of Rome. In modern times it is generally accepted that the constitutions were actually written in Syria about AD 380 and that they were the work of one compiler, probably an Arian (one who believes that Christ, the Son of God, is not divine but rather a created being).

The work consists of eight books. The first six are an adaptation of the *Didascalia Apostolorum*, written in Syria about AD 250. They deal with Christian ethics, the duties of the clergy, the eucharistic liturgy, and various church problems and rituals.

Book 7 contains a paraphrase and enlargement of the *Didachē* (*Teaching of the Twelve Apostles*) and a Jewish collection of prayers and liturgical material, including the *Gloria in excelsis* as the liturgical morning prayer.

In book 8, the first two chapters seem to be based on a lost work of Hippolytus of Rome, *Concerning Spiritual Gifts*. Chapters 3-22 apparently are based on Hippolytus' *Apostolic Tradition* (formerly called *Egyptian Church Order*) and contain an elaborate description of the Antiochene liturgy, including the so-called Clementine liturgy. This is a valuable source for the history of the mass.

Chapters 28-46 of book 8 contain a series of canons, and chapter 47 comprises the so-called *Apostolic Canons*, a collection of 85 canons derived in part from the preceding

constitutions and in part from the canons of the councils of Antioch (341) and Laodicea (c. 360). It includes a list of biblical books that omits the Revelation to John but places the *Apostolic Constitutions* and the two letters of Clement in the canon of Scripture.

apostolic delegate, Vatican representative with no diplomatic status and hence no power to deal with civil governments. His relations are with the ecclesiastical hierarchy of a country that maintains no diplomatic relations with the Holy See. An apostolic delegate may not interfere with the exercise of the local bishops' authority in their own jurisdictions. He concerns himself with church conditions in a region, gathering and channeling all relevant information to and from the Holy See.

Apostolic Father, any of the Greek Christian writers, several unknown, who were authors of early Christian works dating primarily from the late 1st and early 2nd centuries. Their works are the principal source for information about Christianity during the two or three generations following the Apostles. They were originally called apostolic men (Apostolici). The name Apostolic Fathers was first applied in the 6th century, after the conception of the authority of the Fathers had been developed. The name did not come into common use, however, until the 17th century.

These writers include Clement of Rome, Ignatius, Polycarp, Hermas, Barnabas, Papias, and the anonymous authors of the *Didachē* (*Teaching of the Twelve Apostles*), *Letter to Diognetus*, *Letter of Barnabas*, and the *Martyrdom of Polycarp*. Not everything written by the Apostolic Fathers is considered to be equally valuable theologically, but taken as a whole their writings are more valuable historically than any other Christian literature outside the New Testament. They provide a bridge between it and the more fully developed Christianity of the late 2nd century.

apostolic succession, in Christianity, the doctrine that bishops represent a direct, uninterrupted line of descent from the Apostles of Jesus Christ. According to this doctrine, bishops possess certain special powers handed down to them from the Apostles; these consist primarily of the right to confirm church members, to ordain priests, to consecrate other bishops, and to rule over the clergy and church members in their diocese (an area made up of several congregations).

The origins of the doctrine are obscure, and the New Testament records are variously interpreted. Those who accept apostolic succession as necessary for a valid ministry argue that it was necessary for Christ to establish a ministry to carry out his work and that he commissioned his Apostles to do this (Matthew 28:19-20). The Apostles in turn consecrated others to assist them and to carry on the work. Supporters of the doctrine also argue that evidence indicates that the doctrine was accepted in the very early church. About AD 95 Clement, bishop of Rome, in his letter to the church in Corinth (*First Letter of Clement*), expressed the view that bishops succeeded the Apostles.

A number of Christian churches believe that the apostolic succession and church government based on bishops are unnecessary for a valid ministry. They argue that the New Testament gives no clear direction concerning the ministry, that various types of ministers existed in the early church, that the apostolic succession cannot be established historically, and that true succession is spiritual and doctrinal rather than ritualistic.

Roman Catholic, Eastern Orthodox, Old Catholic, Swedish Lutheran, and some other Christian churches accept the doctrine of apostolic succession and believe that the only valid ministry is based on bishops whose office has descended from the Apostles. This

does not mean, however, that each of these groups necessarily accepts the ministries of the other groups as valid. Roman Catholics, for example, generally regard the ministry of the Eastern Orthodox churches as valid but do not accept the Anglican ministry. The Anglicans, on the other hand, consider episcopacy necessary to the "well-being" but not to the "being" of the church; therefore, they not only accept the ministries of the other groups as valid but also have entered into close associations with Protestant groups that do not accept apostolic succession.

Apostolicum: see Apostles' Creed.

apostome, any protozoan of the small order Apostomatida (fewer than 50 species). Many are parasitic on marine crustaceans. The life cycle of apostomes is complex. Members of the genus *Foettingeria*, for example, multiply by fission, after which immature swimming forms called larvae, or tomites, develop, attach to crustaceans, form cysts, and develop within them. The small cytostome (mouth), when present, is often accompanied by a glandular rosette. The sparse hairlike projections (cilia) are arranged in spiral rows on the organism.

apothecaries' weight, traditional European system of weight used for the measuring and dispensing of drugs and based on the grain, scruple (20 grains), dram (3 scruples), ounce (8 drams), and pound (12 ounces). The apothecaries' grain is equal to the troy and avoirdupois grains and represents $\frac{1}{5,760}$ part of the troy and apothecaries' pound and $\frac{1}{7,000}$ part of the avoirdupois pound. One apothecaries' pound equals approximately 0.82 avoirdupois pound and 0.37 kilogram.

Apothecaries' weight was used officially in both the United States and Great Britain until 1858. In that year, under the authority of the Medical Act, Great Britain adopted the avoirdupois system for dispensing medicines. Apothecaries' weight is still common in the United States. In recent years, however, the metric system has gained in use for dispensing medicines.

apotheosis, elevation to the status of a god. The term (from Greek *apothéoun*, "to make a god," "to deify") implies a polytheistic conception of gods while it recognizes that some individuals cross the dividing line between gods and men.

The ancient Greek religion was especially disposed to belief in heroes and demigods. Worship after death of historical persons or worship of the living as true deities occurred sporadically even before the conquests of Alexander the Great brought Greek life into contact with Oriental traditions. Ancient monarchies often enlisted polytheistic conceptions of divine or semidivine individuals in support of the dynasties. Ancestor worship, or reverence for the dead, was another factor, as was also mere flattery.

The corresponding Latin term is *consecratio*. The Romans, up to the end of the republic, had accepted only one official apotheosis, the god Quirinus having been identified with Romulus. The emperor Augustus, however, broke with this tradition and had Julius Caesar recognized as a god; Julius Caesar thus became the first representative of a new class of deities proper. The tradition established by Augustus was steadily followed and was extended to some women of the imperial family and even to imperial favourites. The practice of worshiping an emperor during his lifetime, except as the worship of his genius, was in general confined to the provinces. Apotheosis, after his death, being in the hands of the Senate, did not at once cease, even when Christianity was officially adopted. The most significant part of the ceremonies attendant on an imperial apotheosis was the liberation of an imperial apotheosis was the liberation of an eagle, which was supposed to bear the emperor's soul to heaven.

apotropaic eye, a painting of an eye or eyes used as a symbol to ward off evil, appearing most commonly on Greek black-figured drinking vessels called kylikes ("eye cups"), from the 6th century BC. The exaggeratedly large eye on these cups may have been thought

Chalcidian black-figured kylix decorated with apotropaic eyes, attributed to the Phineus Painter, c. 520 BC; in the Metropolitan Museum of Art, New York City

to prevent dangerous spirits from entering the mouth with the wine.

Appalachian Highlands, the regions of the Ridge and Valley, Blue Ridge, Piedmont (*qq.v.*), and Appalachian Plateau in the eastern United States.

Appalachian Mountains, also called APALACHIANS, great highland system of eastern North America, extending for almost 2,000 miles (3,200 km) from the Canadian province of Newfoundland through the eastern United States southward to central Alabama. They form a natural barrier between the eastern seaboard and the vast lowlands of the continental interior. As a result, they have played a vital role in the settlement and development of the continent.

A brief treatment of the Appalachian Mountains follows. For full treatment, see MACROPAEDIA: North America.

The system may be divided into three large regions: northern, central, and southern Appalachia. The northern region includes such mountains as the Shickshocks and the Notre Dame ranges in Quebec; the Long Range in Newfoundland; Mount Katahdin in Maine; the White Mountains of New Hampshire; and Vermont's Green Mountains, which become the Berkshires in Massachusetts, Connecticut, and eastern New York. New York's Catskills and the beginnings of the Blue Ridge range in southern Pennsylvania and the Alleghenies, which rise in New York and cover parts of western Pennsylvania, western Maryland, and eastern Ohio, are in central Appalachia. The southern region includes portions of the Alleghenies of West Virginia and Virginia; the Blue Ridge range of Virginia, western North Carolina, and parts of South Carolina and Georgia; the Unakas in Virginia, Tennessee, and North Carolina; and the Cumberland Mountains, extending from eastern Kentucky south to northern Alabama.

The highest elevations in the Appalachians are in the northern division in the White Mountains and in the southern region, where peaks of the North Carolina Black Mountains and the Great Smoky Mountains rise above 6,000 feet (1,800 m) and where the entire system reaches its highest summit on Mount Mitchell (6,684 feet [2,037 m]). A distinctive feature of the mountain system is the Great Appalachian Valley. It includes the St. Lawrence River valley in Canada and the Kitatinny, Cumberland, Shenandoah, and Tennessee valleys in the United States. A non-commercial motor route runs 469 miles (755 km) from the Shenandoah Valley in Virginia to the Great Smoky Mountains National Park, and the Appalachian National Scenic Trail is a 2,100-mile (3,400-kilometre) footpath.

The Appalachians are among the oldest mountains on Earth, consisting mostly of crystalline rocks and Paleozoic sediments. The

entire Appalachian system is laced with an intricate network of springs, streams, waterfalls, and rivers, especially in the southern Appalachians. Generally, northeast of the New River in Virginia, the major Appalachian rivers flow into the Atlantic Ocean, while southwest of the New the rivers drain into the Ohio River valley. The most extensive broad-leaved deciduous forests in the world flourish in southern Appalachia, and a mix of conifers and northern hardwoods predominate in the north. The western slopes of the Great Smokies receive an annual rainfall as high as 90 inches (2,286 mm), producing trees that have reached record maximum heights and diameters.

Important lumber and pulp, coal, iron-ore, salt, granite, and marble industries operate in the region but have had deleterious effects on the environment. Despite the early arrival of the lumber industry and coal mining, some areas remained isolated until early in the 20th century, notably those mountain areas of southern Appalachia where rough terrain hindered road construction. Consequently, Southern highlanders developed a folk culture characterized by distinctive handicrafts, ballads, and folklore. The Appalachians combine a heritage of natural beauty and a distinctive regional culture with contemporary problems of economic deprivation and environmental deterioration.

Appalachian National Scenic Trail, mountain footpath for hikers extending from northeast to southwest some 2,100 miles (3,400 km), from Mount Katahdin, Maine, U.S., to Springer Mountain, Georgia, along the crest of the Appalachian Mountains. The trail passes through 14 states, 8 national forests, and 2 national parks. Hikers are responsible for the upkeep of the primitive shelters and trailside campsites, located 7 to 8 miles apart. Originally established by hiking enthusiasts in the 1920s and '30s, the trail became one of the two initial units of the National Trail System established by the U.S. Congress in 1968. Most of the trail runs through public lands (*e.g.*, national parks), but short stretches of it still traverse privately owned tracts.

Appalachian orogenic belt, a linear trough in the Earth's crust that extends for more than 3,000 km (1,860 miles) along the eastern margin of North America from Alabama in the southern United States to Newfoundland, Canada, in the north. The geosynclinal theory of mountain building was first worked out in the Appalachians by James Dana and James Hall in the late 19th century; today a plate tectonic theory is invoked. The earliest Appalachian sediments were deposited near the start of the Cambrian Period (570 million

years ago) on the shores of the opening Iapetus Ocean. Subduction of the Iapetus led to its destruction and the collision of different continental blocks and island arcs. Those collisions gave rise to three Appalachian orogenies: Taconic in the Middle Ordovician (about 460 million years ago); Acadian in the Early to Late Devonian (at 390 to 370 million years); and Alleghenian in the Late Carboniferous to Permian (300 to 250 million years ago). The effects of these orogenies decrease eastward across the orogenic belt, demonstrating that it was formed by the progressive eastward addition of arcs and continental fragments to the continental margin of North America. The Appalachian belt continues to the east in the form of the Caledonian and Hercynian orogenic belts in western Europe. The Alleghenian orogeny led to the formation in the Permian Period (286 to 245 million years ago) of the Pangaea supercontinent. Geophysical seismic studies show that the southern Appalachian Mountains comprising the Ridge and Valley region, the Blue Ridge Mountains, and the Piedmont region belong to a crustal slab some 6–15 km (3.7 to 9.3 miles) thick that has been thrust 260 km (162 miles) westwards over the former continental margin.

Appaloosa, colour breed of horse popular in the United States. The breed is said to have descended in the Nez Percé Indian territory of North America from wild mustangs, which in turn descended from Spanish horses brought in by explorers. The name derives from the Palouse River of Idaho and Washington. The Appaloosa has several distinctive colour patterns and all of the regular coat colours. Some Appaloosas have a solid colour except for a white patch over the hips, interspersed with

Appaloosa
Sally Anne Thompson

small, round spots of the same colour as the body. Others have a basic solid colour with white dots over the entire body or are white with coloured dots. They are 15 to 15.3 hands (about 60 to 63 inches, or 152 to 160 cm) tall and weigh from 1,000 to 1,100 pounds (450 to 500 kg). Appaloosas are of light but sturdy conformation. The Appaloosa Horse Club was organized in 1938.

appanage, in France, primarily before the Revolution, the provision of lands within the royal domain, or in some cases of pensions, to the children of the royal family so that they might live in a style corresponding to their position in society. Appanages were established to provide for the younger brothers and sisters of the king but were also given to an heir to the throne before his succession, at which time the land was reannexed to the crown. Appanages were most prevalent from the 13th to the 16th century.

Appanages raised certain problems for the crown, largely because of the personal relationship that existed between the holder and

the king. At the same time, however, they afforded an opportunity for the growth and development of royal administration within the areas held by appanage, facilitating their ultimate reunion with the crown. After the 14th century, except in a few special instances, women ceased to receive land appanage but received pensions instead. In 1566 the Ordinance of Moulins established the principle of the inalienability of the domain, although during the Wars of Religion of the next 30 years it was not always strictly adhered to. With the growth of the absolute power of the monarch during the 17th century, appanages ceased to be much of a problem. Early in the French Revolution (1790), appanages were reduced to pensions or rents and then completely abolished. They were reestablished in 1810 according to the provisions of 1790 and finally abolished in 1832.

appeal, the resort to a higher court to review the decision of a lower court, or to any court to review the order of an administrative agency. Every legal system provides, at least in form, for some type of appeal.

The concept of appeal requires the existence of a judicial hierarchy, although it is possible for a court to review its own judgments. A typical hierarchy will include trial courts of limited or special jurisdiction, often called magistrates' courts, justices of the peace, small-claims courts, municipal courts, or police courts; trial courts of general jurisdiction that usually carry the name of district court, circuit court, or superior court; and a court of appellate jurisdiction, which may be the ultimate supreme court of a system. Some countries introduce an intermediate appellate court, called the court of appeals, between the trial court level and the court of ultimate appeal. Usually, each court in the hierarchy is subject to review only by the court immediately above it. Frequently, however, an intermediate step may be omitted because the importance or immediacy of the problem calls for direct review of the trial court by the highest appellate tribunal.

In some countries different courts serve as the highest appeals court according to the types of cases and judicial problems. In France the Cour de Cassation (the supreme court) hears appeals on the interpretation of the law, whereas the court of appeal retries cases on the issue of fact. The Conseil d'État, on the other hand, hears appeals both on facts and on the interpretation of law from a separate system of administrative courts. Constitutional questions, when dealt with at all, are handled by a constitutional council that is both legislative and judicial.

In Germany the Bundesgerichtshof (Federal Court of Justice) is concerned primarily with a unified interpretation of the law, and there is a separate constitutional court (Bundesverfassungsgericht) to deal with constitutional questions. The court of appeals (Oberlandesgericht) retries cases both on issues of law and of fact in civil matters and on issues of law only in criminal matters. The Supreme Court of the United States hears appeals on fact, interpretation, and constitutional cases, but, except for cases that have an important effect on the public interest, appeal stops with the Federal Circuit Court of Appeals. In England appeals on matters of fact in some instances go to different courts than do those on matters of law. In some cases, appeals to the House of Lords, the final court of appeal, are prohibited. The Supreme Court of Japan serves as final-appeals court on questions of fact and law and on constitutional compatibility.

As a practical as well as a legal matter, only the party aggrieved by an order or judgment is entitled to seek a review of it in the appellate court. Neither an outsider nor the party who had prevailed in the case is permitted to seek a review of the decision by a higher court.

When, however, persons not originally parties to the action have been permitted to intervene or have been represented by others, as in class actions, they generally have the same rights of appeal as have the original parties. There are few jurisdictions in which an appeal on a verdict of acquittal is allowed.

Orders and judgments of trial courts may be divided into two categories for the purposes of appeal: final and interlocutory. A final judgment is one that brings an end to litigation and leaves nothing but the execution of the judgment. In the course of a trial, however, a court is required to enter decisions that settle only subsidiary questions or some but not all of the ultimate issues. These decisions are regarded as interlocutory decrees. Although all jurisdictions sanction appeals from final judgments, appeals from interlocutory decrees are far less widespread.

Basically, the appeal serves two functions. Its first and primary function is to assure the litigants that justice under law has been done in the resolution of a specific controversy. The second function is the promulgation of rules of decision that will be binding on all lower courts within a judicial system, thus assuring uniformity of treatment and some measure of certainty and guidance to those whose actions bring them within the scope of the rule.

Appeal, Court of, in England and Wales, the highest court below the House of Lords, which sits as the final court of appeal in both criminal and civil matters.

The court is divided into two divisions: the Civil Division and the Criminal Division. The Civil Division takes cases on appeal from the High Court of Justice and the county courts. Four members of its judiciary are considered *ex officio*: the lord chancellor (who is head of the Chancery Division of the High Court), the lord chief justice (who presides over the Queen's [or King's] Bench Division of the High Court), the president of the Family Division of the High Court, and the master of rolls. There are also 14 regular members who are called the lord justices of appeal.

The Criminal Division consists of a president (either the lord chief justice or a lord justice of appeal) and other High Court judges hearing the cases as "ordinary" members. Appeals may come from the High Court immediately below or from the Crown Court.

Appeals against a sentence or conviction may be brought on a point of law. Occasionally, with the permission of either the trial judge or the Court of Appeal, a question of fact may be entered, or a question of *both* fact and law may be permitted as the basis for an appeal.

The Court of Appeal may uphold the decision of the lower court, reverse it, or change the sentence. (However, the new sentence may not be more severe than the original.) Although the court rarely orders a retrial, it may do so in the interests of justice. The Court of Appeal may also act as an advisory body for the attorney general.

If the House of Lords refuses to hear an appeal from a decision of the Court of Appeal, that decision is final.

Appel, Karel (b. April 25, 1921, Amsterdam, Neth.), Dutch painter of turbulent, colourful, semiabstract compositions, a cofounder (1948–49) of the Cobra group of northern European Expressionists.

Appel attended the Royal Academy of Fine Arts, Amsterdam (1940–43), and helped found the "Reflex" group, the Dutch precursor of Cobra, in 1948. He moved to Paris in 1950 and, finally, by the 1960s, had settled in New York City. Partly in reaction against what they perceived as the sterile academicism of the de Stijl movement, the Cobra artists assimilated a variety of more impulsive influences, including folk art, children's art, and *l'art brut* ("raw art") of Jean Dubuffet. They exploited the spontaneity and intensity of the contemporary

American Action painting while maintaining a degree of representation. Appel's style is characterized by thick layering of pigment, violent brushwork, and a crude, reductive figuration.

He first visited the United States in 1957, where he painted portraits of prominent jazz musicians, including Miles Davis and Dizzy Gillespie. His public works include a mural in the UNESCO building in Paris. His figurative sculptures in wood and metal share with the paintings a brutal, imaginative expressionism.

appendicitis, inflammation of the appendix (*q.v.*).

appendicularian: see larvacean.

appendix, formally VERMIFORM APPENDIX, in anatomy, a vestigial hollow tube attached to the cecum; the blockage of the appendix can result in appendicitis.

The appendix is a narrow, muscular tube that is closed at one end and is attached to and opens into the cecum at its other end.

Appendix

(The cecum is the pouchlike beginning of the large intestine; the small intestine empties into the cecum.) The appendix does not serve any useful purpose as a digestive organ in humans, and it is believed to be gradually disappearing in the human species over evolutionary time. (The vermiform appendix exists only in human beings and higher apes, but an appendix-like structure does exist in wombats, civets, rodents, and a few other lower animals.)

The appendix is usually 8 to 10 cm (3 to 4 inches) long and less than 1.3 cm (0.5 inch) wide. The cavity of the appendix is much narrower where it joins the cecum than it is at its closed end. The appendix has muscular walls that are ordinarily capable of expelling into the cecum the mucous secretions of the appendiceal walls or any of the intestinal contents that have worked their way into the structure. If anything blocks the opening of the appendix, or prevents it from expelling its contents into the cecum, appendicitis may occur. The most common obstruction in the opening is a fecolith, a hardened piece of fecal matter. Swelling of the lining of the appendiceal walls themselves can also block the opening. When the appendix is prevented from emptying itself, a series of events occurs. Fluids and its own mucous secretions collect in the appendix, leading to edema, swelling, and the distention of the organ. As the distention increases, the blood vessels of the appendix become closed off, causing the necrosis (death) of appendiceal tissue. Meanwhile, the bacteria normally found in this part of the intestine begin to propagate in the closed-off pocket, worsening the inflammation. The appendix, weakened by necrosis and subject to increasing pressure from within by the distention, may burst, spilling its contents into the abdominal cavity and infecting the membranes that line the cavity and cover the abdominal organs (see peritonitis). Fortunately peritonitis is usually prevented by

the protective mechanisms of the body. The omentum, a sheet of fatty tissue, often wraps itself about the inflamed appendix, and an exudate that normally develops in the areas of inflammation behaves like glue and seals off the appendix from the surrounding peritoneal cavity.

A person experiencing an attack of appendicitis may feel pain all over the abdomen or only in the upper abdomen or about the navel. This pain is usually not very severe. After one to six hours or more the pain may become localized to the right lower abdomen. Nausea and vomiting may develop some time after the onset of the pain. Fever is usually present but is seldom high in the early phases of the attack. The patient's leukocytes (white blood cells) are usually increased from a normal count of 5,000–10,000 in an adult to an abnormal count of 12,000–20,000; this phenomenon can be caused by many other acute inflammatory conditions that occur in the abdomen.

In a person with a normally sited appendix, the pain of appendicitis is situated at a point between the navel and the front edge of the right hipbone. But many people have their appendix lying in an abnormal position, and they thus may feel the pain of an appendicitis attack in a different or misleading location, making their symptoms difficult to distinguish from the abdominal pain caused by a variety of other diseases. Careful diagnostic examination by a physician can usually determine if acute appendicitis is indeed causing a patient's abdominal pain.

The basic treatment of appendicitis is the surgical removal of the appendix in a minor operation called an appendectomy. The operation itself requires little more than a half hour to carry out under anesthesia and produces relatively little postoperative discomfort. If a diagnosis of acute appendicitis cannot immediately be made with reasonable certainty, it is now customary to wait and observe the patient's symptoms for a period from 10 to 24 hours so that a definitive diagnosis can be made. This wait does slightly increase the risk that the appendix will rupture and peritonitis set in, so the patient is kept under careful medical surveillance at this time.

Appendix on the Papacy (1537): see *Treatise on the Power and Primacy of the Pope*.

Appenzell, canton, northeastern Switzerland, consisting of two autonomous half cantons. Appenzell is entirely surrounded by present-day Sankt Gallen canton. It was first mentioned by name in 1071 as *Abbatis Cella*, in reference to its rulers, the abbots (later prince abbots) of Sankt Gallen. As early as 1377, however, this portion of the abbots' domains formed an alliance with the Swabian free imperial cities and adopted a constitution of its own. The region defended itself against the abbots in the Appenzell War of 1403–10 and in 1411 was placed under the "protection" of the Swiss Confederation, of which it became a member in 1513. Religious differences after the Counter-Reformation led to the division of the canton in 1597 into the independent half cantons of Appenzell Inner-Rhoden (predominantly Roman Catholic) and Appenzell Ausser-Rhoden (predominantly Protestant). These names refer simply to the inner or outer portions, or districts, of Appenzell itself; *Rhoden* in its singular form is said originally to have meant a clearing.

Appenzell, capital of the half canton of Appenzell Inner-Rhoden, northeastern Switzerland, in the Sitter Valley, south of Sankt Gallen. Originally a possession of the abbey of Sankt Gallen, it was the traditional capital of the Appenzell region and became the capital of Inner-Rhoden after the canton was divided in 1597. Notable landmarks include an ancient chapel of the abbots of Sankt Gallen; a mod-

ern church with a late Gothic choir; the town hall (1561–63); the 16th-century castle housing a historical museum; and two Capuchin convents. Two important annual events are the Corpus Christi procession and the meeting of the *Landsgemeinde* (or open-air cantonal "parliament"—actually a cantonal legislative meeting of all concerned citizens, a nearly unique manifestation of "pure democracy"). Pastoral occupations, embroidery, and the manufacture of textiles and furniture are the principal economic activities. The population is German speaking and Roman Catholic. Pop. (1998 est.) 5,594.

Appenzell Ausser-Rhoden (German), French APPENZELL RHODES-EXTÉRIEURES, English APPENZELL OUTER RHODES, half canton, comprising the northern and western parts of former Appenzell canton, northeastern Switzerland. It has an area of 94 square miles (243 square km) and was divided for religious reasons from Appenzell Inner-Rhoden half canton in 1597. Its constitution dates from 1908, and its capital and largest town is Herisau (*q.v.*), although the *Landsgemeinde* (open-air general legislative meeting) meets alternately at nearby Hundwil and at Trogen. Cotton goods, muslins, and embroideries are manufactured. The population is German speaking and predominantly Protestant. Pop. (1998 est.) 53,816.

Appenzell Inner-Rhoden (German), French APPENZELL RHODES-INTÉRIEURES, English APPENZELL INNER RHODES, half canton, comprising the southern part of former Appenzell canton, northeastern Switzerland, at the north foot of the Säntis Peak. It has an area of 67 square miles (172 square km) and was divided from Appenzell Ausser-Rhoden half canton in 1597 for religious reasons. Its constitution dates from 1872, and its capital is Appenzell (*q.v.*). Although mountainous, the canton is largely pastoral with extensive cattle breeding and dairying. Hand embroidery is also important. The population is German speaking and almost entirely Roman Catholic. Pop. (1998 est.) 14,873.

Appert, Nicolas (-François) (b. c. 1750, Châlons-sur-Marne, Fr.—d. June 3, 1841, Massy, near Paris), French chef, confectioner, and distiller who invented the method of preserving food by enclosing it in hermetically sealed containers. Inspired by the French Directory's offer of a prize for a way to conserve food for transport, Appert began a 14-year period of experimentation in 1795. Using

Appert, lithograph by Guffanti
H. Roger-Viollet

corcked-glass containers reinforced with wire and sealing wax and kept in boiling water for varying lengths of time, he preserved soups, fruits, vegetables, juices, dairy products, marmalades, jellies, and syrups. A 12,000-franc award in 1810 specified that he publish his findings, which appeared that year as *L'Art de conserver, pendant plusieurs années, toutes les substances animales et végétales* (*The Art*

of *Preserving All Kinds of Animal and Vegetable Substances for Several Years*). He used the money to establish the first commercial cannery, the House of Appert, at Massy, which operated from 1812 until 1933. Appert also developed the bouillon tablet, devised a nonacid gelatin-extraction method, and perfected an autoclave.

Appia, Adolphe (b. Sept. 1, 1862, Geneva—d. Feb. 29, 1928, Nyon, Switz.), Swiss stage designer whose theories, especially on the interpretive use of lighting, helped bring a new realism and creativity to 20th-century theatrical production.

Although his early training was in music, Appia studied theatre in Dresden and Vienna from the age of 26. In 1891 he propounded his revolutionary theories of theatrical production. Four years later he published *La Mise en scène du drame Wagnérien* (1895; "The Staging of the Wagnerian Drama"), a collection of stage and lighting plans for 18 of Wagner's operas that clarified the function of stage lighting and enumerated in detail practical suggestions for the application of his theories. In *Die Musik und die Inszenierung* (1899; "Music and Staging"), Appia established a hierarchy of ideas for achieving his aims: (1) a three-dimensional setting rather than a flat, dead, painted backdrop as a proper background to display the movement of the living actors; (2) lighting that unifies actors and setting into an artistic whole, evoking an emotional response from the audience; (3) the interpretive value of mobile and colourful lighting, as a visual counterpart of the music; and (4) lighting that spotlights the actors and highlights areas of action. He expanded his theories in a second book, *L'Oeuvre d'art vivant* (1921; "The Living Work of Art").

Appia designed sets in Germany, France, Italy, and Switzerland. He collaborated with Émile Jaques-Dalcroze on numerous experimental theatre and dance productions. He also designed sets for La Scala opera house in Milan and for the opera house at Basel. A biography of him is Walther Volbach's *Adolphe Appia, Prophet of the Modern Theatre* (1968).

Appiah, Kwame Anthony, in full KWAME ANTHONY AKROMA-AMPIM KUSI APPIAH (b. May 8, 1954, London), British-born American philosopher, novelist, and scholar of African and African American studies.

Appiah's father, Joseph Appiah, was a Ghanaian-born barrister; his maternal grandfather was the British statesman Sir Stafford Cripps. Appiah attended Clare College at the University of Cambridge, where he earned a Ph.D. in philosophy in 1982. He taught philosophy, African studies, and African American studies at various universities during the 1980s and '90s. He joined the University Center for Human Values at Princeton University in 2002.

Appiah's *In My Father's House: Africa in the Philosophy of Culture* (1992) is a philosophical exploration of the nature of African identity. In *Color Conscious: The Political Morality of Race* (1996; with Amy Guttmann), Appiah argued that the importance of race as a component of individual identity has been overestimated. *The Ethics of Identity* (2005) critically examined the various notions around which "group" identities have been defined and considered how group identity may both contribute to and constrain individual freedom.

Appian OF ALEXANDRIA (fl. 2nd century AD), Greek historian of the conquests by Rome from the republican period into the 2nd century AD.

Appian held public office in Alexandria, where he witnessed the Jewish insurrection in

AD 116. After gaining Roman citizenship he went to Rome, practiced as a lawyer, and at an advanced age became a procurator.

In addition to a lost autobiography, Appian wrote in Greek a *Romaica*, or history of Rome, in 24 books, arranged ethnographically according to the peoples (and their rulers) conquered by the Romans. The books that survive in complete form deal with Spain, Carthage, Illyria, Syria, Hannibal, Mithradates, and the Roman civil wars from the Gracchi onward. Extracts from other books survive in Byzantine compilations and elsewhere.

Appian wrote in a Greek that was no longer classical. Not himself an able historian, he nevertheless preserved much information of value by his transmission of earlier sources. His first book on the civil wars, dealing with the period from Tiberius Gracchus (tribune 133 BC) to Sulla (d. 78 BC), is a major historical source.

Appian Way, Latin VIA APPIA, the first and most famous of the ancient Roman roads, running from Rome to Campania and southern Italy. (See Roman road system.) The Appian Way was begun in 312 BC by the censor Appius Claudius Caecus. At first it ran only 132 miles (212 km) from Rome south-southeastward to ancient Capua, in Campania, but by about 244 BC it had been extended another 230 miles (370 km) southeastward to reach the port of Brundisium (Brindisi), situated in the "heel" of Italy and lying along the Adriatic Sea.

From Rome southward the Appian Way's course was almost straight until it reached Terracina (Terracina) on the Tyrrhenian Sea. The road then turned inland to the southeast to reach Capua. From Capua it ran east to Beneventum (Benevento) and then southeastward again to reach the port of Tarentum (Taranto). It then ran east for a short distance to terminate at Brundisium.

The Appian Way was celebrated by Horace and Statius, who called it *longarum regina viarum*, or "queen of long-distance roads." As the main highway to the seaports of southeastern Italy, and thus to Greece and the eastern Mediterranean, the Appian Way was so important that during the empire it was administered by a curator of praetorian rank. The road averaged 20 feet (6 m) in width and was slightly convex in surface in order to facilitate drainage. The road's foundation was of heavy stone blocks cemented together with lime mortar; over these were laid polygonal blocks of lava that were smoothly and expertly fitted together. The lava blocks formed a good traveling surface, and one that proved to have extraordinary durability over the centuries. The first few miles outside Rome are flanked by a striking series of monuments, and there are also milestones and other inscriptions along the remains of the road.

Appius (ancient Roman personal name, or praenomen): see under gens or family name or honorific (e.g., under Claudius for Appius Claudius Caecus).

apple, fruit of the genus *Malus* (about 25 species) belonging to the family Rosaceae, the most widely cultivated tree fruit. The apple is one of the pome (fleshy) fruits, in which the ripened ovary and surrounding tissue both become fleshy and edible. The apple flower of most varieties requires cross-pollination for fertilization. Apples at harvest, though varying widely in size, shape, colour, and acidity, depending upon cultures (variety) and environmental character, are, nevertheless, usually roundish, 50–100 mm (2–4 inches) in diameter, and some shade of red or yellow in colour.

Apple varieties, of which there are thousands, fall into three broad classes: (1) cider varieties; (2) cooking varieties; and (3) dessert varieties, which differ widely but tend to emphasize colour, size, aroma, smoothness, and perhaps

Apples (*Malus*)

Grant Heilman—EB Inc

crispness and tang. Many varieties are relatively high in sugar, only mildly acidic, and very low in tannin. The apple is eaten fresh or cooked in a variety of ways. It is frequently used as a pastry filling, the apple pie being perhaps the archetypal American dessert. Especially in Europe, fried apples characteristically accompany certain dishes of sausage or pork.

Malus species are native to the temperate zones of both hemispheres. Apples were eaten by the earliest Europeans; improved selections had been made and varieties were recognized more than 2,000 years ago. Hundreds of varieties were recognized in Europe before the settlement of the Americas. As the wave of settlement moved across North America, it was accompanied by the distribution of seedling apple varieties, perhaps by Indians and trappers, certainly by itinerants who became local legendary figures, the most prominent being Johnny Appleseed (John Chapman), a professional nurseryman who planted apple trees extensively in Ohio and Indiana.

Since the apple requires a considerable period of dormancy, it thrives in areas having a distinct winter period, generally from latitude 30° to 60°, both north and south. Northward, apple growing is limited by low winter temperatures and a short growing season.

The soils in which apple trees grow must be well-drained; fertilizers can be used if fertility is not high enough. Rolling hilltops or the sloping sides of hills are preferred because they provide "air drainage," allowing the colder, heavier air to drain away to the valley below during frosty spring nights, when blossoms or young fruit would be destroyed by much exposure to cold.

Scions of desired varieties are commonly grafted to hardy nursery seedlings of about 18 months of age; orchard planting follows one or two years later. Management during the six to eight years before appreciable apple production is reached may consist of little more than protection from competing vegetation and pests. Careful attention to pruning is required, however, especially during the first five years, so that the main scaffold branches will be well-distributed along the trunk and so that weak crotches will not develop that can break under heavy fruit loads. With mature trees, a rigorous spraying regime must be followed to protect against insect pests and possibly to delay spring development, to thin young fruit, and to hold the autumn drop of ripening fruit to a minimum.

Apple varieties that ripen during late summer are generally of poor quality for storage. Varieties that ripen in late autumn may be stored for as long as one year, however. For long holding, temperatures only slightly above the freezing point of the fruit are generally desirable. Apples may also be stored in inert gases or in controlled atmospheres.

The world crop of apples averages about 44,000,000 metric tons a year. Of the American crop, more than half is normally used as fresh fruit. About one-fifth is used for vinegar, juice, jelly, and apple butter. About one-sixth is canned as pie stock and applesauce.

In Europe a larger fraction of the crop goes for cider, wine, and brandy. Of the total world production, one-fourth goes for cider. The largest producers of apples are the United States, China, France, Italy, and Turkey.

Apples provide vitamins A and C, are high in carbohydrates, and are an excellent source of dietary fibre.

Apple Computer, Inc., American manufacturer of personal computers, computer peripherals, and computer software. It was the first successful personal computer company and the popularizer of the graphical user interface. Headquarters are in Cupertino, California.

In 1976 Stephen Wozniak, a 26-year-old engineer at the Hewlett-Packard Company, designed an inexpensive personal computer based on the recently invented microprocessor. He and Steve Jobs (*q.v.*), 21 years old, then formed Apple. In 1977 they introduced the Apple II, which, complete with a colour display, was an instant success. By a combination of aggressive discounts and donations, Apple established an early dominance among educational institutions. By the end of 1980 its stock market valuation was nearly \$2 billion. However, Apple soon faced competition from International Business Machines Corporation (IBM), whose own line of personal computers, the IBM PC, was introduced in 1981 and immediately became the standard in the business community.

Apple was already working, however, on computers that incorporated a new type of operating system (OS): a graphical user interface, featuring on-screen windows, a pointing device known as a mouse, and clickable icons. The Macintosh, or Mac, was released in 1984. In the wake of poor initial sales, Jobs was ousted from the company in September 1985 by chief executive officer (CEO) John Sculley. (Wozniak had left Apple in 1985 to become a teacher.)

The Mac was saved by Apple's introduction of an affordable laser printer along with Aldus Corporation's PageMaker. Together these two innovations launched the desktop publishing revolution, and the graphic arts and publishing industries quickly became the Mac's single most important market. Still, during the late 1980s, Apple's market share began to fall as successive versions of Microsoft Corporation's Windows OS (introduced in 1985) were improved and as competition led to greater innovation and lower prices.

Michael Spindler replaced Sculley in 1993. Spindler's most notable achievements as CEO were the successful migration of the Mac OS to the new PowerPC microprocessor and the initiation of a shift toward PC-compatible components. Nevertheless, Apple struggled with poor marketing projections and quality-control problems—failings that brought an end to Spindler's reign in early 1996. His successor, Gilbert Amelio, cut operating costs and reestablished quality controls, but sales sagged and losses mounted. In December 1996, in order to secure a new operating system, Apple purchased NeXT Software, Inc., the company formed by Jobs after his 1985 departure. Jobs was retained as an adviser and then, in mid-1997, was restored as the leader of the company.

Jobs streamlined what had become a confusing product line to focus on the company's traditional markets of education, publishing, and consumers, and he helped oversee the introduction of more affordable computers, notably the iMac. The iMac quickly became the all-time best-selling Mac. Nevertheless, PC-compatibles continued to outpace Mac sales, and Apple's market share soon resumed its downward spiral. In March 2001 Apple released its next-generation operating system, OS X.

apple moss (*Bartramia pomiformis*), moss of the order Bryales that has apple-shaped capsules (spore cases) and forms wide, deep cush-

ions in moist, rocky woods throughout the Northern Hemisphere. It is one of more than 100 species in the genus *Bartramia*; more than 10 are found in North America. An apple moss is usually erect, with a two-forked caudil (stem) about 6 cm (2.25 inches) tall, with rust-coloured, feltlike hairs on its lower part.

Applesed, Johnny: see Chapman, John.

Appleton, city, seat (1851) of Outagamie county, east-central Wisconsin, U.S. The city lies along the Fox River near its outflow from Lake Winnebago, 31 miles (48 km) southwest of Green Bay. The settlement of the area was encouraged by the presence of Lawrence College (chartered 1847, now a university), founded by Amos A. Lawrence of Boston, and of abundant waterpower. First called Grand Chute, the settlement was later renamed for Samuel Appleton, Lawrence's father-in-law. Milling dominated Appleton's early economy. In 1882 America's first hydroelectric power station was opened there. Foremost among the city's diversified manufactures are paper and paper-mill machinery and equipment. The Institute of Paper Chemistry (1929), affiliated with the university, has a notable library on pulp and paper as well as the Dard Hunter Paper Museum. Fox Valley Technical Institute (1967) is in Appleton. Inc. 1857. Pop. (1999 est.) city, 67,178; Appleton-Oshkosh-Neenah MSA, 348,100.

Appleton, Sir Edward Victor (b. Sept. 6, 1892, Bradford, Yorkshire, Eng.—d. April 21, 1965, Edinburgh), winner of the Nobel Prize for Physics in 1947 for his discovery of the so-called Appleton layer of the ionosphere, which is a dependable reflector of radio waves and as such is useful in communication. Other ionospheric layers reflect radio waves sporadically, depending upon temperature and time of day.

Educated at St. John's College, Cambridge, Appleton worked at the Cavendish Laboratory from 1920 until he was appointed Wheatstone professor of physics at King's College, University of London, in 1924. There he attained international repute with his research into the propagation of electromagnetic waves and the characteristics of the ionosphere. He showed that radio waves of wavelength sufficiently short to penetrate the lower region of the ionosphere are reflected by an upper region (now known as the Appleton layer, or F_2 layer). This discovery made possible more reliable long-range radio communication and aided in the development of radar.

In 1936 Appleton returned to Cambridge as Jacksonian Professor of Natural Philosophy and in 1939 became secretary of the government's Department of Scientific and Industrial Research, where he worked on radar and the atomic bomb. He was knighted in 1941 and became principal and vice-chancellor of Edinburgh University in 1949.

Appleton layer, upper layer (called F_2) of the F region (*q.v.*) of the ionosphere.

application lace, French POINT APPLIQUÉ, lace in which motifs (flowers and the like) are worked individually and then joined to a net background (whether made by machine or by

Application lace from Brussels, 1880; in the Institut Royal du Patrimoine Artistique, Brussels

By courtesy of the Institut Royal du Patrimoine Artistique, Brussels
photograph © A.C.L. Brussels

hand), in contrast to the method in which the net is worked around the solid parts of the design and the whole lace worked as a single piece without joins. In the 19th century application lace was made especially at Brussels and, in England, at Honiton. The method shortened the time required for production by employing a team of women simultaneously on the same piece of lace.

applied psychology, the use of the findings and methods of scientific psychology in solving practical problems of human and animal behaviour and experience. A more precise definition is impossible because the activities of applied psychology range from laboratory experimentation through field studies of specific utility to direct services to troubled persons.

The same intellectual streams whose confluence produced psychology as an independent discipline in the latter part of the 19th century led to the later development of an applied psychology. Francis Galton's publication in 1883 of *Inquiries Into Human Faculty* foreshadowed the measurement of individual psychological differences. In 1896 Lightner Witmer established at the University of Pennsylvania, Philadelphia, a clinic that was a forerunner of clinical psychology. Intelligence testing began with the work of Alfred Binet and Théodore Simon in the Paris schools. Group testing, legal problems, industrial efficiency, motivation, and delinquency were among other early areas of application. At the Carnegie Institute of Technology, Pittsburgh, a division of applied psychology was established as a teaching and research department in 1915. The *Journal of Applied Psychology* appeared in 1917 along with the first applied-psychology text, by H.L. Hollingsworth and A.T. Poffenberger. World Wars I and II fostered work on vocational testing, evaluation of attitudes and morale, performance under stress, propaganda and psychological warfare, rehabilitation, and counseling.

After World War II many trends in applied psychology were accentuated by the demands of the space age. Educational psychologists applied themselves to the task of early identification and discovery of talented persons, since it was recognized that trained intelligence is an important national resource. Such activities were linked with the work of counseling psychologists, who sought to help persons clarify and attain their educational, vocational, and personal goals. Concern for the optimum utilization of human resources also increased the importance of industrial and personnel psychology in business and industry. The aviation industry and the various space agencies and organizations were important in the rapid development of engineering psychology; as machines and engineering systems grew in complexity, it was necessary to study man-machine relationships. In response to concern for treatment of the mentally ill and for preventive measures against mental illness, clinical psychology showed the greatest absolute growth rate within psychology. Psychologists studied the application of automation, and in the developing countries they helped with the problems of rapid industrialization and manpower planning.

Regardless of the applied psychologist's professional focus, his job description is likely to overlap with those of other areas. The applied psychologist may or may not engage in original research and/or teach. In addition to drawing on experimental findings gleaned from psychological research, the applied psychologist utilizes information from many disciplines. The scope of the field is continually broadening as new types of problems (*e.g.*, technological) arise. Other branches of applied psychology include consumer, school, and

community psychology. Prevention and treatment of emotional problems in naturalistic settings (*i.e.*, the community) have received a great deal of attention, as have medically related questions (*e.g.*, sports psychology and the psychology of chronic illness).

Psychometrics, or the measurement and evaluation of psychological variables such as personality, aptitude, or performance, is an integral part of applied-psychology fields. For example, the clinical psychologist may be interested in measuring the traits of aggressiveness or obsessiveness; the counseling psychologist, areas of career interest or aptitude; the industrial psychologist, work effectiveness under certain conditions of lighting or office design; or the community psychologist, psychological effects of living near a nuclear power plant or radioactive waste disposal site. *See also* clinical psychology; counseling; educational psychology; industrial psychology.

appliqué, sewing technique in which fabric patches are layered on a foundation fabric, then stitched in place by hand or machine with the raw edges turned under or covered with decorative stitching. Like patchwork (piecing), it is a method of constructing or embellishing quilts. (*See* quilting.)

Eighteenth-century American quilts often combined appliquéd motifs with patchwork. Quilters cut printed motifs from expensive imported chintz and appliquéd them to plain muslin in a process known as *broderie perse* ("Persian embroidery"). It remained a favourite technique for "best quilts" until replaced toward the mid-19th century by the elaborate appliquéd patterns—wreaths, urns of flowers, sentimental and patriotic motifs—of Baltimore Album quilts.

Nineteenth-century appliquéd designs were often made in larger scale; as few as four blocks were needed for a full-sized quilt. The 20th century, especially the Depression era of the 1930s, produced its own crop of appliquéd designs such as Sunbonnet Sue and Dresden Plate, often embellished with embroidery and rendered in the pastels popular during the period. Large-scale Hawaiian appliqués feature abstract motifs inspired by local flowers and plants, outline quilted in ever-increasing ripples.

Detail of an appliquéd quilt, 1889; made by Caroline Roth, Marion county, Ohio

International Quilt Study Center at the University of Nebraska

Appliqué is used worldwide as a decorative technique for banners, clothing, and display pieces. Two examples are the molas made by the Kuna Indians of Panama, who employed the reverse-appliqué technique in which the upper layers of cloth are cut away to expose the lower layers. The intricate *paj ntaub* (Hmong: "flower cloth") made by Hmong women of Southeast Asia are delicate patterns

executed in appliqué and reverse appliqué with embroidered embellishments.

appoggiatura (from Italian *appoggiare*, "to lean"), in music, an ornamental note of long or short duration that temporarily displaces, and subsequently resolves into, a main note, usually by stepwise motion. During the Renaissance and early Baroque, the appoggiatura was of moderate length, averaging one-third of the main note, and was more in the nature of a melodic than a harmonic ornament. By the time of Johann Sebastian Bach (1685–1750), appoggiaturas were divided into two species: the short, which borrows an inconsiderable length from its main note and therefore has little effect on the harmony; and the long, which takes half or more of the length of its main note and therefore substantially affects the harmony, creating a dissonance that then resolves, on the main note, to a consonance. Because its purpose was mainly expressive, whether in purely melodic or harmonic terms, the typical appoggiatura in 17th- and 18th-century music occurred on the beat, rather than before it, "leaning" on the principal note, as suggested by the term's derivation.

The most common sign for the appoggiatura was a small note indicating the precise pitch of the ornament but only implying by relative size its duration, which depended largely upon the context and was governed by broadly acknowledged conventions. Convention also accounts for the fact that appoggiaturas were not always written out in Baroque music, even where their performance was taken for granted, as in the final cadences of operatic recitatives. In such instances, their omission by modern performers violates the composer's original intent.

The 19th-century tendency to notate the long appoggiatura in regular, rather than small, print foreshadowed the gradual abandonment of most embellishments, including the traditional symbol for the short appoggiatura, a small note with a slashed stem. The latter had in fact led to some confusion with the *acciaccatura*, a dissonant ornamental note played simultaneously with the main note but quickly released. Moreover, in 19th-century practice, grace notes, including the appoggiatura, were increasingly performed before the beat, and it was to take several generations of pioneering in the history of performance practice before the stylistic significance of the appoggiatura in pre-19th-century music was once again appreciated and understood.

Appomattox Court House, in the U.S. Civil War, site in Virginia of the surrender of the Confederate forces to those of the North on April 9, 1865. After an engagement with Federal cavalry, the Confederate Army of northern Virginia was surrounded at Appomattox, seat of Appomattox County, Va., 25 miles east of Lynchburg. Three miles to the northeast, at the former county seat, known as Appomattox Court House, Gen. Robert E. Lee surrendered to Gen. Ulysses S. Grant, thus effectively ending the Civil War. This location was virtually deserted after removal of the county seat to the new town of Appomattox in 1892 but was made a national historical monument in 1940; its buildings, including the McLean House, in which the surrender took place, were restored to their 1865 condition. In 1954 the 968-acre area was designated a historical park.

Apponyi, Albert, Gróf (Count) (b. May 29, 1846, Vienna—d. Feb. 7, 1933, Geneva), Hungarian statesman whose political philosophy blended the conservative traditions of his background with Hungarian nationalism.

Born into an ancient and famous family, he was the son of Count György Apponyi, who was leader of the Progressive Conservatives and chancellor from 1846 to 1848. Entering the Hungarian Parliament in 1872, Apponyi remained a member of it, with one short ex-

Apponyi, detail from a lithograph by an unknown artist

ception, until 1918. From the late 1880s, he was the leader of the "united opposition," which consisted of all parties hostile to the Austro-Hungarian "compromise" of 1867.

As minister of education (1906–10) in the coalition government, Apponyi introduced changes in the school curricula that were greatly resented by the non-Magyars for their Magyarizing tendencies. After the breakdown of the coalition he returned to the opposition as a member of the Party of Independence, of which he became president after Ferenc Kossuth's death (1914). He was again minister of education in 1917–18.

Apponyi returned to Parliament after World War I and headed the Hungarian peace delegation at Paris. He also represented Hungary several times at the League of Nations. When he died in 1933 he was serving as Hungarian delegate to the disarmament conference. His published works include several versions of his memoirs (Eng. trans., 1935) and many studies on Hungarian constitutional problems. Apponyi was one of the most brilliant orators in Hungarian public life.

apprenticeship, training in an art, trade, or craft under a legal agreement that defines the duration and conditions of the relationship between master and apprentice.

Early history. From the earliest times, in Egypt and Babylon, training in craft skills was organized to maintain an adequate number of craftsmen. The Code of Hammurabi of Babylon, which dates from the 18th century BCE, required artisans to teach their crafts to the next generation. In Rome and other ancient societies, many craftsmen were slaves, but, in the later years of the Roman Empire, craftsmen began to organize into independent collegia to uphold the standards of their trades.

By the 13th century a similar practice had emerged in western Europe in the form of craft guilds. Guild members supervised the product quality, methods of production, and work conditions for each occupational group in a town. The guilds were controlled by the master craftsmen, and the recruit entered the guild after completing his training as an apprentice—a period that commonly lasted seven years. It was a system suited to domestic industry, with the master working in his own premises alongside his assistants. This created something of an artificial family relationship in that the articles of apprenticeship took the place of kinship.

As time went on, however, governments had to contend with the exclusionary practices of the guilds, whose members could monopolize their trades in each town. Powerful guilds, for example, could levy high fees against outsiders to prevent them from entering a trade. Even apprenticeships could be restricted, with preference given to the sons of guild members or the sons of wealthy acquaintances. Responding to these improprieties, the English government tried to define the conditions of

apprenticeship with the Statute of Artificers of 1563, which attempted to limit exclusionary practices and to ensure adequate labour.

The notion of individual training extended beyond the craft guilds in the Middle Ages. For example, universities advanced the same principle with the master's degree, as did religious orders that required newcomers to pass through a novitiate. In medicine, the guild system applied to the surgeon, who also acted as barber and was regarded as a craftsman with less prestige than the physician. Lawyers served an apprenticeship by working in close association with a master of the profession.

Consequences of the Industrial Revolution. The Industrial Revolution altered attitudes toward training. Machines created a need for both skilled workers (such as machinists and engineers) and unskilled workers. Unskilled employees who showed aptitude advanced to semiskilled jobs. Apprenticeships actually grew in importance with the development of trade unions, which were created to uphold quality and control recruitment (by protecting union jobs).

In England apprenticeship was maintained by the craft industries and even extended to analogous fields. The education system, for example, offered various apprentice programs for student teachers, and there was a comparable system of training for young farmers.

Apprenticeship was fairly common in the American colonies, with indentured apprentices arriving from England in the 17th century. (Benjamin Franklin served as apprentice to his brother in the printing trade.) But apprenticeship in colonial America was less important than in Europe because of the high proportion of skilled workers in the colonies.

Because modernization and industrialization brought new impetus to the division of labour, the development of large-scale machine production increased the demand for workers with specialized skills. The more ambitious among them sought to increase their effectiveness and potential for advancement by voluntary study. To meet this need, mechanics' institutes were established, such as the one founded in London in 1823 by George Birkbeck, which still exists as Birkbeck College, and Cooper Union for the Advancement of Science and Art in New York City, established in 1859. In France technical education on a national scale dates from 1880.

Modern apprenticeship and vocational training. Early in the 20th century, assembly-line methods expanded the number of unskilled or semiskilled jobs, which made the long period of apprenticeship for skilled occupations unattractive. This led many countries to devise labour programs that made skilled jobs more accessible to the general population.

Apprenticeship remained a necessary part of craft industries, in spite of the mechanization that initially increased the number of jobs not requiring formal instruction. After World War I a new pattern of recruitment emerged. Apprenticeship on traditional lines was maintained for skilled craftsmanship; for less-skilled work, "learnership" became a common practice, providing the newcomer with opportunities to learn by working with others. Some industries introduced a system of upgrading, wherein labourers and unskilled workers were allowed to undertake skilled work after having served as assistants to other skilled workers. These training methods were supplemented by two approaches: pupil apprenticeship, whereby the recruit learned working skills with the intention of qualifying for an advanced position in the industry; and student apprenticeship, which allowed those with a university education, technical education, or working experience to qualify for employment.

Like the medieval guilds, the emerging trade unions restricted entry to skilled trades by means of rigorous apprenticeship, but they also created opportunities for semiskilled

workers to advance into skilled jobs. The formerly exclusive craft unions also began to change. From the 1920s they began to accept workers who had not entered as apprentices. As a result, the ratio of apprentices to journeymen ceased to be an issue.

The nature of apprenticeship changed greatly after World War II. Perhaps the most radical changes took place in West Germany, which had the advantage of a practically new start. There a distinction was made between skilled trades needing apprentices, semiskilled trades needing trainees, and handicrafts that employed artisans. Trades were grouped under local chambers of industry, handicrafts under chambers of handicrafts. The apprentice registered a contract with the appropriate chamber and kept a workbook that was inspected from time to time. There were also tests at monthly or quarterly intervals. Part-time attendance at a vocational school, included in the hours of employment, was compulsory until age 18.

In France vocational training came under the supervision of the Directorate of Technical and Vocational Education of the Ministry of Education. This created 24 national professional consultative commissions that represented employers, government, and trade unions. In 1930 the government began developing technical colleges to train a significant proportion of all skilled workers. Apprenticeship could be arranged by contract with a private employer, by attendance at school beyond the normal age of 16 (called the complementary course), or by apprenticeship to an artisan trade.

In Britain the Employment and Training Act of 1948 created a Central Youth Employment Executive and led to proposals for a National Joint Apprenticeship and Training Council to be set up in each industry. The printing trade, for example, introduced selection by objective testing of suitability and aptitude, while the motor-vehicle-repair industry developed an apprenticeship scheme for a national craftsman's certificate. The Post Office Engineering Department, which never accepted the traditional pattern of apprenticeship, developed a three-year course for recruits. But the most significant break with the past was the module system in the engineering industry, which provided a year's training in a wide selection of skills, followed by selected training in specialized skills. These were accompanied by performance tests and further education.

In the United States conditions of apprenticeship have typically been more flexible than those in Europe. This type of training is overseen by the Bureau of Apprenticeship and Training, established within the U.S. Department of Labor in 1937. While the lowest age for entry into the workforce is 16, many trades require a high-school diploma, which makes the effective entry age 18. The training period varies from two to five years, with much of the training taking place at technical and vocational schools. A trainee typically advances after passing qualifying examinations, with pay (from 60 to 90 percent of the journeyman's rate) increasing at each phase. In effect, American apprentices are indentured to the industry rather than to an employer.

In Japan apprenticeship and employee training have often featured a personal orientation rarely found in other industrial nations. Although this arrangement does not hold for most small and medium-sized companies, large Japanese companies have had a social obligation to provide lifelong work for employees who, in return, are required to continue with the same employer (until death or retirement)—no matter what the job assignment. Because Japanese apprenticeship emphasizes employment with a particular company, the close relationship between an apprentice and a specific trade, common elsewhere, is missing in Japan.

apprenticeship novel, biographical novel that concentrates on an individual's youth and his social and moral initiation into adulthood. The class derives from Goethe's *Wilhelm Meisters Lehrjahre* (1795-96; *Wilhelm Meister's Apprenticeship*). It became a traditional novel form in German literature, where it is called Bildungsroman ("novel of educational formation"). An English example is Dickens' *David Copperfield* (1850). In the 20th century Thomas Wolfe's *Look Homeward, Angel* (1929) is an American example. See also Bildungsroman; Künstlerroman.

approximant, in phonetics, a sound that is produced by bringing one articulator in the vocal tract close to another without, however, causing audible friction (see fricative). Approximants include semivowels, such as the y sound in "yes" or the w sound in "war."

apraxia, disturbance, caused by cerebral lesion, in the ability to carry out useful or skilled acts; motor power and mental capacity remain intact. Kinetic, or motor, apraxia results in one upper extremity's being affected so that the individual, even though there is no muscle weakness, cannot carry out fine motor acts, such as turning a key in a lock.

Ideational apraxia is the ultimate in absent-mindedness, the loss of capability to formulate a plan of action. The plan is never wholly organized, and even that part that is organized cannot be maintained sufficiently long to be carried out. Portions of the act may be completed but not in proper sequence. The individual may strike a match, for example, to light a campfire but then will hold the match until it burns his fingers. This type of apraxia is usually caused by diffuse lesions or toxemia in the cerebral cortex.

Ideokinetic apraxia is a condition brought about by an interruption of the association tracts, in which there is no coordination between ideation and motor activity. An affected individual will complain, for example, that he cannot use his hand, but then he will slap a mosquito with it. He is unable to perform certain acts (e.g., whistling or making a fist) upon command but is able to do so automatically. The cortical lesion responsible for ideokinetic apraxia is usually in the supramarginal gyrus and may be on one or both sides.

Constructional apraxia, which is caused more often by a lesion in the right cerebral hemisphere than in the left, is the inability to put together elements in the correct fashion to form a meaningful whole—e.g., being unable to build a structure with blocks or to copy a design.

Aprey faience, tin-glazed earthenware produced by the factory of Jacques Lallemand

Aprey faience plate decorated with exotic birds and flowers, second half of the 18th century; in the Victoria and Albert Museum, London

de Villehaut, Baron d'Aprey, established in 1744 on his estate at Aprey, near Dijon, Fr. The early pieces, which are heavy and rather crude, recall blue-and-white earthenware in the Rouen style or have Rococo forms decorated with chinoiserie (motifs influenced by the Chinese), flowers, and birds. From about 1772 to 1781 the activity of the painters Jacques Jarry and Antoine Mège established the factory's reputation for brilliant, exotically styled bird and flower decoration, with such devices as miniature landscapes on Rococo scrolls. Aprey continued to produce until the mid-19th century, but without distinction, copying earlier ware from its own molds.

apricot (*Prunus armeniaca*), stone fruit of the family Rosaceae, cultivated generally throughout the temperate regions of the world and used fresh for dessert, cooked in a variety of pastries, or preserved by canning or drying. Trees are large and spreading with broad,

Apricot (*Prunus armeniaca*)
Stephen Dalton

heart-shaped leaves, dark green in colour and held erect on the twigs. The flowers are white in full bloom and borne singly or doubly at a node on very short stems. The apricot sets fruit after self-pollination of its blossoms. The pit is smooth, somewhat like that of the plum but broader, somewhat flatter, and more winged. The fruit is nearly smooth, round to oblong in some varieties, somewhat flattened, and in general more like the peach in shape, but with little to no hairiness when ripe. Flesh is typically a rich yellow to yellowish orange. The kernels of some varieties are sweet, while others are poisonous.

Native to China, the apricot is cultivated in all of Central and Southeast Asia and in parts of southern Europe and North Africa. It was doubtless among the fruits brought into southern California early in the 18th century by Spanish missionaries. The American Pomological Society lists 11 varieties grown in the U.S. in 1879.

Apricots are propagated by budding on peach or apricot rootstocks, and the peach, plum, and apricot may be readily intergrafted. The tree succeeds in a well-drained loamy soil, preferably light rather than heavy. Most varieties withstand winter cold as well as peaches, but the blossom buds, opening earlier than those of the peach, are frequently killed by late freezes. The trees are quite drought-resistant and under favourable growing conditions are long-lived, some living 100 years or longer.

The leading country in apricot production is Spain. Other important producers are Iran, Syria, the U.S., France, and Italy.

Apricots are a good source of vitamin A and are high in natural-sugar content. Dried apricots are an excellent source of iron.

Apries, also spelled **OUAPHRIS**, Egyptian **HAABRA WAHIBRA**, Hebrew **HOPHRA** (d. 567 BC), fourth king (reigned 589–570 BC) of the 26th dynasty of Egypt; he succeeded his father, Psamtik II.

Apries failed to help his ally King Zedekiah of Judah against Babylon, but after the fall of Jerusalem he received many Jewish refugees into Egypt. Later he took the Phoenician port of Sidon, but, because of his subsequent failure in an attack on Cyrene in Libya, the Egyptian army mutinied and elected their general Ahmose as king instead (570). Apries was imprisoned but escaped; he later was murdered, perhaps by Egyptians.

April, fourth month of the Gregorian calendar. *See* month.

April Fools' Day, also called **ALL FOOLS' DAY**, first day of April, named from the custom of playing practical jokes or sending friends on fools' errands on that date. Although it has been observed for centuries in several countries, the origin of the custom is unknown. It resembles other festivals, such as the Hilaria of ancient Rome (March 25) and the Holi festival of India (ending March 31). Its timing seems related to the vernal equinox (March 21), when nature "fools" mankind with sudden changes in the weather.

On April Fools' Day all people are given an excuse to play the fool. In France the fooled person is called *poisson d'avril* ("April fish"), but the origin of the name is unknown. In April the cuckoo, emblem of simpletons, comes, so in Scotland the victim is called *gowk* (cuckoo). The custom of playing April Fools' jokes was taken to America by the British. It has continued to be observed by children and adults and sometimes involves rather elaborate hoaxes as well as merely simple jokes.

April Laws (Hungarian Revolution of 1848): *see* March Laws.

April Theses, Russian **APRELSKIYE TEZISY**, in Russian history, program developed by Lenin during the Russian Revolution of 1917, calling for Soviet control of state power; the theses, published in April 1917, contributed to the July Days uprising and also to the Bolshevik coup d'état in October 1917.

During the February Revolution two disparate bodies had replaced the imperial government—the Provisional Government and the Petrograd Soviet of Workers' and Soldiers' Deputies. The Socialists who dominated the Soviet interpreted the February Revolution as a bourgeois revolution and considered it appropriate for the bourgeoisie to hold power. They therefore submitted to the rule of the Provisional Government, formed by liberals from the Duma. The Soviet agreed to cooperate with the government and to advise it in the interests of workers and soldiers.

Lenin, however, viewed the two bodies as institutions representing social classes locked in the class struggle. He felt that, as one class gained dominance over the other, its governing body would crush the rival institution; thus the two could not indefinitely coexist. On the basis of this interpretation he developed his theses, in which he urged the Bolsheviks to withdraw their support from the Provisional Government and to call for immediate withdrawal from World War I and for the distribution of land among the peasantry. The Bolshevik Party was to organize workers, soldiers, and peasants and to strengthen the Soviets so that they could eventually seize power from the Provisional Government. The theses also called for the nationalization of banks and for Soviet control of the production and distribution of manufactured goods. Lenin first presented his theses to a gathering of Social Democrats and later (April 17 [April 4, old style], 1917) to a Bolshevik committee, both of which immediately rejected them. The

Bolshevik newspaper *Pravda* published them but carefully noted that they were Lenin's personal ideas.

Nevertheless, within a few weeks the party's seventh all-Russian conference (May 7–12 [April 24–29, old style]) adopted the theses as its program, along with the slogan "All Power to the Soviets." Although some Bolsheviks still had reservations about the program, the concepts contained in the theses became very popular among the workers and soldiers of Petrograd, who, using Bolshevik slogans, unsuccessfully tried to force the Soviet to take power in July. It was not until October, however, that Lenin's party was able to begin implementation of its program and seize power from the Provisional Government in the name of the Soviets.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

apse, in architecture, a semicircular or polygonal termination to the choir, chancel, or aisle of a secular or ecclesiastical building. First used in pre-Christian Roman architecture, the apse often functioned as an enlarged niche to hold the statue of a deity in a temple. It was also used in the *thermae* of ancient baths and in basilicas such as the imperial basilica in the Palace of Domitian on the Palatine Hill.

During the Early Christian era (c. 4th–mid-8th century), the domed apse became a standard part of the church plan, and from the time of Constantine I, it was placed at the west end of the basilica (e.g., Old St. Peter's). Between the 6th and 7th centuries the Roman branch of the Catholic Church changed the orientation of the apse to the east, as the Byzantine churches had done earlier. The apse

Apse, basilica of S. Vitale, Ravenna, 526–547
Alinari—Art Resource

was the most elaborately decorated part of the church, with the walls sheathed in marble and the vault ornamented with mosaic that depicted an embodiment of the godhead.

At the beginning of the 7th century, changing liturgical practices resulted in the addition of apses at the end of either the side aisles or the transept. In addition, the clergy moved

its seating from the apse to the choir, and the altar, which had previously been placed between the clergy and the main part of the church, was pushed into the apse. By the Renaissance the altar was often placed against the back wall. This arrangement removed the sacrifice of the mass from the congregation, an adjustment that eventually led, during the 17th century, to increased preaching in the nave of the church with mass said at the distant altar.

Variations to the apse also developed during the Romanesque period. Although the form of the apse remained simple in Italian architecture—gaining its exterior ornamentation from wall arcading, cornices, and buttressing—outside of Italy, particularly in France, an ambulatory (*q.v.*) and apse chapels were added to the main structure to form the complex chevet.

The apse has remained a standard part of ecclesiastic architecture through the 20th century, especially in churches that are designed from the traditional Latin cross or from centralized plans. *See also* church.

apse, also spelled *apsis*, plural *apsides*, in astronomy, either of the two points on an elliptical orbit that are nearest to, and farthest from, the focus, or centre of attraction. The line of apsides, connecting the two points, is the major axis of the orbit. The point nearest the focus is the pericentre, or periapsis, and that farthest from it is the apocentre, or apoapsis. Specific terms can be used for individual bodies: if the Sun is the centre, the specific terms perihelion and aphelion are generally used; if the Earth, perigee and apogee. Periastron and apastron refer to an orbit around a star, and perijove and apojove refer to an orbit around Jupiter.

Apsheron Peninsula (Azerbaijan): *see* Absheron Peninsula.

apteran: *see* dipluran.

apterygote, broadly, any of several types of small, primitive, wingless insects that belong to the subclass Apterygota (class Insecta) and are distinct from members of the subclass Pterygota, which contains the winged insects. Recent taxonomic revisions have raised three groups formerly classed among the apterygotes to the status of classes, parallel to the class Insecta. Thus the strict sense of apterygote no longer includes them but refers only to a subclass of Insecta that includes the silverfish, firebrats, and bristletails (order Thysanura) and the closely related Microcoryphia.

A brief treatment of apterygotes follows. For full treatment, *see* MACROPAEDIA: Insects.

The reclassified groups no longer considered strictly apterygotes are the Collembola, commonly known as springtails, the Diplura, or forktails, and the Protura. The true apterygotes, which are thought to be the evolutionary progenitors of winged insects, include the orders Thysanura, Microcoryphia, and the extinct Monura. These two groups are distinguished from one another by the positioning of their mouth apparatus: externally (ectognathous) in the Thysanura, Microcoryphia, and Monura and internally (entognathous) in the Collembola, Diplura, and Protura. Other taxonomically significant distinctions are based on the position of eyes, the number of body segments, and the structure of legs and antennae. All of these organisms may be referred to simply as hexapods.

The extant hexapods range in size from the Protura, which attain a maximum length of 2 mm (0.08 inch), to some Diplura that may reach 50 mm; most are under 10 mm. Most are yellow or white in colour, and all but Protura and Collembola have single or double tail filaments. Collembola are the most various and widely distributed, with over 3,500 known species. Antennae and optical structures also differ among these varieties. All of

the hexapods inhabit soil, leaf litter, and other forms of organic debris. Since the epidermal layers of the hexapods are thin and allow free passage of air and water vapour, the presence of moisture is essential to their survival. Hexapods generally feed on fungi, decayed vegetation, algae, and spores, but silverfish also consume carrion and even paper products. Apterygotes are preyed upon by certain species of flies, beetles, and ants, and occasionally by fish and reptiles.

The bodies of all hexapods are composed of three sections (except those of the extinct Monuran group, which contained 14 segments): the abdomen, thorax, and head. The thorax is in turn divided into three segments, each bearing one pair of legs that terminate in claws. Most breathe through their outer layer (cutaneous respiration), though some varieties have developed breathing systems with tracheae and thoracic orifices (spiracles). On the abdomen of the Collembola, appendages that were once limbs have developed into a spring-like leaping mechanism called a furcula and a tenaculum that controls the furcula. The Diplura, Microcoryphia, and Thysanura have sensory appendages (cerci) on the abdomen that are also modified limbs. The sensory apparatus of the hexapod head varies widely: Diplura have none at all, while Collembola frequently have simple eyes called ocelli in addition to their other sensory organs, and Microcoryphia have both ocelli and compound eyes.

Sexual reproduction is characteristic of the hexapods, although eggs can sometimes develop without fertilization (a process known as parthenogenesis). Typically, sperm is dropped in packets at random by males and retrieved by females, which retain the packets until they are needed for fertilization or until they are lost during a succeeding molt. Apterygote young, sometimes called nymphs, molt periodically with little physical change. Molt sometimes continues throughout their life cycle. Collembola may go through up to 50 instars (stages between molts) with little actual growth taking place between them. Microcoryphia generally molt six times during a life span, while the total for Thysanura is often over 40.

Populations of Collembola, the most common apterygote, are highly sensitive to the condition of microscopic vegetative growth in the soil. Often existing in densities of 100,000 or more per cubic metre of soil, Collembola are susceptible to some insecticides and are normally unaffected by herbicides. Different species of Collembola and members of the same species at different stages of growth tend to inhabit different strata of the soil. Like most soil-dwelling insects, apterygotes may serve a valuable function in soil aeration and enriching processes.

Aptian Stage, the fifth of six main divisions (in ascending order) in the Lower Cretaceous Series, representing all those rocks deposited worldwide during the Aptian Age (119 to 113 million years ago). No global stratotype section and point (GSSP) for the base of the Aptian Stage has been approved by the International Commission on Stratigraphy. The name of the stage is derived from the town of Apt in Vaucluse *département* in southeastern France, for which the surrounding area serves as the classic type district for rocks of this age.

In England the Aptian Stage is represented by part of the Lower Greensand formation. Elsewhere in northern Europe it consists of portions of the thick Hils Clay, while in the United States it includes the Dakota Sandstone. The first occurrence of the ammonite cephalopod *Prodeshayesites* marks the base of the Aptian Stage in England, Germany, and France. The calcareous nannofossil biozones of *Nannoconus bucheri* and *N. wassalli* and the fossil zones of the planktonic foraminifera

Globigerinelloides algerianus and *G. blowi* are also considered diagnostic for rocks of this stage. Rocks of the Aptian Stage overlie those of the Barremian Stage and are overlain by rocks of the Albian Stage.

aptitude test, examination that attempts to determine and measure those characteristics of a person that are regarded as indices of his capability to acquire, through future training, some specific set of responses (intellectual, motor, and so on). The tests assume that people differ in their special abilities and that these differences are related in a predictable manner to their later achievements. General, or multiple, aptitude tests are similar to intelligence tests in that they measure a broad spectrum of abilities (*e.g.*, verbal comprehension, general reasoning, numerical operations, perceptual speed, mechanical knowledge). They yield a profile of scores rather than a single IQ and are widely used in educational and vocational counseling. Aptitude tests have also been developed to measure professional potential and capabilities (*e.g.*, legal, medical) and special abilities (*e.g.*, clerical, mechanical).

Apu-Punchau (Inca religion): *see* Inti.

Apuleius, Lucius (b. c. 124, Madauros, Numidia [near modern Mdaourouch, Alg.]—d. probably after 170), Platonic philosopher, rhetorician, and author remembered for *The Golden Ass*, a prose narrative that proved influential long after his death. The work, called *Metamorphoses* by its author, narrates the adventures of a young man changed by magic into an ass.

Apuleius, who was educated at Carthage and Athens, traveled in the Mediterranean region and became interested in contemporary religious initiation rites, among them the ceremonies associated with worship of the Egyptian goddess Isis. Intellectually versatile and acquainted with works of both Latin and Greek writers, he taught rhetoric in Rome before returning to Africa to marry a rich widow, Aemilia Pudentilla. To meet her family's charge that he had practiced magic to win her affection, he wrote the *Apologia* ("Defense"), the major source for his biography.

For *The Golden Ass* it is likely that he used material from the lost *Metamorphoses* by Lucius of Patrae, which is cited by some as the source for the brief extant Greek work on a similar theme, *Lucius, or the Ass*, attributed to the Greek rhetorician Lucian. Though Apuleius' novel is fiction, it contains a few definitely autobiographical details, and its hero has been seen as a partial portrait of its author. It is particularly valuable for its description of the ancient religious mysteries, and Lucius' restoration from animal to human shape, with the aid of Isis, and his acceptance into her priesthood suggests that Apuleius himself had been initiated into that cult. Considered a revelation of ancient manners, the work has been praised for its entertaining and at times bawdy episodes that alternate between the dignified, the ludicrous, the voluptuous, and the horrible. Its "Cupid and Psyche" tale (Books 4 through 6) has been frequently imitated by later writers, including the English poets Shakerley Marmion in 1637, Mary Tighe in 1805, William Morris in *The Earthly Paradise* (1868–70), and Robert Bridges in 1885 and 1894, and C.S. Lewis in the novel *Till We Have Faces: A Myth Retold* (1956). Some of Lucius' adventures reappear in *The Decameron* by Giovanni Boccaccio, in *Don Quixote* by Miguel de Cervantes, and in *Gil Blas* by Alain Le Sage. Of Apuleius' other literary works his *Florida* is, like *The Golden Ass*, stylistically affected.

More influential than this collection of the author's declamations on various subjects are

his philosophical treatises. He wrote three books on Plato (the third is lost): *De Platone et eius dogmate* ("On Plato and His Teaching") and *De Deo Socratis* ("On the God of Socrates"), which expounds the Platonic notion of demons, beneficent creatures intermediate between gods and mortals. His *De mundo* ("On the World") adapts a treatise incorrectly attributed to Aristotle. Apuleius asserts that he wrote a number of poems and works on natural history, but these works are lost. The noted *Asclepius*, a Latin translation of a (now lost) Greek Hermetic dialogue, has been wrongly attributed to him. His collected works were first edited by Joannes Andreas (1469); later editions in Latin include a three-volume collection by Rudolf Helm and Paul Thomas (1905–10) and the *Index Apuleianus* by William Abbott Oldfather, Howard Vernon Canter, and Ben Edwin Perry (1934). In English, *The Works of Apuleius* was edited by Hudson Gurney in 1853, and modern editions appear in the *Loeb Classical Library* series.

Apulia (Italy): see Puglia.

Apure, *estado* ("state") in the Llanos (plains) of southwestern Venezuela. It is bounded on the north by Táchira, Barinas, and Guárico states and the Apure River, on the east by Bolívar state and the Orinoco River, and on the south and west by Colombia.

The state is famous for its *llaneros* (cowboys), who were key fighters in the independence movement of the early 19th century. Mounted *llaneros* still work the area's large cattle ranches, which have driven the local economy from the time of the first European settlements. Drainage is poor, and annual floods are extensive and prolonged. During the harsh dry season the savanna grasses become virtually inedible, and many cattle are driven to wetter areas as far east as the Orinoco River. San Fernando de Apure (*q.v.*), the state capital and main population centre, has a large meat-packing industry, from which fresh beef is flown to Caracas and other large cities. Area 29,500 square miles (76,500 square km). Pop. (1995 est.) 376,220.

Apure River, Spanish RÍO APURE, river in western Venezuela. The major navigable tributary of the Orinoco River, it arises in the Cordillera de Mérida and flows for 510 miles (820 km) northeast and east through the heart of the Llanos (plains), Venezuela's most important cattle-raising area. The river's principal tributaries, including the Portuguesa and the Guárico, flow mainly from the north. During the rainy season (May to November), the Apure is navigable for small boats from Ciudad Bolívar up to San Fernando de Apure and Puerto de Nutrias. Since 1957 the highway connecting San Fernando de Apure with Calabozo and the densely populated north has reduced river traffic drastically.

Apurímac, *departamento*, *Inca región*, in the Andean interior of southern Peru. Most of the land is at a high elevation, dissected with deep canyons cut by the Apurímac River and its tributaries. The inhabitants are mainly subsistence farmers and herders. The chief products are sheep and alpaca wool, corn (maize), and potatoes. Wheat, beans, and fruits also are grown. Gold, copper, and lead are mined. The capital, Abancay (*q.v.*), is in the centre of the largest area of settlement, located in an intermontane basin that lies between 7,000 and 8,000 feet (2,100 and 2,400 m) above sea level. Area 6,050 square miles (15,670 square km). Pop. (1993 est.) 381,997.

Apurímac River, Spanish RÍO APURÍMAC, river in southern Peru. Owing to its lengthy Andean tributaries, it is the farthestmost source of the Amazon River. Arising at roughly

17,000 feet (5,200 m) from the snowmelts of Mount Mismi in Arequipa *departamento*, Peru, it flows northwest through the Andes, descending to less than 860 feet (260 m) to join the Urubamba and form the Ucayali River. For most of its 430-mile (700-kilometre) length, it flows through narrow canyons, and its torrential course is frequently interrupted by falls and rapids. It is known as the Apurímac only to the junction of the Mantaro River. From there to the Perené it is known as the Ene, and from the Perené to the Urubamba it is known as the Tambo.

Apuseni Mountains, Romanian MUNȚII APUSENI, large mountain chain, a subgroup of the Carpathians, lying north of the Mureș River, northwestern Romania. The Apuseni (Western) Mountains are not high—reaching a maximum elevation of only 6,066 feet (1,849 m)—but as a uniform, imposing group they dominate the low surrounding area. Central to the group, and the highest, is the Bihor Massif (*q.v.*), from which radiate six lower mountain groups. To the west the Crișul (Hungarian: Körös) River system drains the massif onto the Great Alföld; to the east stretches the Transylvanian Basin. The streams off the southern groups flow into the Mureș River. The mountains' rounded crests contrast with deep river valleys, and extensive limestone formations give rise to some spectacularly eroded scenery. Pastureland and settlements are scattered among the mountains, and the Metaliferi (Metal) Mountains in the south, with volcanic conical crests, are rich in mineral ores.

Aq Qoyunlu (Turkmen tribal federation): see Ak Koyunlu.

Āqā Khān: see Aga Khan.

Āqā Mirak, also spelled ĀGHĀ MĪRAK, in full SAYYID ĀQĀ JALĀL AD-DĪN MĪRAK AL-ĤASANĪ (fl. 16th century), Persian painter, an admired portraitist and an excellent colourist, who painted in a sumptuous style.

"Faridun Tests His Sons in the Guise of a Dragon," miniature by Āqā Mirak, c. 1527–28, from the *Shāh-nāmah* ("Book of Kings") by Ferdowsi; in the Metropolitan Museum of Art, New York City

By courtesy of the Metropolitan Museum of Art, New York, Collection of Arthur A. Houghton

A descendant of the Prophet Muḥammad and a native of Eṣfahān, he worked mostly in Tabriz, the capital of the Ṣafavid empire. He knew the Persian painter Behzād, who was director of the royal library and its manager of manuscript illustration. Āqā Mirak, as one of the senior court artists, was a colleague of the highly regarded painter Sulṭān Muḥammad. He also was the teacher of Shāh Qūlī, a Persian painter later active at the court of the Ottoman sultan Süleyman the Magnificent.

A bon vivant and poet, Āqā Mirak became a boon companion of the Ṣafavid Shāh Tah-māsp I, who was a committed patron of the arts.

Āqā Rezā: see Rezā.

Aqaba, Gulf of, Arabic KHALIJ AL-'AQABAḤ, northeastern arm of the Red Sea, penetrating between Saudi Arabia and the Sinai Peninsula. It varies in width from 12 to 17 miles (19 to 27 km) and is 100 miles (160 km) long. The gulf lies in a pronounced cleft between hills rising abruptly to about 2,000 feet (600 m). Navigation is difficult because of the gulf's narrow entrance at the Straits of Tiran and its islands, coral reefs, and sudden squalls. The

Beach on the Gulf of Aqaba

Photo Research International

Gulf of Aqaba is part of the complex East African Rift System, and its head touches the Egyptian, Israeli, Jordanian, and Saudi Arabian boundaries. Although Dhahab (Dahab), Egypt, is the only sheltered harbour along the gulf, Jordan and Israel created the ports of Al-'Aqabah and Elat, respectively, as outlets to the Red Sea and the Indian Ocean.

'Aqabah, Al-, also spelled AQABA, or AKABA, Latin AELANA, port town, extreme southwestern Jordan. It lies on the Gulf of Aqaba, an inlet of the Red Sea, just east of the Jordan-Israel frontier on the gulf. It is Jordan's only seaport. Because of freshwater springs in the vicinity, it has been settled for millennia; King Solomon's port and foundry of Ezion-geber lay nearby.

In Roman times Al-'Aqabah was, under Trajan's rule (AD 98–117), garrisoned by a Roman legion and was the southern terminus of a trade route leading from Syria. Under Byzantine rule it became the seat of a bishopric in the early 4th century. Conquered by Muḥammad in 630/631, it became an important way-station for Egyptian Muslims making the pilgrimage to Mecca. The town was taken by the crusaders (12th century) and finally returned to Muslim rule in 1183. Al-'Aqabah declined under Ottoman rule; at the beginning of the 20th century it was only a small village. Its pilgrim traffic had largely disappeared following the opening of the Suez Canal (1869) and the completion of the Hejaz Railway (1908).

A strategic fortified Turkish outpost in World War I, Al-'Aqabah was bombarded by the British and French navies and captured by Arab irregulars led by T.E. Lawrence in July 1917. After the war the status of Al-'Aqabah was in dispute. When King Ibn Sa'ūd conquered the Hejaz (1925), the British placed Al-'Aqabah and the Ma'ān district under Transjordanian authority; this de facto situation continued when Jordan became fully independent (1946). Saudi Arabia had never agreed to these frontiers, which were a matter of dispute until 1965.

Al-'Aqabah's harbour, somewhat improved by the British in World War II, was greatly modernized under independent Jordan; deep-water facilities were opened in 1961. The port's principal export is Jordanian bulk phosphates; imports are chiefly manufactured goods. Pop. (1993 est.) 64,300.

Aqhat Epic, ancient West Semitic legend probably concerned with the cause of the an-

nual summer drought (in the eastern Mediterranean). The epic records that Danel, a sage and king of the Haranamites, had no son until the god El, in response to Danel's many prayers and offerings, finally granted him a child, whom Danel named Aqhat. Some time later Danel offered hospitality to the divine craftsman Kothar, who in return gave Aqhat one of his marvelous bows. That bow, however, had been intended for the goddess Anath, who became outraged that it had been given to a mortal. Anath made Aqhat a variety of tempting offers, including herself, in exchange for the bow, but Aqhat rejected all of them. Anath then plotted to kill Aqhat, luring him to a hunting party where she, disguised as a falcon, carried her henchman, Yatpan, in a sack and dropped him on Aqhat. Yatpan killed Aqhat and snatched the bow, which he later carelessly dropped into the sea.

Meanwhile, because of the blood shed in violence, a strange famine came over the land, leading Aqhat's sister and father to discover the crime and to set about avenging it. The conclusion is not known, however, because the legend's main text breaks off at that point.

The legend appears to have been a seasonal myth designed to account for the earth's barrenness during the dry summer months. Presumably the rest of the text related how fertility returned to the earth, either through the resurrection of Aqhat or through the fathering of a new family by Danel.

ʿāqil (Arabic: "knowledgeable"), in Islāmic law, one who is in full possession of his or her mental faculties. Such a person is legally responsible for his or her actions and punishable for any deviation from religious commandments. *ʿĀqil* is often used with the adjective *bāligh* ("grown-up," or "of age") in contrast to *qāṣir* ("juvenile"). In Islāmic law, a *qāṣir* cannot qualify as a witness in court without consideration of his or her mental capabilities. For this reason many Muslim scholars directly relate *ʿāqil* to a person's age. Though there is no uniform opinion on the exact age at which an individual becomes an *ʿāqil*, the years 13 to 15 are often mentioned.

Aqmola, formerly (until 1961) AKMOLINSK or (1961–92) TSELINOGRAD, and from 1998 ASTANA, city, capital of Kazakstan. Aqmola lies in north-central Kazakstan along the Ishim River at the junction of the Trans-Kazakstan and South Siberian railways.

It was founded in 1824 as a Russian military outpost and became an administrative centre in 1868. Its population had reached 33,000 when it was made an *oblast* (province) centre in 1939. The city's importance was greatly enhanced during the Soviet period by the government's Virgin and Idle Lands Campaign of the mid-1950s—Tselinograd was Russian for "City of the Virgin Lands"—and by the city's role as capital of a *kray* (region) that united the five northern provinces of the Kazakh S.S.R. in 1960–65. There was much new construction, and various research and higher educational institutions were established.

The city's name was changed to Aqmola (Kazak: "White Grave") in 1992 following Kazakstan's independence. In 1994 the Kazak government resolved to transfer the national capital from Almaty to Aqmola, a process completed in 1997, and the city's name was again changed the following year to Astana ("Capital"). Much of the population is employed by the railways. Various types of agricultural machinery are also produced. Pop. (1999) 313,000.

ʿAqqād, ʿAbbās Maḥmūd al- (b. June 28, 1889, Aswān, Egypt—d. March 12, 1964, Cairo), Egyptian journalist, poet, and literary critic who was an innovator of 20th-century Arabic poetry and criticism.

Born in modest circumstances, al-ʿAqqād continued his education through reading when

his formal schooling was cut short. He supported himself throughout most of his career by writing. An outspoken political commentator, he was imprisoned for some months in 1930–31 for remarks opposing the government. In 1942, with the advance of German troops, al-ʿAqqād sought refuge in the Sudan as a precaution against German reprisals for his criticisms of Adolf Hitler.

Al-ʿAqqād's literary works included poems; a novel, *Sarāh* (1938), based on one of his own romances; and critiques of classical and modern Arabic authors. His essays show the influence of 19th-century English essayists, particularly Thomas Carlyle.

Al-ʿAqqād devoted much thought to religion and politics, and his works include studies of the philosophy of the Qurʾān, of political and social philosophy, and biographies of various Muslim leaders.

Aqtöbe, formerly AKTYUBINSK, city, northwestern Kazakstan, on the Ile River. It was founded in 1869 as Aktyube ("White Hill"), a small Russian fort; the first Russian peasant settlers arrived in 1878. In 1891 it became the capital of an *uyezd* (canton) and in 1932 of an *oblast* (province). During World War II a ferroalloys plant was built to smelt the nickel and chromium ores of the Mughalzar (Mugodzhar) Hills. Now an important industrial centre, Aqtöbe produces chromium compounds, X-ray apparatus, and parts for agricultural machinery and has stockyards and flour mills. Cultural assets include a teacher-training and a medical institute, a theatre, several museums, and a planetarium. Pop. (1999) 253,100.

aqua ammonia: see ammonium hydroxide.

aqua regia, mixture of concentrated nitric and hydrochloric acids, usually one part of the former to three parts of the latter by volume. This mixture was given its name (literally, "royal water") by the alchemists because of its ability to dissolve gold and other so-called noble metals.

Aqua regia and other mixtures similar to it are used in analytical procedures for the solution of certain iron ores, phosphate rocks, slags, nickel-chromium alloys, antimony, selenium, and some of the less soluble sulfides, such as those of mercury, arsenic, cobalt, and lead.

aquaculture, also called FISH FARMING, FISH CULTURE, or MARICULTURE, an approximate equivalent in fishing to agriculture—that is, the rearing of fish, shellfish, and some aquatic plants to supplement the natural supply. Fish are reared under controlled conditions all over the world.

Fish may be confined in earth ponds, concrete pools, barricaded coastal waters, or cages suspended in open water. In these enclosures, the fish can be supplied with adequate food and protected from many natural predators.

While most fish farming is devoted to the commercial food market, many governmental agencies engage in it to stock lakes and rivers for sport fishing; there is, in addition, a steady commercial market for goldfish and other decorative fish for home aquariums. Aquaculturists also raise bait fish for both sport and commercial fishing.

Ocean ranching by governments is intended to restock lakes and oceans. The young fish are bred in the controlled environment and when sufficiently mature are released into the open sea. Oysters (as a source of both food and pearls), scallops, and mussels are raised throughout most of the world. Carp, trout, catfish, and tilapia are also widely raised. Experiments with ocean ranching in the late 20th century led to the economically successful aquaculture of lobsters.

aquaculture (plants): see hydroponics.

aquamarine, pale greenish blue or bluish green variety of beryl (*q.v.*) that is valued as a gemstone. The most common variety of gem beryl, it occurs in pegmatite, in which it forms much larger and clearer crystals than emerald (one completely transparent crystal from Brazil weighed 110 kg [243 pounds]). It can also be found in mica schists. Aquamarine occurs in Brazil, which is the chief source; the Urals, Russia; Madagascar; Sri Lanka; India; and Maine, New Hampshire, Connecticut, North Carolina, and Colorado in the United States. Heat treatment is sometimes employed to improve the colour of gem beryls.

aquarelle, technique of painting in transparent, rather than opaque, watercolours. Although aquarelle was known to the ancient Egyptians, it did not achieve popularity in Europe until the 18th and 19th centuries. It was used especially in France and England by landscape painters.

aquarium, receptacle for maintaining aquatic organisms, either freshwater or marine, or a facility in which a collection of aquatic organisms is displayed or studied.

Historical background. The earliest known aquarists were the Sumerians, who kept fishes in artificial ponds at least 4,500 years ago; records of fish keeping also date from ancient Egypt and Assyria. The Chinese, who raised carp for food as early as 1000 BC, were probably the first to breed fish with any degree of success. Their selective breeding of ornamental goldfish was later introduced to Japan, where the breeding of ornamental carp was perfected. The ancient Romans, who kept fish for food and entertainment, were the first known marine aquarists; they constructed ponds that were supplied with saltwater from the ocean. Although goldfish were successfully kept in glass vessels in England during the middle 1700s, aquarium keeping did not become well established until the relationship between oxygen, animals, and plants became known a century later.

By 1850 the keeping of fishes, amphibians, and reptiles had become useful in the study of nature. It was in the works of Philip Gosse, a British naturalist, that the term aquarium first appeared. His work aroused increased public interest in aquatic life. The first display aquarium was opened to the public in 1853 at Regent's Park in London. It was followed by aquariums in Berlin, Naples, and Paris. P.T. Barnum, the circus entrepreneur, recognized the commercial possibilities of living aquatic animals and, in 1856, opened the first display aquarium at the American Museum in New York City as a private enterprise. By 1928 there were 45 public or commercial aquariums throughout the world, but growth then slowed and few new large aquariums appeared until after World War II.

Many of the world's principal cities now have public aquariums as well as commercial ones. Another category encompasses those aquariums that serve chiefly as research institutions. Among the best known of the latter are those at Naples; the Oceanographic Museum of Monaco; Plymouth Marine Laboratory, Eng.; and Scripps Institution of Oceanography, La Jolla, Calif.

In 1938 the first oceanarium, or large marine aquarium, Marineland, opened near St. Augustine, Fla., as a private enterprise; it featured a giant community fish tank and trained dolphins. The Seaquarium, Miami, is similar. The emphasis in this type of aquarium is on very large tanks, up to 1,000,000 gallons each, in which a great variety of fishes is placed with no attempt to separate them. In the formal aquarium (*e.g.*, the Shedd Aquarium, Chicago), the kinds and types of fishes are separated.

Design and architecture. The first containers specifically designed for aquatic specimens were the strictly functional open-air tanks used by the Romans to preserve and fatten fish for market. It was not until the 18th century that the importation of goldfish into France from the Orient for aesthetic enjoyment created the demand for small aquariums; ceramic bowls, occasionally fitted with transparent sections, were produced. In the large public aquariums built in many European cities between 1850 and 1880, efforts were made to create the illusion that the spectator was entering into the underwater world. More recently, the trend has been to emphasize the natural beauty of the specimens and to make a sharp distinction between the water and the viewing space.

Regardless of size—whether a small jar with a capacity of less than one gallon or a huge tank with a capacity of more than 1,000,000 gallons—aquariums must be constructed with care; many substances, especially plastics and adhesives, nontoxic to humans, are toxic to water-breathing animals.

Glass is probably the safest basic material, although polyethylene, polypropylene, acrylic plastics (Plexiglas), and fluorocarbon plastics are normally nontoxic. Fibre glass has been widely used and is nontoxic if properly prepared. Adhesives for sealing include epoxy resins, polyvinyl chloride, silicone rubber (except for certain coloured preparations), and neoprene. Metals are not usually used, especially in seawater, which is highly corrosive. Stainless steel, however, has a low toxicity, and is often used, especially in freshwater systems.

A small aquarium can be constructed entirely of glass and without supporting frames by using silicone rubber as an adhesive. Fibre glass is probably the most practical supporting material for all but the largest tanks since it is lightweight, strong, does not deteriorate, and is easily fabricated into any shape. Wood, though widely used, is subject to rot and boring organisms and thus must be protected. Reinforced concrete, including special mixes for seawater, is the principal supporting material used in the construction of large aquariums.

In modern aquariums tanks of a variety of sizes and shapes are often grouped together in order to avoid the "boxes of fish" look that characterizes some of the older, formal aquariums. Dry dioramas at the rear of the tank create the illusion of distance; the tank habitat can be a natural one or one in which fibre glass has been impregnated or painted to duplicate almost any environment. Modern aquariums attempt to illustrate the natural environment of the specimens displayed.

Polished plate glass, fully tempered polished plate glass, and Plexiglas are the most commonly used glazing materials. Polished plate glass is usually used only in small aquariums because it breaks into large pieces when it fails. One generally accepted practice is to glaze large tanks with two or three layers of tempered glass so that if breakage occurs it is confined to one layer. Although Plexiglas is easily scratched, it can be repolished.

Accessories for individual tanks normally include filters, air pumps, lights, and electric thermostatically controlled immersion heaters, or perhaps alternately, some means of chilling the water. In aquarium buildings the tanks are usually grouped so that they have a common filter and method of temperature control. Water sterilizers may be included. Plumbing in large aquariums with multiple systems is sometimes complex, involving a variety of automatic controls and water-quality monitoring systems. Because of its cost and fragility, glass plumbing (e.g., for aeration or circulation of water within an aquarium) is used only in cases in which low toxicity is essential. Unplasticized polyvinyl chloride pipe is

widely used. Fibre-glass pipe and epoxy-lined asbestos pipe are sometimes used, but lead and hard rubber pipe are obsolete. In seawater systems the growth of fouling organisms such as mussels and barnacles is avoided by providing the system with duplicate pipes and alternating their use on a weekly basis. When a line is dry, the few organisms present die and are flushed out when the line is again put into service.

Nonmetallic or plastic-lined pumps are better than metal ones in terms of toxicity, but stainless steel is often satisfactory. Airlift pumps (such as those used in home aquarium subsand filters) move large volumes of water when the lift pipes are of sufficient diameter.

Generally, the most effective illumination is by incandescent lamps placed above the front glass. Fluorescent lights provide even illumination but may overilluminate the tank walls; coloured lights accentuate natural colours; and mercury-vapour lamps encourage maximum growth of marine plants.

The introduction of some form of aquatic plant life is of practical value in an aquarium, although the presence of plants can cause complications. Aquatic plants consume dissolved oxygen and give off carbon dioxide; under the influence of bright light, plants also consume carbon dioxide and give off oxygen while engaged in photosynthesis. In turn, the waste products of the fishes form fertilizer or food for the plants and are consumed by them. This operates very well so long as light of a certain intensity falls on the plants—the animals thus give off what the plants can use and vice versa. Aquariums in which the plants and animals are believed to balance each other in the respiratory process are generally referred to as balanced aquariums.

Maintenance problems. The design of a large aquarium must take into account the requirements of the specimens, especially since exhibits at modern aquariums include all types of aquatic organisms: mammals, birds, reptiles, amphibians, and invertebrates as well as fishes. Among the many factors that must be considered are traffic flow patterns of visitors, reflections off glass, acoustics, and tank-maintenance problems such as water clarity, dissolved wastes, temperature, tank decor, disease treatment, and nutrition.

The primary requirement for maintaining aquatic organisms is water quality. The water supply must be free of pollutants, including sewage and industrial wastes, and it should be in gaseous equilibrium with the atmosphere to ensure adequate oxygen and to avoid supersaturation with nitrogen. In recirculating systems, water treatment must not only ensure clarity of the water but also purification of metabolic wastes. The source of fresh water is usually water supplies from which chlorine and other additives have been removed, either by carbon filtration or by the addition of a chemical. Marine organisms can be maintained in either natural or artificial seawater; the latter has the advantage of being initially free from disease-causing organisms and pollutants but may not be as suitable for some organisms.

There are three basic types of water systems: open, closed, and semiclosed. In open systems the water flows through the aquarium once and is discarded. This provides water quality comparable to that of the natural environment and there is no buildup of toxic metabolic wastes; however, temperature control and pumping are usually costly, and filtration often is necessary.

Water is continuously recirculated in closed systems and is only renewed periodically. Metabolic wastes must be treated since they are not continuously flushed from the system. An important problem is that ammonia must be rapidly removed or transformed because it is harmful even at very low concentrations. In the aquarium the bacteria that convert am-

monia to nitrite reside primarily in the filter material, and a slow sand filter with a large surface area is usually provided to ensure their abundance. Plant growth in the aquarium, especially in marine systems, is not usually sufficient to utilize all the nitrate produced by bacteria from nitrite. Although some aquariums have operated many years with a minimum of water renewal, it is normally necessary to replace from 1 to 10 percent of the water per month to maintain a low level of nitrates. The use of charcoal in both fresh water and seawater systems helps to slow the accumulation of nitrogenous wastes. Metabolic wastes also cause an increase in the acidity of the water. Carbonate compounds are commonly used to maintain an optimal level of acidity, particularly when water renewal is infrequent.

Semiclosed systems are essentially the same as closed except that there is a constant connection to the water supply, and the problem of dissolved wastes is controlled by the regular addition of new water; this system is less costly than the open one with regard to temperature control and pumping.

Filters vary from simple flow-through systems to completely automated recirculating systems, with special provisions for monitoring and controlling the physical and chemical characteristics of the water.

The turnover rate, or rate of water replacement, of individual aquariums is important and should be no more than two hours. In addition, aeration by means of air stones (diffusers) should be provided to guard against asphyxia in the event of an unexpected water-supply failure.

Fishes and invertebrates can also be maintained without filtration or aeration in aquariums that are "balanced" with plants; however, the balance between plants and animals is very difficult to attain on a large scale or even in a normally stocked aquarium, especially a seawater aquarium.

Freshwater pools for mammals and birds present special problems. They generally require a higher filtration rate and greater filter capacity because they accumulate large amounts of fecal wastes. Air-breathing animals, however, are not highly sensitive to water quality; thus, chemical treatments, such as chlorination, which would kill fishes, can be used to control bacteria and to improve water clarity. Seawater formulas are simpler; for example, a 2 percent sodium chloride solution will satisfactorily maintain whales and dolphins. Seals and sea lions have been kept in fresh water, but this may increase their eye problems because of the osmotic effect of the fresh water on the eye tissues.

Aquarius (Latin: Water Bearer), in astronomy, zodiacal constellation lying between

Aquarius, illumination from a Book of Hours, Italian, c. 1475; in the Pierpont Morgan Library, New York City (MS. G.14)

By courtesy of the Pierpont Morgan Library, New York, the Glazier Collection

Capricornus and Pisces, at about 23 hours right ascension (the coordinate on the celestial sphere analogous to longitude on the Earth) and 10° south declination (angular distance south of the celestial equator). It lacks striking features, the brightest stars being only of the third magnitude.

In astrology, Aquarius is the 11th sign of the zodiac, considered as governing the period c. January 20–c. February 18. Its representation as a man pouring a stream of water out of a jug came about, it has been suggested, because in ancient times the rising of Aquarius coincided in the Middle East with a period of floods and rain. In the conceptual scheme of the "Great Year"—the more than 25,000 years it takes the Earth to pass in turn through the influence of each of the signs of the zodiac—the Earth is said to have passed into the age of Aquarius early in the 19th century.

aquatic locomotion, in animals, movement through water either by swimming or by progression in contact with the substrate (*i.e.*, the bottom or other surfaces).

Free-swimming locomotion is found in animals ranging from protozoans to whales. For effective swimming the animal controls its buoyancy and has a propulsion system able to compete with the resistance of water movements. Many invertebrates, especially mollusks, propel themselves by water jets; others use undulatory movements of their soft parts. The most widespread mechanism, however, is some means (*e.g.*, a paddle) of physically pressing against the water. This may take the form of anguilliform (undulatory) movements in eel-like fishes; using the forelimbs as in turtles and penguins, hind limbs as in frogs and many diving birds, or all four limbs as in bears and most other terrestrial mammals. Highly evolved swimmers, such as whales and bony fishes, have the thrust concentrated in the tail and have reduced limbs, which are folded against the body in fast swimming.

Many animals, principally invertebrates and certain fishes, achieve locomotion by contact with the substrate. In fast-moving or turbulent water the animal usually has one or more adhesive disks for attachment to the substrate. In calmer water animals such as lobsters usually walk on the bottom.

aquatint, a variety of etching widely used by printmakers to achieve a broad range of tonal values. The process is called aquatint because finished prints often resemble water-colour drawings or wash drawings. The technique consists of exposing a copperplate to acid through a layer of granulated resin or sugar. The acid bites away the plate only in the interstices between the resin or sugar grains, leaving an evenly pitted surface that yields broad areas of tone when the grains are removed and the plate is printed. An infinite number of tones can be achieved by exposing various parts of the plate to acid baths of different strengths for different periods of time. Etched or engraved lines are often used with aquatint to achieve greater definition of form.

In the 17th century a number of attempts were made at producing what later became known as aquatint prints. None of the efforts was successful, however, until 1768, when the French printmaker Jean-Baptiste Le Prince discovered that granulated resin gave satisfactory results. Aquatint became the most popular method of producing toned prints in the late 18th century, especially among illustrators. Its textural subtleties, however, remained largely unexplored by well-known artists except for Francisco de Goya. Most of his prints are aquatints, and he is considered the greatest master of the technique.

After Goya's death aquatint was largely ignored until Edgar Degas (1834–1917) and Camille Pissarro (1830–1903) began to experiment with it. After a century of neglect, sugar aquatint, sometimes called sugar lift, was re-

"Por que fue sensible," aquatint by Francisco de Goya from "Los Caprichos," 1799

By courtesy of Mrs Geoffrey Wilson and Courtauld Institute of Art London

vived by 20th-century artists such as Pablo Picasso and Georges Rouault. Many contemporary printmakers also use pressurized plastic sprays in place of resin.

aquavit, also spelled AQUAVITE, or AKVAVIT, also called SNAPS, flavoured, distilled liquor, clear to pale yellow in colour, dry in flavour, and ranging in alcohol content from about 42 to 45 percent by volume. It is distilled from a fermented potato or grain mash, redistilled in the presence of flavouring agents, filtered with charcoal, and usually bottled without aging. Various aromatic flavourings are employed, usually including caraway or cumin seed; lemon or orange peel, cardamom, aniseed, and fennel also may be used.

The beverage, produced in the Scandinavian countries, derives its name from *aqua vitae* (Latin: "water of life"), applied originally to liquor distilled from wine, and was made from imported wine; the product therefore was highly expensive until Swedish soldiers learned to make aquavit from grain. In the 18th century the potato became an important raw material.

Swedish and Norwegian aquavits are sweet and spicy and of straw colour. Sweden is the largest producer, manufacturing about 20 brands. Norway's production, comparatively low, includes Linie Aquavit, so called because it is shipped to Australia and back (across the Equator, or Line) in oak containers to produce mellow flavour. Finnish aquavit has a cinnamon flavour. The Danish product, also called *snaps*, is colourless, with a pronounced caraway flavour. One of the best known Danish types is Alborg akvavit, named for a small town in Jutland, on Denmark's northern coast. The only brand exported from Denmark, it is produced by Danish Distilleries, a private organization granted the sole right to produce alcohol and yeast since 1927 under a monopoly of the Danish government.

In both the Scandinavian countries and northern Germany, aquavit is usually served chilled and unmixed, in small glasses, and is usually accompanied by appetizers or sandwiches; it is the traditional accompaniment to a smorgasbord.

Aquaviva, Claudio, Aquaviva also spelled ACQUAVIVA (b. Sept. 14, 1543, Atri, Kingdom of Naples—d. Jan. 31, 1615, Rome), fifth

and youngest general of the Society of Jesus, considered by many to have been the order's greatest leader. The youngest son of the Duke of Atri, he joined the order in 1567. Shortly after completing his studies he was appointed provincial superior of Naples and then of Rome.

He was elected general in 1581, and his major political achievement occurred at the Jesuits' fifth General Congregation (1593–94). He succeeded in overcoming the efforts of some Spanish Jesuits—supported at first by King Philip II of Spain—to introduce modifications in the Institute of the Society of Jesus and to obtain a privileged status for the Spanish provinces.

Aquaviva's rule was marked by the rapid growth of the order from about 5,000 to more than 13,000 members and from 21 to 32 provinces, with the number of colleges reaching 372. His practical legislation strengthened the society and made it more efficient in its numerous foreign missions and colleges. He promoted the use of the *Spiritual Exercises* of St. Ignatius Loyola for the clergy and laymen. He encouraged the order's theologians and spiritual writers to more profound investigation and to publication. He organized the first scholarly writing of the history of the order and the compilation of annual reports of all the provinces (*Litterae Annuae*).

In the Constitutions of the order, Ignatius had indicated only in outline the Jesuit system of education. The fourth General Congregation, which had elected Aquaviva general, entrusted him with the task of drawing up a practical code of education for its schools. This work, *Ratio atque institutio studiorum* ("The Reason and Establishment of Studies"), was first published in 1586, at which time it was distributed to Jesuit schools for criticism and revision. The definitive text (1599) unified Jesuit teaching throughout the world, yet allowed for adaptation to local needs. His work strengthened the order internally and guided its external relations. He successfully furthered the apostolate of the Roman Catholic Church under eight popes, from Gregory XIII to Paul V.

aqueduct, man-made conduit for carrying water (Latin *aqua*, "water," and *ducere*, "to lead"). In a more restricted sense, aqueducts are structures used to conduct a water stream across a hollow or valley. In modern engineering "aqueduct" refers to a system of pipes, ditches, canals, tunnels, and supporting structures used to convey water from its source to its main distribution point.

A brief treatment of aqueducts follows. For full treatment, see MACROPAEDIA: Public Works.

Although the Romans are considered the greatest aqueduct builders of the ancient world, *qanat* systems were in use in ancient Persia, India, Egypt, and other Middle Eastern countries hundreds of years earlier. These systems utilized tunnels tapped into hillsides that brought water for irrigation to the plains below. Somewhat closer in appearance to the classic Roman structure was a limestone aqueduct built by the Assyrians around 691 BC to bring fresh water to the city of Nineveh. Approximately 2,000,000 large blocks were used to make a water channel 30 feet (10 metres) high and 900 feet long across a valley.

The elaborate system that served the capital of the Roman Empire, however, remains a major engineering achievement. Over a period

of 500 years—from 312 BC to AD 226—11 aqueducts were built to bring water to Rome from as far away as 57 miles (92 kilometres). Some of these aqueducts are still in use. Only a portion of Rome's aqueduct system actually crossed over valleys on stone arches (30 mi out of a total of about 260 mi); the rest consisted of underground conduits made mostly of stone and terra cotta pipe but also of wood, leather, lead, and bronze. Water flowed to the city by the force of gravity alone and usually went through a series of distribution tanks within the city. Generally water was not stored, and the excess was used to flush out sewers. Rome's famous fountains were also supplied in this way.

Roman aqueducts were built throughout the empire, and their arches may still be seen in Greece, Italy, France, Spain, North Africa, and Asia Minor. As central authority fell apart in the 4th and 5th centuries, the systems also deteriorated. For most of the Middle Ages aqueducts were not used in western Europe, and people returned to getting their water from wells and local rivers. Modest systems sprang up around monasteries, and, by the 14th century, Bruges, with a large population for the time (40,000), had developed a system utilizing one large collecting cistern from which water was pumped, using a wheel with buckets on a chain, through underground conduits to public sites.

Major advances in public-water systems since the Renaissance have involved the refinement of pumps and of pipe materials. By the late 16th century London had a system that used five waterwheel pumps fastened under the London Bridge to supply the city, and Paris had a similar device at Pont Neuf that was capable of delivering 120 gallons (454 litres) per minute. Both cities were compelled to bring water from greater distances in the next century. A private company built an aqueduct to London from the river Chadwell, some 38 mi distant, that utilized more than 200 small bridges built of timber. A French counterpart combined pumps and aqueducts to bring water from Marly over a ridge and into an aqueduct some 525 ft above the Seine.

One of the major innovations during the 18th and 19th centuries was the introduction of steam pumps and the improvement of pressurized systems. One benefit of pumping water under pressure was that a system could be built that followed the contours of the land; the earlier free-flowing systems had had to maintain certain gradients over varied terrain. Pressurization also created the need for better pipe material. Wood pipes banded with metal and protected with asphalt coating were patented in the United States in 1855 and could withstand pressures up to 172 pounds per square inch (12 kilograms per square centimetre). Before long, however, wood was replaced first by cast iron and then by steel. For large siphons (conduits that draw water from elevated sources under the pressure of siphoning), reinforced concrete became the preferred construction material early in the 20th century.

Modern aqueducts, although lacking the arched grandeur of those built by the Romans, greatly surpass the earlier ones in length and in the amount of water that they can carry. Aqueduct systems hundreds of miles long have been built to supply growing urban areas and crop-irrigation projects. The water supply of New York City comes from three main aqueduct systems that can deliver from 1,800,000,000 gal of water a day from sources up to 120 mi away. The aqueduct system in the state of California, however, is by far the largest in the world. One major project, which has been under construction since 1960, will eventually bring water from the northern part

of the state some 600 mi south to the Mexican border and is designed to yield 4,230,000 acre-feet (one acre-foot equals 325,851 gallons) per year.

Aquem-os-Montes (Portugal): see Minho.

Aquen, Jerome van: see Bosch, Hiëronymus.

aqueous humour, watery, alkaline liquid that occupies the anterior and posterior chambers of the eye—the space in front of the iris and lens and the ringlike space encircling the lens. The aqueous humour resembles blood plasma in composition, but contains much less protein, less glucose, more lactic acid, and much more ascorbic acid. Aqueous humour is formed from the blood by filtration through the surface of the back of the iris and of the ciliary body, the muscular structure that controls the curvature of the lens. It leaves the eye through a porous tissue into Schlemm's canal, a ringlike passageway around the outer angle of the anterior chamber. From the canal the liquid enters the veins.

When the aqueous humour does not adequately drain from the eye, pressure builds up and glaucoma can result.

Aquidneck Island (Rhode Island, U.S.): see Rhode Island.

aquifer, in hydrology, rock layer that contains water and releases it in appreciable amounts. The rock contains water-filled pore spaces, and, when the spaces are connected, the water is able to flow through the matrix of the rock. An aquifer also may be called a water-bearing stratum, lens, or zone.

A confined aquifer is a water-bearing stratum that is confined or overlain by a rock layer that does not transmit water in any appreciable amount or that is impermeable. There probably are few truly confined aquifers, because tests have shown that the confining strata, or layers, although they do not readily transmit water, over a period of time contribute large quantities of water by slow leakage to supplement production from the principal aquifer.

A groundwater aquifer is said to be unconfined when its upper surface (water table) is open to the atmosphere through permeable material. As opposed to a confined aquifer, the water table in an unconfined aquifer system has no overlying impervious rock layer to separate it from the atmosphere.

Aquifoliaceae, the holly family, in the order Celastrales, found worldwide, comprising two genera and about 400 species of shrubs and trees, best known for the genus *Ilex* (see holly). Four species of *Byronia* are in the Polynesian and Australian area, and only one species of mountain holly (*Nemopanthus mucronatus*) is native to northeastern North America.

The Aquifoliaceae differ from other members of the order Celastrales in lacking a nectar-secreting disk in the flowers.

Aquila, also called AKILAS (fl. 2nd century AD), scholar who in about AD 140 completed a literal translation into Greek of the Old Testament; it replaced the Septuagint (*q.v.*) among Jews and was used by the Church Fathers Origen in the 3rd century and St. Jerome in the 4th and 5th centuries. St. Epiphanius (*c.* 315—403) preserved in his writings the popular Christian tradition that Aquila was a relative of the Roman emperor Hadrian, who employed him in rebuilding Jerusalem. There he was converted to Christianity, but, on being reproved for practicing pagan astrology, he returned to Judaism.

The Talmud, the rabbinic compendium of law, lore, and commentary, states that Aquila was influenced in his translation by the great martyred scholar Rabbi Akiba ben Joseph (*q.v.*).

Aquila's version survives only in fragments, chiefly in extant portions of Origen's *Hexapla*

and in manuscripts found in the *geniza* (synagogue storeroom for books) at the Ezra synagogue in Cairo. Aquila's exacting translation is important for what it reveals of the original Hebrew text of the Bible and also for what it demonstrates about the state of Hebrew learning in his time.

Aquila, L' (Italy): see L'Aquila.

Aquileia, formerly a city of the Roman Empire and a patriarchate of the Roman Catholic Church; it is now a village in Udine province of the Friuli-Venezia Giulia region in northeastern Italy, on the Natisone River near the Adriatic coast, northwest of Trieste.

Founded as a Roman colony in 181 BC to prevent barbarian incursions, Aquileia's position at the junction of the Via Postumia with roads north and east to the Roman provinces of Illyria, Pannonia, and Noricum encouraged its rapid growth as a commercial as well as military centre. By the 4th century it had become capital of the administrative regions of

The Basilica Teodoriana, Aquileia, Italy
Shostal—EB Inc

Venetia and Istria. Although the city had been unsuccessfully besieged by the Marcomanni and the Quadi (Germanic tribes) in 167, it fell to the Huns and was sacked in 452. The Lombards' invasion of Italy in 568 and their conquest of the Venetian mainland marked the final eclipse of Aquileia's political and economic importance; it became part of the Lombard duchy of Friuli.

An episcopal see (according to tradition, founded by St. Mark) from about the middle of the 3rd century, Aquileia became in the 5th century the metropolitan see for Venetia and Istria as well as for the outlying region north and east. After the condemnation in 533 by Pope Vigilius of the Three Chapters (heretical writings based on the emperor Justinian's ecclesiastical policies), Aquileia seceded from Rome, its bishop Macedonius adopting the title of patriarch in defiance of the Pope. The see remained schismatic when the patriarch Paolino I fled to Grado (the earlier foreport of Aquileia) after the Lombard invasion. When Candianus, who was loyal to Rome, was elected metropolitan at Grado in 607, the suffragan bishops of the Lombard mainland elected an abbot, John, at Aquileia, and he continued the schismatic policy of his predecessors.

The schism was finally ended under the pontificate of Sergius I (687–701) at a council at Pavia. Henceforth, Aquileia and Grado were recognized as separate sees and patriarchates. The residence of the patriarch of Aquileia had been transferred to Cormons in 627 for reasons of safety and to Cividale in 730. Aquileia's ecclesiastical importance was much enhanced by the mission of Bishop Paolino II (died 802) to the Avars and Slovenes, and in the 11th century Aquileia acquired extensive political privileges and feudal dominions, largely from the German kings. Bishop Poppone, who built Aquileia's Basilica Teodoriana (1021–31), was granted the right to coin money, and the see was invested with the county of Friuli and

the marches (frontier territories) of Carniola (1077) and Istria (1209).

It remained a feudal principality until the conquest of Friuli by Venice in 1419–20. By the treaty of 1445, the patriarch finally acquiesced in the Venetian conquest and retained only Aquileia itself, San Vito, and San Daniele del Friuli. From the 15th century, the patriarchs were always Venetians. In 1751 Pope Benedict XIV suppressed the patriarchate and created the archbishoprics of Udine and Gorizia in its place. Aquileia, with its cathedral, was placed under papal jurisdiction. Pop. (1990 est.) mun., 3,451.

Aquinas, Saint Thomas: see Thomas Aquinas, Saint.

Aquino, ancient (Latin) AQUINUM, town, Frosinone *provincia*, Lazio *regione*, south-central Italy, southeast of Frosinone city. The ancient town (the site of which is nearby) prospered from its position on the Roman road, Via Latina, until it was laid waste by Totila, a Gothic king, in the mid-6th century and abandoned for the more fertile present site. During the feudal struggles Riccardo, count of Acerra and uncle of St. Thomas Aquinas, was an important figure there. Roman ruins at the site include a temple, an amphitheatre, and a triumphal arch supposed to honour the general and triumvir Mark Antony. Aquino is on the railway between Rome and Naples, and agriculture is the chief occupation. There is a sulfur and iron spring. Pop. (1990 est.) mun., 5,396.

Aquino, Benigno Simeon, Jr., byname NI-NOY (b. Nov. 27, 1932, Tarlac, Phil.—d. Aug. 21, 1983, Manila), the chief opposition leader during the era of martial law in the Philippines (1972–81) under President Ferdinand E. Marcos. Aquino's assassination in 1983 galvanized popular opposition to the Marcos government and brought his widow, Corazon, to the political forefront.

The grandson of a Philippine general and the son of a well-known politician and landowner, Aquino began his career as a journalist and then was elected mayor of Concepción in 1955, vice-governor of Tarlac province in 1959, governor of Tarlac province in 1961, Philippine senator in 1967, and national leader of the Liberal Party in 1968. Meanwhile, he had become wealthy through his marriage (1955) to the daughter of one of the largest landowners and manufacturers in the country.

Ostensibly planning to run for president in 1973, Aquino was thwarted in 1972 when President Marcos declared martial law; he spent the next eight years in prison, being sentenced to death in November 1977. In 1980 Marcos commuted the death sentence and allowed Aquino to go to the United States for heart-bypass surgery. Aquino remained there with his family for three years, receiving research grants from Harvard University and the Massachusetts Institute of Technology. Two years after martial law was lifted in the Philippines, he flew home, intending to campaign in promised elections. He was shot in the head while leaving the airplane at Manila Airport under security guard.

Aquino's death sparked widespread demonstrations charging government complicity in the act. An independent commission concluded in October 1984 that a military conspiracy led by the Philippine armed forces chief of staff, General Fabian C. Ver, was responsible for the assassination. Ver and 25 other suspected participants in the plot were acquitted of these charges by three Marcos-appointed judges in 1985.

Aquino, Corazon, in full MARIA CORAZON AQUINO, *née* COJUANGCO, byname CORY AQUINO (b. Jan. 25, 1933, Manila, Phil.), political leader (from 1983) and president (1986–92) of the Philippines.

Corazon Cojuangco was born into a wealthy,

politically prominent family based in Tarlac province, north of Manila. She graduated from Mount St. Vincent College in New York City in 1954 but abandoned further studies in 1955 to marry Benigno Simeon Aquino, Jr., who was then a promising young politician. Corazon remained in the background during her husband's subsequent career, rearing their five children at home and later in exile. Her husband was assassinated upon his return to the Philippines in August 1983.

When Ferdinand E. Marcos unexpectedly called for presidential elections in February 1986, Corazon Aquino became the unified opposition's presidential candidate. Though she was officially reported to have lost the election to Marcos, Aquino and her supporters challenged the results, charging widespread voting fraud. High officials in the Philippine military soon publicly renounced Marcos' continued rule and proclaimed Aquino the Philippines' rightful president. On Feb. 25, 1986, both Aquino and Marcos were inaugurated as president by their respective supporters, but that same day Marcos fled the country.

In March 1986 she proclaimed a provisional constitution and soon thereafter appointed a commission to write a new constitution. The resulting document was ratified by a landslide popular vote in February 1987. During her term of office, however, her popularity steadily declined as she faced continual outcries over economic injustice and political corruption, problems that were exacerbated by persistent warfare between the communist insurgency and a military whose loyalties to Aquino were uncertain. In general, her economic policies were criticized for being mixed or faltering in the face of mass poverty.

Aquitaine, *région* encompassing the *départements* of Dordogne, Gironde, Landes, Lot-et-Garonne, and Pyrénées-Atlantiques in southwestern France. It is roughly coextensive with the western half of the historical region of Aquitaine. The capital is Bordeaux.

In Julius Caesar's description of Gaul, "Aquitania" was an area extending from the Pyrenees to the Garonne River. The Roman emperor Augustus (reigned 27 BC–AD 14) made it a Roman administrative district, and its borders were extended as far north as the Loire River and east to the Massif Central.

A Visigothic province in the 5th century, Aquitaine came under Frankish rule in the 6th century, retaining a measure of provincial identity exploited by local rulers. Long resistant in the 8th century, it was finally subdued by Charlemagne, who bestowed it (less Gascony) as a kingdom upon his son Louis (the future emperor Louis I). It remained a kingdom under Louis's son Pepin I and the latter's son Pepin II, its chief towns being Toulouse, Limoges, and Poitiers. Devastation by the Normans in the 9th century resulted in political and social upheavals during the course of which various feudal domains were established.

The title of duke of Aquitaine, which had already been used by various little-known persons in the 7th century, was assumed at the end of the 9th by William I the Pious, count of Auvergne, the founder of the Abbey of Cluny. In the first half of the 10th century the counts of Auvergne, of Toulouse, and of Poitiers each claimed this ducal title, but it was eventually secured by William I, count of Poitiers (William III of Aquitaine). The powerful house of the counts of Poitiers retained Aquitaine during the 10th and 11th centuries, endeavouring from time to time to restore to the name its former significance by extending the boundaries of the duchy to include Gascony and Toulouse. Then, on the death without heirs of the last duke, William X (William VIII of Poitiers), in 1137, his daughter Eleanor united Aquitaine to the kingdom of France by her marriage with Louis VII. When Louis

divorced her, however, Eleanor of Aquitaine married in 1152 the count of Anjou, Henry Plantagenet, who two years later became king of England as Henry II. The duchy thus passed to her new husband, who, having suppressed a revolt there, gave it to his son, Richard the Lion-Heart (later Richard I of England), who spent most of his life in Aquitaine, often subduing rebellious vassals. When Richard died

The Roman province of Aquitaine

Adapted from Westermann *Grosser Atlas zur Weltgeschichte*, Georg Westermann Verlag Braunschweig

in 1199, the duchy reverted to Eleanor, and, on her death five years later, it was united to the English crown and henceforward followed the fortunes of the English possessions in France.

Aquitaine, as it came to the English kings, stretched as of old from the Loire to the Pyrenees, but its extent was curtailed on the southeast by the wide lands of the counts of Toulouse. The name Guyenne (or Guienne), a corruption of Aquitaine, seems to have come into use about the 10th century, and the subsequent history of Aquitaine is merged in that of Gascony and Guyenne (*qq.v.*), which were completely reunited to France by the end of the Hundred Years' War.

Lowlands predominate in Aquitaine outside the Pyrenees mountains themselves, which rise in the south. The highest point in the region is the peak of Midi d'Ossau (9,465 feet [2,885 m]); most land, however, lies below 1,600 feet. Annual precipitation exceeds 30 inches (800 mm) outside Lot-et-Garonne and southern Dordogne and increases toward the Pyrenees. An oceanic climate prevails. The population of the Aquitaine region is increasingly urban, and small towns are generally in decline. Corn (maize) was introduced into Aquitaine in the late 16th century and has become the leading cereal. Viticulture is widespread. Cash crops were introduced in the late 19th century and include tobacco, apples, pears, peaches, French beans, and peas. Forests cover much of the land. The industrial sector is of little importance outside Bordeaux. Area 15,949 square miles (41,309 square km). Pop. (1990) 2,796,093.

AR-15 (rifle): see M16 rifle.

Ara, also spelled ARRAH, city, Bihār state, northeastern India. The city is a major rail and road junction. Agricultural trade and oilseed milling are carried on there. It is the site of several colleges affiliated with Magadh University. The Little House at Ara is a building that was defended by the British against Kunwar Singh during the Indian Mutiny in 1857. Ara was constituted a municipality in 1865. Pop. (1991 prelim.) 156,871.

Ara Pacis, also called ARA PACIS AUGUSTAE (Latin: "Altar of the Augustan Peace"), shrine

consisting of a marble altar in a walled enclosure erected in Rome's Campus Martius by the emperor Augustus and dedicated on Jan. 30, 9 BC. The sculptures on the walls and the altar representing the shrine's dedication ceremonies, scenes from Roman legend, and floral motifs are considered to be among the finest examples of Roman art.

Arab, Arabic singular masculine 'ARABI, singular feminine 'ARABIYAH, plural 'ARAB, one whose native language is Arabic. (See Arabic language.) Before the spread of Islām and, with it, the Arabic language, "Arab" referred to any of the largely nomadic Semitic inhabitants of the Arabian Peninsula. In modern usage, it embraces any of the Arabic-speaking peoples living in the vast region from Mauritania, on the Atlantic coast of Africa, to southwestern Iran, including the entire Maghrib of North Africa, Egypt and The Sudan, the Arabian Peninsula, and Syria and Iraq.

This diverse assortment of peoples defies physical stereotyping. Most Arabic-speaking peoples are of the European (Caucasoid) geographic race, but there is considerable regional variation. The early Arabs of the Arabian Peninsula were predominantly nomadic pastoralists who herded their sheep, goats, and camels through the harsh desert environment. Settled Arabs practiced date and cereal agriculture in the oases, which also served as trade centres for the caravans transporting the spices, ivory, and gold of southern Arabia and the Horn of Africa to the civilizations farther north. The distinction between the desert nomads, on the one hand, and town dwellers and agriculturists, on the other, still pervades much of the Arab world.

Islām, which developed in the west-central Arabian Peninsula in the early 7th century AD, was the religious force that unified the desert subsistence nomads—the Bedouins—with the town dwellers of the oases. Within a century, Islām spread throughout most of the present-day Arabic-speaking world, and beyond, from Central Asia to the Iberian Peninsula. Arabic, the language of the Islāmic sacred scripture (the Qur'ān), was adopted throughout much of the Middle East and North Africa as a result of the rapidly established supremacy of Islām in those regions. Other elements of Arab culture, including the veneration of the desert nomad's life, were integrated with many local traditions. Arabs of today, however, are not exclusively Muslim; approximately 5 percent of the native speakers of Arabic worldwide are Christians, Druzes, Jews, or animists.

Traditional Arab values were modified in the 20th century by the pressures of urbanization, industrialization, detribalization, and Western influence. Nearly half of Muslim Arabs live in cities and towns, where family and tribal ties tend to break down, where women, as well as men, have greater educational and employment opportunity, and where the newly emerging middle class of technicians, professionals, and bureaucrats has gained influence.

The majority of Arabs continue to live in small, isolated farming villages, where traditional values and occupations prevail, including the subservience and home seclusion of women. While urban Arabs tend to identify themselves more by nationality than by tribe, village farmers venerate the pastoral nomad's way of life and claim kinship ties with the great desert tribes of the past and present. Nationalism and the change in standards of living that have been made possible by the expanded oil industry, however, have radically altered the nomadic life.

The pastoral desert nomad, the traditional ideal of Arab culture, makes up barely 5 percent of the modern Arab population. Many of the remaining nomads have given up full-

time subsistence pastoralism to become village agriculturists or stock breeders, or to find employment with oil companies or other employers in the towns and cities.

'**Arab, Shaṭṭ Al-** (Arabic: "Stream of the Arabs"), river in southeastern Iraq, formed by the confluence of the Tigris and Euphrates rivers at the town of Al-Qurnah. It flows south-eastward for 120 miles (193 km) and passes the Iraqi port of Basra and the Iranian port of Abadan before emptying into the Persian Gulf. For about the last half of its course the river forms the border between Iraq and Iran; it receives a tributary, the Kārūn River, from the eastern (Iranian) side. Its width increases from about 120 feet (37 m) at Basra to 0.5 mile (0.8 km) at its mouth. Along the settled banks there are date-palm groves, which are naturally irrigated by tidal action. The Kārūn empties large quantities of silt into the Shaṭṭ Al-'Arab, necessitating continuous dredging to keep the channel navigable for shallow-draft oceangoing vessels. In the 1980s the Shaṭṭ Al-'Arab was the scene of prolonged and intense fighting between Iraq and Iran; the former had invaded the latter in 1980 after asserting Iraqi sovereignty over both banks of the river.

Arab Bank for Economic Development in Africa, French BANQUE ARABE POUR LE DÉVELOPPEMENT ÉCONOMIQUE EN AFRIQUE (BADEA), Arabic AL-BANK AL-'ARABĪ LIL-TAṬAWŪR AL-IQTISĀDĪ FĪ AFRĪQIYĀ, bank created by the Arab League summit conference in Algiers, in November 1973, to finance development projects. In 1975 BADEA began operating by supplying African countries with technical assistance. All members of the Organization of African Unity (OAU) are eligible as recipients, except those countries belonging to the Arab League. BADEA includes all members of the Arab League except the Comoros, Djibouti, Somalia, and Yemen. The objectives of BADEA are twofold: to assist African countries with large balance-of-payment deficits by providing aid and to sponsor Arab investments in Africa through investment guarantees. The headquarters are located in Khartoum, The Sudan.

Arab Economic Unity, Council of, Arabic AL-JAM'ĪYAH AL-'ARABĪYAH LIL-WIḤDAH AL-IQTISĀDĪYAH, Arab organization established in June 1957 by a resolution of the Arab Economic Council of the Arab League. The first meeting of the council was held in 1964. Membership is composed of Egypt, Iraq, Jordan, Kuwait, Libya, Mauritania, the Palestine Liberation Organization, Somalia, The Sudan, Syria, United Arab Emirates, and Yemen.

The council's focus is regional, devoted to achieving economic integration through the framework of economic and social development. An agreement within the council established (1964) the Arab Common Market between Iraq, Jordan, Egypt, and Syria, later joined by Libya, Mauritania, and Yemen; its members facilitate the international movement of capital, goods, and people.

Arab Fund for Economic and Social Development, Arabic AṢ-ṢANDŪQ AL-'ARABĪ LIL-ISTITHMĀR WA AT-TANMĪYAH AL-IJTIMĀ'ĪYAH, Arab League fund designed to promote economic and social development of Arab countries. Established in May 1968, the fund commenced operations in 1972 and serves 20 Arab countries and the Palestine Liberation Organization.

By financing development projects, the fund encourages investment of public and private capital in Arab economies. Headquarters are in Safat, Kuwait.

Arab-Israeli wars, major conflicts between Israeli and various Arab forces, most notably in 1948–49, 1956, 1967, 1973, and 1982.

The first war immediately followed the proclamation of the State of Israel, May 14,

1948. Arab forces from Egypt, Transjordan, Iraq, Syria, and Lebanon occupied the areas in southern and eastern Palestine not apportioned to the Jews, then captured the small Jewish quarter of the Old City of Jerusalem. The Israelis, meanwhile, won control of the main road to Jerusalem through the Yehuda Mountains (Judaeen Hills) and successfully beat off Arab attacks. By early 1949 the Israelis managed to occupy all of the Negev up to the former Egypt-Palestine frontier, except for the Gaza Strip. Between February and July 1949, as a result of separate armistice agreements between Israel and the Arab states, a temporary frontier was fixed where the line had been at the beginning of the negotiations.

Tensions mounted again with the rise to power of the nationalist Egyptian president Gamal Abdel Nasser; in October 1956, in the midst of the international crisis caused by Nasser's seizure of the European-owned Suez Canal, Israel invaded the Sinai Peninsula to destroy Arab military bases there. In five days the Israeli army captured Gaza, Rafah, and Al-'Arish—taking thousands of prisoners—and occupied most of the peninsula east of the Suez Canal. The Israelis were then in a position to open sea communications through the Gulf of Aqaba, an added threat to the Egyptians. In December, after a joint Anglo-French intervention, a United Nations (UN) Emergency Force was stationed in the area, and Israeli forces withdrew in March 1957.

Arab and Israeli forces clashed for the third time June 5–10, 1967, in what came to be called the Six-Day War. In early 1967 Syrian bombardments of Israeli villages had been intensified. When the Israeli Air Force shot down six Syrian MiG planes in reprisal, Nasser mobilized his forces near the Sinai border. During this war Israel eliminated the Egyptian air force and established air superiority. The war cost the Arabs the Old City of Jerusalem, the Sinai and the Gaza Strip, the Jordanian territory west of the Jordan River known as the West Bank, and the Golan Heights, on the Israeli-Syrian border.

The sporadic fighting that followed the Six-Day War again developed into full-scale war in 1973. On October 6, the Jewish holy day of Yom Kippur (thus "Yom Kippur War"), Israel was attacked by Egypt across the Suez Canal and by Syria on the Golan Heights. The Arab armies showed greater aggressiveness and fighting ability than in the previous wars, and the Israeli forces suffered heavy casualties. The Israeli army, however, pushed its way into Syrian territory and encircled the Egyptian Third Army by crossing the Suez Canal and establishing forces on its west bank.

Israel and Egypt signed a cease-fire agreement in November and, on Jan. 18, 1974, peace agreements. The accords provided for Israeli withdrawal into the Sinai west of the Mitla and Gidi passes, while Egypt was to reduce the size of its forces on the east bank of the canal. On May 31, 1974, Israel and Syria signed a cease-fire agreement that also covered separation of their forces by a UN buffer zone and exchange of prisoners of war.

On March 26, 1979, Israel and Egypt signed a peace treaty that formally ended the state of war that had existed between the two countries for 30 years. Under the terms of the Camp David Accords, as the treaty was called, Israel returned the entire Sinai Peninsula to Egypt, and, in return, Egypt recognized Israel's right to exist. The two nations subsequently established normal diplomatic relations with each other.

On June 5, 1982, less than six weeks after Israel's complete withdrawal from the Sinai, increased tensions between Israelis and Palestinians resulted in the Israeli jet bombings of Beirut and southern Lebanon, where the Palestine Liberation Organization (PLO) had a number of strongholds. By June 14 Israel's land forces had invaded Lebanon as far as

the outskirts of Beirut, which was encircled; but the Israeli government agreed to halt the advance and begin negotiations with the PLO. After much delay and massive Israeli shelling of West Beirut, the PLO evacuated the city under the supervision of a multinational force. Eventually, Israeli troops withdrew from West Beirut, and the Israeli army had withdrawn entirely from Lebanon by June 1985.

Hostility continued, however. On December 9, 1987, rioting broke out among Palestinian Arabs living in the Israeli-occupied territories of the Gaza Strip and the West Bank and in Jerusalem. The Palestinian demonstrations and riots continued in the following years and took on the character of a mass popular rebellion (known as the *intifada*, or "uprising") directed against continued Israeli occupation of the West Bank and the Gaza Strip. In 1993 Israel and the PLO reached an agreement that involved mutual recognition and envisaged the gradual implementation of Palestinian self-government in the West Bank and Gaza Strip before a permanent peace settlement. That process began in 1995.

Arab League, also called LEAGUE OF ARAB STATES (LAS), Arabic AL-JĀMI'Ā AL-'ARABIYAH, or AL-JĀMI'Ā AD-DUWAL AL-'ARABIYAH, regional organization of Arab states in the Middle East, formed in Cairo on March 22, 1945. The founding member states were Egypt, Syria, Lebanon, Iraq, Transjordan (now Jordan), Saudi Arabia, and Yemen. Other members are Libya (1953); The Sudan (1956); Tunisia and Morocco (1958); Kuwait (1961); Algeria (1962); Bahrain, Oman, Qatar, and the United Arab Emirates (1971); Mauritania (1973); Somalia (1974); the Palestine Liberation Organization (PLO; 1976); Djibouti (1977); and the Comoros (1993).

The aims of the league in 1945 were to strengthen and coordinate the political, cultural, economic, and social programs of its members and to mediate disputes among them or between them and third parties. The signing on April 13, 1950, of an agreement on joint defense and economic cooperation also committed the signatories to coordination of military defense measures.

In its early years, the Arab League concentrated mainly on economic, cultural, and social programs. In 1959 it held the first Arab petroleum congress and in 1964 established the Arab League Educational, Cultural and Scientific Organization (ALECSO). Also in

1964, despite objections by Jordan, the league admitted the PLO as the representative of all Palestinians. Under the leadership of Mahmoud Riad, the third secretary-general (1972–79), political activity increased. The league, however, was weakened by internal dissension on political issues, especially those concerning Israel and the Palestinians. After Egypt signed a peace treaty with Israel on March 26, 1979, the other members of the Arab League voted to suspend Egypt's membership and to transfer the league's headquarters from Cairo to Tunis. Egypt was reinstated as a member of the Arab League in 1989, and the league's headquarters returned to Cairo in 1990.

The Iraqi invasion of Kuwait in 1990 and the later involvement, at the request of Saudi Arabia, of Western countries—mainly the United States—in ridding Kuwait of Iraqi presence caused a deep rift in the league. Saudi Arabia, Egypt, Syria, Morocco, Qatar, Bahrain, Kuwait, the United Arab Emirates, Lebanon, Djibouti, and Somalia endorsed the presence of foreign troops in Saudi Arabia, and all but the last three had some degree (however slight) of military involvement in the war.

Arab Legion, Arabic AL-JAIŠH AL-'ARABI, police force raised in 1921 by British Lieutenant Colonel Frederick Gerard Peake in what was then the British protectorate of Transjordan, to keep order among Transjordanian tribes and to safeguard Transjordanian villagers from Bedouins. In 1939 Major (later General) John Bagot Glubb, called Glubb Pasha, became the legion's commander and transformed it into the most effective military force in the Arab world. At the end of the first Arab-Israeli war (1949), the Arab Legion, 6,000 strong, was the only Arab army that had been able to retain any Palestinian territory against the Israelis.

Even after Jordan proclaimed its independence from Britain, the Arab Legion remained under Glubb's command, but nationalist sentiments in the country grew until King Hussein, who came into power in 1953, was forced to dismiss Glubb on March 1, 1956. The legion, which was a volunteer army, merged with the Jordanian National Guard, a conscripted force, to form a unified Jordanian army.

Arab Monetary Fund, Arabic AŞ-SANDŪQ AL-MĀLI AL-'ARABI, fund that aims to assist its participants, nearly all of the members of the Arab League, by developing their capital mar-

kets, balancing payment difficulties, and helping with foreign-exchange rates. Established in April 1976, the agreement entered into force in February 1977. During its annual meeting, the board of governors of the fund formulates policy aimed at integrating and liberalizing trade. The headquarters are in Abu Dhabi, United Arab Emirates.

Arab Petroleum Exporting Countries, Organization of (OPEC), Arabic MUNAẒAMAT AD-DŪWAL AL-'ARABIYAH AL-MUŞADDARAH LIL-BITRŪL, Arab organization formed in January 1968 to promote international economic cooperation within the petroleum industry. Member countries include Algeria, Bahrain, Egypt, Iraq, Kuwait, Libya, Qatar, Saudi Arabia, Syria, and the United Arab Emirates. The headquarters are in Kuwait.

OPEC seeks to achieve four basic goals. These include realizing close national ties, determining ways and means of safeguarding member interests, unifying efforts to maintain a flow of petroleum to markets on profitable terms, and creating a suitable climate for industry investment in member countries.

Arab Socialist Renaissance Party: see Ba'ath Party.

'Arabah, Wadi Al-, Hebrew HA-'ARAVA, topographic depression in southern Palestine extending about 100 miles (160 km) south from the Dead Sea to the Gulf of Aqaba; it is part of the East African Rift System. Largely sandy desert, it is divided between Israel and Jordan. In the Old Testament, except in Deuteronomy 2:8, the name Al-'Arabah refers to the Jordan Valley, but eventually the name came to be applied exclusively to the southern area. As the site of important trade routes and the only iron and copper mines in Canaan, Al-'Arabah was frequently fought over in biblical times by the kings of Judah and Edom.

arabesque, style of decoration characterized by intertwining plants and abstract curvilinear motifs. Derived from the work of Hellenistic craftsmen working in Asia Minor, the arabesque originally included birds in a highly naturalistic setting. As adapted by Muslim artisans about AD 1000, it became highly formalized; for religious reasons, no birds, beasts, or human figures were included. The arabesque

Borders of Israel and Occupied Territories

became an essential part of the decorative tradition of Islāmic cultures.

In Europe from the Renaissance until the early 19th century, arabesques were used for

Arabesque decoration on the dome of the Madar-i-Shāh *madrasah* ("school") built by Ḥusayn I, early 18th century, at Eṣfahān, Iran

Ray Manley—Shostal Assoc / EB Inc

the decoration of illuminated manuscripts, walls, furniture, metalwork, and pottery. These designs usually were composed of either twining or sinuous scrolls of branches and leaves or ornate lines abstracted from such natural forms. Human figures often were integral to Western arabesque designs. Though the word had meant simply "Arabian" in 16th-century France, it was defined in a dictionary of 1611 as "rebesque work, a small and curious flourishing."

The earliest Western models inspiring the work of early Renaissance Italian artists were actually ancient Roman stucchi, plaster models found in Roman tombs. Arabesque stonework was designed by the mid-15th century, and painting in the style executed by Giulio Romano and the pupils of Raphael decorated the open galleries, or loggie, of the Vatican in the following century. Delicate silverwork of northern Italy and, later, Spain also used the motifs, and they began to appear in the decoration of majolica at Urbino, armour at Milan, tapestry at Florence, and illuminated manuscripts at Mantua.

Renaissance arabesques maintained the classical tradition of median symmetry, freedom in detail, and heterogeneity of ornament. The arabesque of this period also allowed the inclusion of a broad range of elements—human beings, beasts, birds, fishes, flowers—in imaginative or fantasy scenes, usually with copious interlacings of vines, ribbons, or the like.

With the coming of the Baroque, the use of arabesque decoration fell into disfavour until the middle of the 18th century, when a new series of Roman arabesques was discovered at Herculaneum. In 1757 the Comte de Caylus published his *Recueil de peintures antiques* ("Collection of Ancient Paintings"), and by 1770 engraved models for arabesques again were being published in Paris. The late reliefs and paintings are among the most beautiful arabesques ever produced, but the formality of Directoire and Empire design after the Revolution gradually ended the fashion.

'Arabi, Ibn al- (Muslim mystic-philosopher): see Ibn al-'Arabi.

Arabia, Arabic JAZIRAT AL-'ARAB ("Island of the Arabs"), peninsular region, together with offshore islands, located in southwestern Asia. It is bounded by the Red Sea (west and southwest), the Gulf of Aden (south), the Arabian Sea (south and southeast), the Gulf of Oman and the Persian (or Arabian) Gulf (northeast), and Iraq, Jordan, and the Gulf of Aqaba (north). Its area is about 1,000,000 square miles (2,590,000 square km).

A brief treatment of Arabia follows. For full treatment, see MACROPAEDIA: Arabia.

Politically, Arabia comprises the territory of seven sovereign countries: the Kingdom of Saudi Arabia (the largest political division); the Republic of Yemen; the Sultanate of Oman; and the Persian Gulf states of the United Arab Emirates, Qatar, Bahrain, and Kuwait. There is also a small, nonsovereign Neutral Zone, shared by Saudi Arabia and Kuwait. The population of the peninsula in 1990 was approximately 32,138,000.

The land. Arabia is a basin-shaped plateau, which forms a peninsula separated from the sea on three sides by mountains. The plateau slopes gently northeastward from the mountains behind the Red Sea coast toward the fourth side, the eastern lowland areas adjoining the Persian Gulf. Geologically, the mountains on the western side of the peninsula behind the Red Sea coast constitute a single province with those across the Red Sea, to which they were once joined and from which they have been separated by the geological action of the East African Rift System in opening the Red Sea some 50,000,000 years ago. This geological activity is still apparent in the incidence of damaging earthquakes. The southern wall of mountains also slopes gently inward toward the centre of the geologically stable Arabian Shield. Broad black lava fields and extinct volcanoes, characteristic of the western Arabian landscape, overlie the shield. The interior of the plateau is marked by a succession of sandy desert regions from an-Nafūd in the northwest to the Rub' Al-Khālī (Empty Quarter) in the south. Sandy coastal lowlands surround the Persian Gulf in the northeast.

None of the mountain regions is particularly high, with the maximum elevation on the peninsula at Ḥāḍur Shu'ayb in Yemen, 12,336 feet (3,760 m) above sea level. The narrow coastal plain that separates the plateau from the sea on three sides contains much of the cultivated land (most of it in Yemen and Saudi Arabia) and most of the trading cities that for 3,000 years have connected the region with the rest of Asia and Africa.

The wall of mountains keeps most of the peninsula very dry (usually less than 4 inches [100 mm] of rainfall annually), except for a few eastern areas under the influence of the Indian Ocean monsoon and far western coastal areas, which benefit from the mountain rain barrier. The most congenial areas for human habitation are those of the Yemens in the south, where rainfall may reach 20 to 40 inches (500 to 1,000 mm) annually. Elsewhere, temperatures are often terribly hot (reaching 129° F [54° C]) in the summer, and, although the climate may be pleasant in spring and fall, it is still usually too dry to permit much cultivation. There are seasonal winds, such as the shamal from the north-northwest and (less frequently) the *kaus* from the southeast. Geological evidence indicates that in the past the peninsula has been much more hospitable to human settlement and habitation, even during comparatively recent times. The wadis, seasonal watercourses, once were year-round streams.

Salt scrub is the only natural vegetation in much of Arabia's desert and highland areas. In the better-watered Yemen and Asir regions, cactuslike euphorbia, eucalyptus, bud-

dlea scrub, aloe, and other types of vegetation grow naturally, but overgrazing by livestock and terracing for agriculture in general have reduced natural vegetation to useless patches. Arabia is largely devoid of trees, except for the date palm, which can be grown almost anywhere and was for centuries a staple of domestic economy. Some other trees, such as acacia, tamarisk, and mimosa, are used as windbreaks to stabilize dunes. Alfalfa (lucerne) is often planted as a fodder crop, and such crops as cotton, wheat, and millet also are cultivated.

Animal life includes mammals such as wolf, hyena, fox, honey badger, and mongoose, widely distributed but small in numbers. Bird life is more extensive, but many are seasonal migrants; included are eagles, hawks, and falcons (long used for sport and hunting); owls; flamingos; and others. The status of nature protection is precarious; many species have been hunted to virtual extinction. Marine life in the surrounding seas is rich and varied, particularly among the reef areas of the Red Sea.

The only important mineral resources in the peninsula are petroleum and natural gas. Arabia has almost half of the world's petroleum reserves. Most of these deposits are on or off the shore of the Persian Gulf, and their exploitation also leads to extraction of associated sulfur. In association with the petroleum there are also large amounts of natural gas. Gypsum and marble are quarried; other mineral resources in the region include copper, phosphate, gold, silver, iron ore, and barite.

The people. The people of Arabia are mostly ethnic Arabs whose geographical distribution generally follows patterns of rainfall and arable soil: the Najd, or central region of settlement on the plateau, has the city of Riyadh as well as many smaller agricultural towns; similarly, the Asir of the well-watered southwestern highlands; the Persian Gulf littoral, more populous than ever because of the oil industry; and the highlands of Yemen, one of the most populous sections of the peninsula. There is also a relatively small indigenous Bedouin community. Saudi Arabia has the largest population of the countries in Arabia, followed by Yemen.

The population of Arabia is estimated to be growing at one of the highest annual rates in the world. The birth rate is relatively high almost everywhere in Arabia, while death rates vary widely. Throughout most of Arabia the population is very young; in many regions almost 45 percent of the population is under 15 years of age. Most of the population are speakers of Arabic, though in many regional dialects. The great majority are Sunnite Muslims; Arabia believes itself heir to the great tradition of Muslim proselytism that carried Islām as far as Spain and China, and today, 2,000,000 pilgrims annually are attracted to Mecca, the great historical centre of Islām.

More than two-thirds of the population is urban in most of Arabia. Oman and Yemen are between about 10 and 25 percent urban, principally because of their tradition of small agricultural towns. Most of the countries have several major cities each. Government planning for regional and urban development generally is predicated on the creation of new urban centres (for better provision of services), rather than on maintaining existing rural populations in an improved environment.

The economy. The economies of the countries of Arabia can be characterized as free-enterprise in nature, though most of the enterprise is strictly controlled by either a royal family or the planning authorities of the countries themselves. The aggregate gross national product (GNP) of the seven countries constituting Arabia originates largely from extracting and refining petroleum. The GNP per capita is very unevenly distributed within Arabia, varying from among the lowest in the world in Yemen to one of the highest GNP

per capita in the world in the United Arab Emirates. Only Yemen has an agriculture sector that exceeds 7 percent of the gross domestic product (GDP). Manufacturing amounts to about 12 percent of the GDP, except in Saudi Arabia and Oman, where it is much less. The service sector typically contributes about half of each country's GDP.

Agricultural land usually amounts to less than 1 percent of land area. Somewhat less than one-third of the total population, however, is still employed in agriculture in Arabia; Yemen and Saudi Arabia have by far the largest agricultural labour forces. The region is not self-sufficient in food production and is very dependent on good weather, although as much as 30 percent of agricultural land is watered or irrigated from subsurface water supplies. Crops range from cereal grains (where the climate permits) to melons and fruits (at the better-watered oases) to aromatic essences and spices, coffee, and the stimulant khat (*qāt*; in the terraced fields of Yemen). Principal livestock includes cattle, asses, and camels (Yemen and Saudi Arabia), as well as sheep and goats (which are omnipresent and probably responsible for much of the degradation of the vegetation of Arabia during historic times). Fisheries are not economically significant, although most coastal towns have a small fishing fleet.

Most national development plans in the region have provided heavy investment in the expansion of the manufacturing sector to prepare for the end of the century, when oil reserves will be exhausted and jobs will be needed for these countries' burgeoning populations to replace income no longer provided by oil.

The principal industry, however, is still the refining of oil. The construction sector is very active, providing the infrastructure, new cities, pipelines, and other facilities that will be required for the self-sustaining economy it is hoped will replace the oil windfalls. The service sector is dominated by financial services and technical services to the oil industry.

The principal labour problems are those associated with the massive adjustment of Arabia's traditional economies to oil income and with the modernization of those like Yemen. Especially in the smaller producing countries, a major problem is the millions of guest workers attracted to the Arabian Peninsula after 1970 both by jobs and by the entrepreneurial opportunities of such great wealth. These workers and their dependents represent a strain on existing services and a potential social and political problem after the boom.

Arabian banking—private, commercial, and development—experienced dynamic growth in the early 1980s, largely owing to the prosperity of the oil industry. Economic and political relations among the countries of Arabia are arranged through such organizations as the Arab League, the Organization of Arab Petroleum Exporting Countries, the Arab Fund for Economic and Social Development, and the Arab Monetary Fund.

Internal surface transportation in the Arabian Peninsula is very poorly developed, except around the Persian Gulf and in the Saudi Arabian heartland, the Asir, and the main coastal commercial routes connecting the peninsula with neighbouring countries. And, except in the Persian Gulf area, roads seldom connect any country with another. A 360-mile (580-kilometre) railroad connects the port of Ad-Dammān with Riyadh. Air travel, particularly since the 1960s, has substituted for the inadequate road system. Gulf Air, Kuwait Airways, and Saudia (over a network of airports, especially in Saudi Arabia) are capable of transporting almost any equipment.

Although the peoples of Arabia have a long seafaring tradition, in the late 20th century only Saudi Arabia, Kuwait, and the United Arab Emirates had sizable fleets of merchant

vessels, primarily oil tankers. Ports and harbours, however, are numerous and, in the Persian Gulf, among the largest and most technologically modern in the world, handling extremely large crude-petroleum carriers of more than 500,000 tons displacement. Except in Kuwait, where oil wells were damaged or destroyed during the Persian Gulf war (1991), a vast network of oil, gas, and petroleum-product pipelines carries these goods from fields and refineries to the Persian Gulf ports from which they are then transported.

In international trade, the export of oil dominates all. Although the enormously increased import levels of the 1970s and early 1980s could be financed without difficulty, in 1982 the world recession, the glut of oil on world markets, and the drop in oil prices generally resulted in a decrease in oil income, foreign exchange and repayment problems, and more emphasis on industrial development outside of the petroleum-producing sector. Principal imports include machinery and equipment, especially construction equipment; transportation equipment, particularly trucks; complete structures such as turnkey plants; textiles and clothing; and food. The major export customers are the industrialized countries of western Europe and North America. The major import suppliers are the United States, Japan, and Germany.

Government and social conditions. The governmental forms of the countries of Arabia range from the loosely republican form of the Republic of Yemen and the partially (until the mid-1970s) constitutional monarchies of the Bahrain and Kuwait to the more unrestricted monarchies of the remaining countries. Constitutional forms are not traditional to the region and are poorly developed.

The governments of the Arabian Peninsula generally have not adopted the political party as a form of public discourse. No country in the peninsula finds it expedient to permit public expression of opposition views.

Throughout most of Arabia, traditional Islamic law, or *Shari'ah*, is the basis of civil and criminal sanctions; the *Shari'ah* is administered by local *qadis*, or judges. Only in Kuwait is a modern legal code in force.

The states of the peninsula tend to be nonaligned or Western in orientation. Those countries that were dependencies or protectorates of the United Kingdom continue to maintain a strong connection with the United Kingdom for military advice, training, and materiel; the United States is also a principal supplier.

Standards of living until the early 1970s were often unsatisfactory because the countries of the region were so poor. The surge of oil wealth begun in the 1970s permitted the creation of so much new social infrastructure that by the early 1980s life expectancy had risen to the 70-year mark in the most-developed of the Arabian countries, like Kuwait, although it remained nearer 50 years for the larger, less-developed parts of Arabia. Infant mortality and nutritional standards followed a similar pattern. Health manpower was difficult to train and recruit; most modern services were available only in the largest cities. The main health problems are those associated with supply and improvement of potable water (though the increasing use in the peninsula of desalinated water is alleviating this), sewage disposal, and vector (insects or animals carrying communicable diseases) control. The major diseases in the rural areas were malaria, trachoma, gastroenteritis, and influenza; in the cities the urban problems of automobile accidents, cardiovascular disease, malignant neoplasms (cancers), and mental illness were of growing significance.

Housing, though susceptible of improvement during the 1970s through the infusion of oil money and the creation by the oil industry of a work force skilled in construction tech-

niques, remained insufficient to supply the rapidly growing population. In many of the older cities, the building of the new has advanced so far that traditional housing types can no longer be seen.

Education is recognized as a development tool by all of the countries of Arabia, but the traditional separation of the sexes has often meant much lower enrollment ratios for women than for men. Literacy is still low (and extremely low in Yemen) in the least-developed regions but is somewhat higher in the larger oil-exporting countries, like Saudi Arabia (almost 60 percent), and reaches more than 70 percent in the small oil-producing countries where large numbers can be reached by literacy programs in the cities. University education usually is pursued outside the region, although higher vocational and teacher-training institutions were established, especially during the 1970s, for maintenance of traditional religious and cultural values within the framework of development.

Social security programs are not as comprehensive as in more developed regions, and although Saudi Arabia, Kuwait, and Bahrain had such programs, by the early 1980s most of the population was not covered.

The desert culture. The great age of the nomadic Arabs immediately preceded Islam; *i.e.*, it spanned the 6th and early 7th centuries AD. Because some of them deliberately had abandoned settled life for freedom in the desert, nomads were deeply convinced of their superiority to sedentary groups. Settled peoples in contact with the desert tended to accept this belief and to adopt many nomadic values, and the nomadic outlook dominated Arabia during this period.

Each desert group was believed to be constituted by descent from a common ancestor. In the early Islamic period kinship was reckoned in the male line. Some tribes in pre-Islamic times followed matrilineal kinship predominantly, practicing forms of polyandry. Islamic preference for patrilineal descent was ensured by religious proscription; a woman was restricted to one husband at a time, though a man might have four legal wives as well as slave concubines.

Not all inhabitants of Arabia were nomads. Scattered over most of the country were oases with subtropical agriculture; a few near the west coast had tropical vegetation.

The oasis about which most is known is Yathrib, since Muhammad's time known as Medina. There and throughout Arabia agriculture seems to have been pioneered by tribes or clans professing Judaism. All were indistinguishable from their Arab neighbours except in religion. Each tribe and clan had small forts or castles to which they could retire when attacked. Otherwise they lived on their lands. There appears to have been no concentration of dwellings anywhere in the oasis until after the coming of Muhammad. In other cases an oasis supported part of an Arab tribe, the remainder being nomadic.

Of the small settlements without oasis agriculture, Mecca became by far the most important. Modern Mecca has a little agriculture but seems to have had none in the 6th century. The original population probably was a family that controlled and served the shrine. Later known as the Ka'bah, the shrine had a sanctuary area around it; the months for pilgrimage to the shrine were designated sacred. In the sacred territory and during sacred periods, blood feuds were in abeyance. Members of hostile tribes met there peacefully to make Mecca a growing trade centre. By AD 600 its merchants held monopolistic control of the trade route from the Yemen to Gaza and Damascus; another route linked Mecca to the head of the Persian Gulf.

Material poverty led nomads to use oratory and poetry as the chief form of artistic expression. Oratory is evanescent, but many fine examples of pre-Islamic poetry survive. The normal form is a *qasida* (ode) of 40 to 100 or more lines, each with the same complex metrical scheme and the same rhyme. The most famous examples are from the collection called *Mu'allaqāt*. Among many others preserved are the *divans*, collected poems of individual writers.

Although the *qasida* is said to have developed in the first half of the 6th century, earlier experimentation is presupposed; even the oldest known show maturity, high quality, and generally a standard order of topics. First came the *nasib* (an elegiac prelude), which set the mood for reflection. The heart of the poem either boasted of the poet's tribe including himself, satirically exposed the shame of a hostile tribe, or was a panegyric on a patron. The writer's art became manifest in his treatment of these fixed subjects, perhaps itself a reflection of attempts to function nobly in the narrow limits of desert life. As the chief art form, poetry had high social importance, exalting the tribe and its adherence to the highest values of desert nomads. In some ways the poet was comparable to the modern journalist, and the satire of an accomplished writer was greatly feared.

History. Although archaeological work in the Arabian Peninsula is still in its infancy, there is evidence that Arabia was the home of Paleolithic hunters. Finds on the Persian Gulf attest Arabian connections with Sumer cultures as early as the 3rd millennium BC.

South Arabia was the location of the peninsula's greatest pre-Islamic kingdoms. The Ma'in, Saba' (the Biblical Sheba), Qatabān, and Ḥaḍramawt kingdoms flourished in the southwestern corner, growing wealthy from the lucrative trade in frankincense and spices. The Sabaens built a dam at Ma'rib and an elaborate irrigation system from it. Their kingdom gave way to that of the Ḥimyarites (c. 100 BC), who ruled South Arabia until AD 525, when they were destroyed by the Christian Abyssinians.

In South Arabia the domestication of the camel (c. 400 BC) and increasing demand by northern civilizations for frankincense and myrrh led to prosperity for the south (Yemen and Oman). By 330 BC a network of roads linked the southern highlands of the peninsula. In the north the Nabataeans controlled the trade route up the Red Sea coast to Egypt and Syria.

Ethnically, the people of Arabia have been related to different groups whose homelands lie in almost all directions outside Arabia proper. Important tribes of the interior of the peninsula were the Thamūd, located in the northern Hejaz near the Red Sea, and the Liḥyānites, who were located in and around Dedan.

Arabic peoples not located in Arabia itself influenced and controlled much of the peninsula in early times. The Nabataeans and the Palmyrenes, on the outskirts of Arabia, extended their authority to the regions of Northern and Central Arabia, through which their trade routes passed. When Palmyra fell in AD 273, power shifted to the Lakhmids of Transjordan, who were the first to adopt Arabic as their official language. In 528 Northern Arabia passed to the Ghassānids, Christians who spoke Syriac.

The Prophet Muḥammad's flight to Medina (622) marks the beginning of the Muslim era. Within a generation, all of Arabia was converted to Islām, but the struggle among Muḥammad's successors led to the establishment of the Umayyad caliphate, headquartered in Damascus. The political centre of Is-

lām never returned to the Arabian Peninsula, and it was characterized thereafter by petty kingdoms, intertribal warfare, and incursions from non-Arab Islāmic powers.

The Ottomans attempted to exert control over all of Arabia in the 16th century, but their penetration was short-lived in South Arabia and nonexistent in parts of the interior and the Persian Gulf. The Persians tried to take Bahrain (17th and 18th centuries) and the Portuguese Oman (16th and 17th centuries), but both were repulsed by native leaders.

As the Sa'ūdi family, under Wahhābi influence, was spreading over Central Arabia, the British were establishing protectorates in the Persian Gulf: Muscat (later Oman) in 1798, the Trucial States (later the United Arab Emirates) and Bahrain in 1820, Aden in 1839, Kuwait in 1899, and finally Saudi Arabia itself in 1915. The territory that later became Yemen (Ṣan'ā') was never under British protection and received recognition of its independence in 1934. The Saudis achieved independence in 1927. As for the rest of the peninsula, Kuwait became independent in 1961, Yemen (Aden) achieved independence in 1967, and Oman became independent in 1970. With the evacuation of the British from the Arabian Peninsula, Bahrain, Qatar, and the United Arab Emirates (composed of Abu Dhabi, Dubai, Ajman, Sharjah, Umm al-Qaiwain, Ras al-Khaimah, and Fujairah) gained independence in 1971. Yemen (Ṣan'ā') and Yemen (Aden) were united in 1990.

Arabia, Roman province created out of the former kingdom of the Nabataeans and the adjacent Syrian cities of Gerasa and Philadelphia (modern Jarash and 'Ammān, Jordan, respectively), after the formal annexation of the Nabataean kingdom by the Roman emperor Trajan in AD 105. The province was

capital and legionary camp, but the old royal capital of Petra remained the religious centre. By constructing a road linking Damascus, via Bostra, Gerasa, Philadelphia, and Petra, to Aelana on the Gulf of Aqaba, the Romans further strengthened the province's communications and secured control over restless Bedouin tribes to the east.

At the end of the 3rd century, the Roman emperor Diocletian divided Arabia into a northern province, enlarged by the Palestinian regions of Auranitis and Trachonitis, with Bozrah as the capital, and a southern province, with Petra as capital. The southern province, united to Palestine by the emperor Constantine I the Great, became known as Palaestina Salutaris (or Tertia) when detached again in AD 357-358. The cities of both provinces enjoyed a marked revival of prosperity in the 5th and 6th centuries and fell into decay only after the Arab conquest in 632-636.

Arabia Felix (Latin: "Happy, or Flourishing, Arabia"), in ancient geography, the comparatively fertile region in southwestern and southern Arabia (in present-day Asir and Yemen), a region that contrasted with Arabia Deserta in barren central and northern Arabia and with Arabia Petraea ("Stony Arabia") in northwestern Arabia, which came under the suzerainty of imperial Rome. The Greeks and Romans chose the name because of the area's pleasant climate and reputed riches in agricultural products and in spices. The emperor Augustus (reigned 27 BC-AD 14) sent an expedition under Gaius Aelius Gallus to Arabia Felix, with disastrous results. Partly because of a native guide's treachery, the troops traveled by a circuitous way through waterless regions, so that they reached southern Arabia weakened by disease, heat, and want of water, unable to accomplish much commercially or politically. But the expedition did bring back a considerable knowledge of the country and its products. *See also Saba'.*

Arabian Basin, submarine basin of the southern Arabian Sea, rising to meet the submerged Carlsberg Ridge to the south, the Maldive Island chain to the southeast, India and Pakistan to the northeast, Iran to the north, and the Arabian Peninsula to the west. It has a maximum depth of 19,275 feet (5,875 m) and is separated by the Carlsberg Ridge from the deeper Somali Basin to the south and west. The sill depth between the Arabian and Somali basins is about 9,800 feet (3,000 m). The floor of the basin is covered by sediment deposited by the Indus River in the form of a great alluvial fan whose thickness diminishes to the south.

Arabian Desert (Egypt): *see* Eastern Desert.

Arabian Desert, great desert region occupying nearly all of the Arabian Peninsula in Southwest Asia, an area of about 900,000 square miles (2,330,000 square km).

A brief treatment of the Arabian Desert follows. For full treatment, *see* MACROPAEDIA: Asia.

The Arabian Desert is bordered by the Syrian Desert to the north; the Persian Gulf, Gulf of Oman, and Arabian Sea to the east; the Arabian Sea and Gulf of Aden to the south; and the Red Sea to the west. A large part of the desert lies within Saudi Arabia; it also extends into Jordan, Iraq, Kuwait, Qatar, the United Arab Emirates, Oman, and Yemen.

Two major regions comprise the desert: the ancient Arabian Platform (or Afro-Arabian Shield) of igneous and metamorphic rocks in the west, and the younger sedimentary rocks that dip gently away from the shield toward the Persian Gulf basin to the east. Mountainous highlands rise in the northwest, southwest, and southeast corners of the desert; steep cliffs and canyons descend from the highlands into adjacent seas to the south and west. To

The Roman province of Arabia, c. AD 200

bounded by the western coast of the Sinai Peninsula, the present Syrian-Lebanese border to a line south of Damascus, and the eastern coast of the Red Sea as far as Egra (Madā'in Ṣāliḥ in the Hejaz). It prospered economically in the 2nd century, and it became a source of customs revenue to the Romans because of the South Arabian caravan and maritime trade in incense and other Far Eastern commodities that passed through the area. Under the Romans, Bostra (Bozrah; now Buṣrā ash-Shām, Syria) in the extreme north became the

the north and east, elevations decrease more gradually to the moderate relief of the interior plateaus and broad plains or steppes. A number of lesser highland ranges have been uncovered by erosion in the interior.

Sand covers at least a third of the Arabian Desert, occurring as dunes or ridges of varying size and complexity or as a thin film on surfaces of low relief. The two largest sand bodies are an-Nafūd in the northwest and the Rub 'al-Khali in the southeast. Between them are two almost parallel arcs of more or less continuous dunes, separated by the Tuwayq Mountains. Twice a year shamal winds blow at velocities averaging 30 miles per hour (50 km per hour) from the north and northwest for 30 to 50 days, transporting huge loads of sand and dust and altering the shapes of sand dunes. Summer heat in the desert is intense, with daytime highs reaching 129° F (54° C). In the interior the heat is dry and tolerable, but coastal regions and some highlands suffer from high summer humidity.

Rainfall averages less than 4 inches (100 mm) a year but can range from 0 to 20 inches (500 mm). Most drainage channels in the desert are either dry or intermittent, the latter flowing only when rains are heavy. Two systems flow perennially in the region—the Tigris-Euphrates river system in the northeast and the Wadi Ḥajr in the southern Hadhramaut (Hadhramāwt) region of Yemen. Plants of the Arabian Desert are structurally adapted to dry or saline conditions.

Humans have inhabited the desert since early Pleistocene times (the Pleistocene lasting from about 1.6 million to 10,000 years ago). The nomadic Bedouin adapted to desert life by migrating seasonally with their herds of camels, Arabian horses, and sheep into the desert during the rainy winter season and moving back toward the cultivated lands in the dry summer months. Date palms are grown in many oases, the dates providing food for humans and livestock, and the palm supplying wood for building. Many fruits, grains, and vegetables, such as rice, alfalfa, henna, citrus, melons, onions, tomatoes, barley, and wheat, are also grown in the oases, and—in the higher regions—peaches, grapes, and prickly pears. The Arabian people, Muslim from the 7th century AD, remained largely unaffected by Western cultural influences until the discovery of petroleum in 1936. Their desert, once crossed only by camel trails, is now laced by networks of roads; about four-fifths of the territory is accessible by motor vehicles.

Arabian Gulf (Indian Ocean): *see* Persian Gulf.

Arabian horse, earliest improved breed of horse, valued for its speed, stamina, beauty, intelligence, and gentleness. The breed's long history has been obscured by legend, but it had been developed in Arabia by the 7th century AD. The Arabian horse has contributed

its qualities to most of the modern breeds of light horses.

The Arabian breed is a compact, relatively small horse with a small head, protruding eyes, wide nostrils, marked withers, and a short back. It usually has only 23 vertebrae, while 24 is the usual number for other breeds. The horse's average height is about 15 hands (60 inches, or 152 cm), and its average weight ranges from 800 to 1,000 pounds (360 to 450 kg). It has strong legs and fine hooves. The coat, tail, and mane are of fine, silky hair. Although many colours are possible in the breed, gray prevails. The most famous stud farm is in the region of Najd, Saudi Arabia, but many fine Arabian horses are now bred elsewhere.

Arabian Sea, northwestern part of the Indian Ocean covering a total area of about 1,491,000 square miles (3,862,000 square km).

A brief treatment of the Arabian Sea follows. For full treatment, *see* MACROPAEDIA: Indian Ocean.

The Arabian Sea is bounded to the east by India, to the north by Pakistan and Iran, and to the west by the Arabian Peninsula and the Horn of Africa. It is located north of an imaginary line connecting Cape Comorin at the southern tip of India to Xaafuun (Hafun) Point, a peninsula on the eastern coast of Somalia. To the north, the Gulf of Oman connects the Arabian Sea with the Persian Gulf via the Strait of Hormuz. To the west, the Gulf of Aden connects it with the Red Sea via the Strait of Bab el-Mandeb. Nations bordering the sea include India, Pakistan, Iran, Oman, Yemen, and Somalia.

Islands in the sea include Socotra (a part of Yemen), off the Horn of Africa; the Kuria Muria Islands, off the coast of Oman; and the Lakshadweep islands (a part of India), off the southwestern coast of India. Among the chief ports are Bombay in India, Karāchi in Pakistan, and Aden in Yemen. The Indus is the principal river draining into the sea.

Most of the Arabian Sea has depths that exceed 9,800 feet (3,000 m), and deep water reaches close to the bordering coastlines except in the northeast, off Pakistan and India. The Carlsberg Ridge, a submarine belt of elevated seafloor characterized by high seismic activity, divides the Arabian Sea into two major basins—the Arabian Basin to the east and the Somali Basin to the west. The mean depth of the sea is 8,970 feet (2,734 m); the maximum depth, 19,038 feet (5,803 m), is located at Wheatley Deep.

High levels of inorganic nutrients, such as phosphate concentrations, which support a rich fish life, occur off the southeastern coast of the Arabian Peninsula. The chief fish include tuna, sardine, billfish, wahoo, shark, lancet fish, and moonfish, but fishing operations have yet to be fully developed. The sea lies within the trade wind latitudes and was part of the principal sea route between Europe and India for centuries.

Arabic alphabet, second most widely used alphabetic writing system in the world (the Latin alphabet is the most widespread). Originally developed for writing the Arabic language and carried across much of the Eastern Hemisphere by the spread of Islām, the Arabic script has been adapted to such diverse languages as Persian, Turkish, Spanish, and Swahili. Although it probably developed in the 4th century AD as a direct descendant of the Nabataean alphabet, its origins and early history are vague. Some scholars believe that the earliest extant example of Arabic script is

a royal funerary inscription of the Nabataeans dating from AD 328. Others believe that this epigraph shows characteristics of Arabic but is essentially Aramaic and that the earliest extant example of Arabic is a trilingual inscription in Greek, Syriac, and Arabic dating from AD 512.

The Arabic alphabet has 28 letters, all representing consonants, and is written from right to left. Twenty-two of the letters are those of the Semitic alphabet from which it descended, modified only in letter form, and the remaining six letters represent sounds not used in the languages written in the earlier alphabet. The shape of each letter depends on its position in a word—initial, medial, and final. There is a fourth form of the letter when it is written alone. The letters *alif*, *waw*, and *ya* (standing for glottal stop, *w*, and *y*, respectively) are used to represent the long vowels *a*, *u*, and *i*. A set of diacritical marks developed in the 8th century AD are sometimes used to represent short vowels and certain grammatical endings otherwise left unmarked.

Two major types of Arabic script exist. Kūfic, a thick, bold monumental style, was developed in Kūfah, a city in Mesopotamia, toward the end of the 7th century AD. It was used chiefly for inscriptions in stone and metal but was also employed sometimes to write manuscripts of the Qur'ān. A very handsome monumental script, it has passed out of use, except in cases in which more cursive scripts cannot be used. *Naskhi*, a cursive script well adapted to writing on papyrus or paper, is the direct ancestor of modern Arabic writing. It originated in Mecca and Medina at an early date and exists in many complex and decorative variant forms.

Arabic language, Southern-Central Semitic language spoken in a large area including North Africa, most of the Arabian Peninsula, and other parts of the Middle East. (*See* Afro-Asiatic languages.)

Arabic is the language of the Qur'ān (or Koran, the sacred book of Islām) and is the religious language of all Muslims. Literary Arabic, usually called Classical Arabic, is essentially the form of the language found in the Qur'ān, with some modifications necessary for its use in modern times; it is uniform throughout the Arab world. Colloquial Arabic includes numerous spoken dialects, some of which are mutually unintelligible. The chief dialect groups are those of Arabia, Iraq, Syria, Egypt, and North Africa. With the exception of the dialect of Algeria, all Arabic dialects have been strongly influenced by the literary language.

The sound system of Arabic is very different from that of English and the other languages of Europe. It includes a number of distinctive guttural sounds (pharyngeal and uvular fricatives) and a series of velarized consonants (pronounced with accompanying constriction of the pharynx and raising of the back of the tongue). There are three short and three long vowels (*a*, *i*, *u*; *ā*, *ī*, *ū*). Arabic words always start with a single consonant followed by a vowel, and long vowels are rarely followed by more than a single consonant; clusters containing more than two consonants do not occur in the language.

Arabic shows the fullest development of typical Semitic word structure. An Arabic word is composed of two parts: (1) the root, which generally consists of three consonants and provides the basic lexical meaning of the word, and (2) the pattern, which consists of vowels and gives grammatical meaning to the word. Thus, the root *ktb* combined with the pattern *-i-ā-* gives *kitāb* ("book"), whereas the same root combined with the pattern *-ā-i-* gives *kātib* ("one who writes," or "clerk"). The language

Arabian horse
Sally Anne Thompson

also makes use of prefixes and suffixes, which act as subject markers, pronouns, prepositions, and the definite article.

Verbs in Arabic are regular in conjugation. There are two tenses: the perfect, formed by the addition of suffixes, which is often used to express past time; and the imperfect, formed by the addition of prefixes and sometimes containing suffixes indicating number and gender, which is often used for expressing present or future time. In addition to the two tenses there are imperative forms, an active participle, a passive participle, and a verbal noun. Verbs are inflected for three persons, three numbers (singular, dual, plural), and two genders. In Classical Arabic there is no dual form and no gender differentiation in the first person, and the modern dialects have lost all dual forms. The classical language also has forms for the passive voice.

There are three cases (nominative, genitive, and accusative) in the declensional system of Classical Arabic nouns; nouns are no longer declined in the modern dialects. Pronouns occur both as suffixes and as independent words.

With the spread of literacy and the increase in higher education in the Arab world, the influence of Classical Arabic on the colloquial dialects has become greater.

Arabic language, South: see South Arabic language.

Arabic literary renaissance, Arabic *AN-NAḤDAH AL-ADABIYAH*, 19th-century movement to a modern Arabic literature, inspired by contacts with the West and a renewed interest in the great classical literature.

After the Napoleonic invasion of Egypt (1798) and the subsequent establishment of an autonomous and Western-minded ruling dynasty there, many Syrian and Lebanese writers sought out the freer environment of Egypt, making it the centre of the renaissance. Under the impact of the dismemberment of the Ottoman Empire after World War I and the coming of independence after World War II, the revival spread to other Arab countries.

The novel and drama, literary forms new to Arabic literature, were developed largely under the influence of the European works that became available in the 19th century in Arabic translation. Other forms owed much to Western models but had roots in classical Arabic literature, such as the short story, new verse forms, and the essay.

That the renaissance succeeded in altering the direction of Arabic literature is probably attributable to two factors. The emergence of an Arabic press made writing a realistic livelihood and forced writers to abandon the traditional, ornate style of past centuries in favour of a simpler and more direct style that would appeal to a wider reading public. The spread and modernization of education further served to provide a body of readers receptive to new styles and ideas.

Arabic literature, writings in the Arabic language, composed or written by non-Arabs as well as Arabs. In the golden age of Arabic literature following the advent of Islām in 622, Arabic writers included Persians, Iranians, Indians, Spanish Muslims, Egyptians, Syrians, and many others of mixed descent, all of whom made their distinctive contributions to Arabic literature.

A brief treatment of Arabic literature follows. For full treatment, see *MACROPAEDIA: Islamic Arts: Islāmīc literatures.*

Arabic literature is divided into two main periods. The classical, beginning with the proverbs and poetry of the nomadic northern Arabs of the desert, was preserved by oral transmission from the early 6th century or before and first recorded in the 7th and 8th

centuries; though the Arabic leadership in the Islāmīc world began to decline in the 11th century, classical Arabic literature continued into the 16th century.

Within the classical period, there is a major division between the pre-Islāmīc literature of the 6th and early 7th centuries and the literature that followed the rise and spread of Islām. The literature of the Islāmīc period is not a religious literature, except in the later part of the period, when Šūfism (Islāmīc mysticism) influenced Arabic poetry. This influence is also seen in Persian and Turkish literature, which, in the Islāmīc period, are interwoven with that in Arabic (as is Indian literature). The conquest of most of the Arabic-speaking world in the 16th and 17th centuries essentially eradicated Arabic literature in that time.

The modern period, beginning with the 19th-century literary renaissance in Syria, Egypt, Lebanon, and Iraq, drew some of its impetus from contact with the West and some from renewed interest in the great classical literature. It started on the one hand in Egypt, where France's short occupation (1798–1801) was followed by the autonomous ruling dynasty established by the viceroy and pasha of Egypt, Muḥammad 'Alī; on the other, in Syria and Lebanon, where Christian communities—especially the Maronite Church—had been in contact with Europe since the 16th century. The freer environment of Egypt led many Syrian and Lebanese writers to emigrate there, and Egypt thus became the centre of the renaissance. Later it spread to other Arab countries, particularly under the impact of the dismemberment of the Ottoman Empire after World War I, and the coming of independence after World War II. These developments were strengthened by the emergence of an Arabic press and by the spread and modernization of education.

Aracaju, port city and capital, Sergipe *estado* ("state"), northeastern Brazil, lying on the Continguiaba River at the base of a ridge of sand hills 6 miles (10 km) from the coast. The city, which was founded in 1855 as a new state capital, is laid out in an unusual grid pattern. It is a regional commercial and industrial centre, processing leather, bananas, cassava, *feijão* (beans), mangoes, cashews, salt, cotton, and sugar. Chemicals are also produced in Aracaju, and limestone is quarried in the vicinity. Anchorage at the port is good, but a dangerous bar at the river's mouth prevents the entrance of vessels drawing more than 12 feet (4 m). Small-scale offshore petroleum drilling was begun in the late 1970s. Aracaju is linked by air, coastal shipping, and paved roads to Salvador, Maceió, and Recife. The Federal University of Sergipe was founded there in 1967. Pop. (2000 prelim.) 460,898.

aracari, any of certain toucan species. See toucan.

Araçatuba, city, western São Paulo *estado* ("state"), Brazil, near the Tietê River, which is dammed for power and irrigation. The city was founded in 1908 and was given town rank in 1917. In 1921 it was separated administratively from Penápolis (to the southeast) and was designated the seat of a municipality. It serves an agricultural area (cotton, coffee, rice, corn [maize], and *feijão* [beans]). Araçatuba processes cotton and foodstuffs and produces tannin, ceramics, shoes, and other items. Goods are shipped by highway to São Paulo and to other cities in the state. Araçatuba also has an airfield. Pop. (2000 prelim.) 164,440.

Arachne (Greek: "Spider"), in Greek mythology, the daughter of Idmon of Colophon in Lydia, a dyer in purple.

Arachne was a weaver who acquired such skill in her art that she ventured to challenge Athena. The goddess wove a tapestry depicting the gods in majesty, while that of Arachne

showed their amorous adventures. Enraged at the perfection of her rival's work, Athena tore it to pieces, and in despair Arachne hanged herself. But the goddess out of pity loosened the rope, which became a cobweb; Arachne herself was changed into a spider, whence the name of the zoological class to which spiders belong, Arachnida.

arachnid, any member of the class Arachnida, phylum Arthropoda, which is composed of primarily carnivorous invertebrates, including the spiders, scorpions, mites, and ticks.

A brief treatment of arachnids follows. For full treatment, see *MACROPAEDIA: Arachnids.*

Arachnid bodies are segmented, with well-developed heads and hard external skeletons. They range in size from the tiny mite 0.1 mm (0.004 inch) long to the 18-centimetre (7-inch) black scorpion of Africa. The body is divided into two parts: the cephalothorax (joint head and thorax), with six pairs of appendages, and the abdomen, or opisthosoma. The first two pairs of appendages, the chelicerae and the pedipalps, are used to hold or grasp prey. The remaining pairs are walking legs. Arachnids have no antennae but rely on tactile hair, simple eyes, and slit sense organs for sensory information.

Courtship among arachnids is necessary, with the male giving off a chemical or visual key or exhibiting a characteristic behaviour. The male arachnid usually deposits the sperm on the ground as a spermatophore or constructs a special web called a sperm web and then transfers it into the female. Most arachnids lay eggs, but some species (*e.g.*, scorpions) bear live young. The degree of maternal care varies among arachnids but is an important part of survival for newborn scorpions, which are carried on the female's back.

As arachnids grow they molt, or shed their cuticles, several times before reaching maturity. All arachnids, except harvestmen, are unable to digest their food internally; they inject digestive fluids into their prey and suck the liquefied remains into their mouths.

Many arachnid forms are distributed worldwide, inhabiting nearly every region from deserts to rain forests. Most arachnid groups are free-living, but many species of mites and ticks are parasitic. The latter also are carriers of serious human and animal diseases. Certain venomous spiders and scorpions pose a danger to humans, but most are harmless and prey on insect pests.

arachnodactyly: see Marfan's syndrome.

'Arad, town, southern Israel, in the northeast Negev, named for the biblical Arad, the ruins of which are visible at Tel 'Arad, about 5½ miles (9 km) east-northeast. The book of Numbers (21:1–3) tells how the Canaanite king of 'Arad fought the Israelites during the exodus from Egypt, but his cities were "utterly destroyed" by Israel's armies. The city's name appears on the Temple of Amon, al-Karnak, Egypt, in the triumphal inscription of Pharaoh Sheshonk I (biblical Shishak), first ruler of the 22nd dynasty (reigned c. 945–924 BC).

Modern housing with memorial to town's dead in the Arab-Israeli War of 1967, 'Arad, Israel

Ehud Locker—Shostal/EB Inc

The first modern attempt to settle the site was made in 1921 by veterans of the Zion Mule Corps, a Jewish unit of the British army in World War I. It failed because of the lack of freshwater. 'Arad is now supplied with water by a branch of the Yarqon-Negev pipeline. The present settlement was founded in 1961 and is a residential community for the employees of the Dead Sea Works at nearby Sedom. The hinterland of 'Arad has valuable mineral resources—in addition to the minerals of the Dead Sea, there are phosphate deposits at Zefa', 10 miles (16 km) south, and natural-gas fields at Rosh Zohar, 3 miles (5 km) southeast. Chemical processing and textile manufacturing are the town's principal industries. Pop. (2002 est.) 24,500.

Arad, județ (county), western Romania, bounded on the west by Hungary. The Mureș and Crișul Alb rivers flow westward through the county, while the Western Carpathians, including the Zărand and Codru-Moma ranges, lie in the eastern portion. Settlements are found in the lowlands and intermontane valleys. Cereal growing, livestock raising, and vineyard and fruit cultivation are the main agricultural activities.

Arad city, the county capital, passed through Roman, Tatar, Turkish, and Hungarian hands. Lipova has a 14th-century building that was converted into a mosque during the Turkish occupation (1552–1699). A 15th-century castle and a nature reserve are located at Savârșin. A highway and a railway line that parallel the Mureș River were based on a former Roman road. Area 2,954 square miles (7,652 square km). Pop. (2002) 461,730.

Arad, city, capital of Arad județ (county), western Romania. It is located in the lower Mureș River valley close to the Hungarian border, 30 miles (50 km) north-northeast of Timișoara. The city has a large Magyar (Hungarian) population.

The site became a Roman outpost south of the river at Aradu Nou ("New Arad"). The first documented mention of Arad dates from 1156. Arad was in Turkish hands, with brief interruptions, from 1552 until 1699, when it came under the control of Austria. During the Hungarian rebellion of 1848–49, it was captured by the Hungarians in 1849 and was made their headquarters. After the rebellion was put down, with the assistance of Russia, 13 Hungarian generals, "the martyrs of Arad," were executed there on Oct. 6, 1849. Arad became part of Romania after World War I.

Arad is a commercial and industrial centre. Its manufactures include machine tools, railway cars, and textiles. The city has a theatre, an orchestra, and a cultural centre with a library and museum. Pop. (2002) 172,824.

'Arafāt, Yāsir, byname of MUḤAMMAD 'ABD AR-RA'ŪF AL-QUḌWAH AL-ḤUSAYNĪ (b. Aug. 24?, 1929, Cairo?, Egypt—d. Nov. 11, 2004, Paris, France), president (1996–2004) of the Palestinian Authority, chairman (1969–2004) of the Palestine Liberation Organization (PLO), and leader of Fatah, the largest of the constituent PLO groups. In 1993 he led the PLO in a peace agreement with the Israeli government. 'Arafāt and Yitzhak Rabin and Shimon Peres of Israel were jointly awarded the Nobel Prize for Peace in 1994.

'Arafāt was one of seven children of a well-to-do merchant whose wife was related to the anti-Zionist grand mufti of Jerusalem, Amīn al-Ḥusaynī (d. 1974). 'Arafāt attended the University of Cairo, graduating as a civil engineer. He joined the Muslim Brotherhood and the Union of Palestinian Students, of which he was president (1952–56), and was commissioned into the Egyptian army. In 1956 he served in the Suez campaign.

After Suez, 'Arafāt went to Kuwait, where he worked as an engineer and set up his own contracting firm. While there, he cofounded

Fatah, which was to become the leading military component of the PLO. After being named chairman of the PLO in 1969, he became commander in chief of the Palestinian Revolutionary Forces in 1971 and, two years later, head of the PLO's political department. In November 1974 'Arafāt became the first representative of a nongovernmental organization—the PLO—to address a plenary session of the UN General Assembly.

In 1982 'Arafāt was criticized by various Syrian-supported factions within the PLO and by Syria. The criticisms escalated after the Israeli invasion of Lebanon forced 'Arafāt to abandon his Beirut headquarters in August 1982 and set up a new base in Tunisia; he shifted to Baghdad, Iraq, in 1987. 'Arafāt was subsequently able to reaffirm his leadership as the split in the PLO's ranks healed. In 1989 'Arafāt was elected by the Central Council of the Palestine National Council (the governing body of the PLO) to be the president of a hypothetical Palestinian state. In 1993 'Arafāt, as head of the PLO, formally recognized Israel's right to exist and helped negotiate the Israel-PLO accord. 'Arafāt began directing Palestinian self-rule in 1994, and in 1996 he was elected president of the Palestinian Authority (*q.v.*).

In mid-1996 Israeli-Palestinian relations became acrimonious. Growing distrust between 'Arafāt and Israeli Prime Minister Benjamin Netanyahu stalled peace efforts until 1998, when U.S. President Bill Clinton intervened, arranging a summit meeting with the two leaders at Wye Mills, Md. In the resulting agreement, the two sides pledged to complete the peace process. In 2000 'Arafāt rejected an offer that would have created an independent Palestinian state, because it did not grant the Palestinians full control over East Jerusalem or adequately guarantee, in his view, the right of Palestinian refugees to return. In 2001 Israeli Prime Minister Ariel Sharon blamed 'Arafāt for instigating suicide attacks in Israel and confined 'Arafāt to his headquarters in Rām Allāh. In October 2004 'Arafāt fell ill and was transported for medical treatment to Paris, where he died the following month.

Arafura Sea, shallow sea of the western Pacific Ocean, occupying 250,000 square miles (650,000 square km) between the north coast of Australia and the Gulf of Carpentaria and the south coast of New Guinea. It merges with the Timor Sea on the west and the Banda and Ceram seas on the northwest. The Torres Strait connects it with the Coral Sea on the east. Most of the Arafura Sea is underlain by the Arafura Shelf, part of the more extensive Sahul Shelf. It is generally shallow, with depths of 165 to 260 feet (50 to 80 m), deepening at its western edge, on which coral growths rise from 2,000-foot (610-m) depths. The Arafura Shelf appears to have been a low-relief land surface that had an arid climate before it became inundated by the postglacial rise of the sea. The Aru Islands in the north, formed by localized uplift, border the Aru Trough, a curving trench that reaches a maximum depth of 12,000 feet (3,660 m). The trough is part of a chain of depressions that underlie the Ceram, Arafura, and Timor seas, extending west as the Java Trench in the Indian Ocean.

Aragats, Mount, Russian GORA ARAGATS, also spelled GORA ARAGAC, mountain in Armenia, northwest of Yerevan and north of the Ararat Plain. The highest point in both Armenia and the Lesser Caucasus range (13,418 feet [4,090 m]), Aragats is a circular, shieldlike mountain composed of both lavas and tufas. A volcanic cone of recent geologic age lies atop far older rocks. The crater of the volcano has become the steep-walled basin, or cirque, of a glacier, and there are several other minor glaciers. Near the jagged summit are high mountain meadows and rockfalls. On the slopes can be found steppe vegetation and xerophytes (dry and arid climate vegetation).

Arago, François, in full DOMINIQUE-FRANÇOIS-JEAN ARAGO (b. Feb. 26, 1786, Estagel, Roussillon, France—d. Oct. 2, 1853, Paris), French physicist who discovered the principle of the production of magnetism by rotation of a nonmagnetic conductor. He also devised an experiment that proved the wave theory of light and engaged with others in research that led to the discovery of the laws of light polarization.

Arago was educated in Perpignan and at the École Polytechnique, Paris, where, at the age of 23, he succeeded Gaspard Monge in the chair of analytic geometry. Subsequently he was director of the Paris Observatory and permanent secretary of the Academy of Sciences. He was also active as a republican in French politics. As minister of war and marine in the provisional government formed after the Revolution of 1848, he introduced many reforms.

In 1820, elaborating on the work of H.C. Ørsted of Denmark, Arago showed that the passage of an electric current through a cylindrical spiral of copper wire caused it to attract iron filings as if it were a magnet and that the filings fell off when the current ceased. In 1824 he demonstrated that a rotating copper disk produced rotation in a magnetic needle suspended above it. Michael Faraday later proved these to be induction phenomena.

Arago supported A.-J. Fresnel's wave theory of light against the emission theory favoured by P.-S. Laplace, J.-B. Biot, and S.-D. Poisson. According to the wave theory, light should be retarded as it passes from a rarer to a denser medium; according to the emission theory, it should be accelerated. Arago's test for comparing the velocity of light in air and in water or glass was described in 1838, but the experiment required such elaborate preparation that Arago was not ready to perform it until 1850, when his sight failed. Before his death, however, the retardation of light in denser media was demonstrated by A.-H.-L. Fizeau and Léon Foucault, who used his method with improvements in detail.

In astronomy, Arago is best known for his part in the dispute between U.-J.-J. Le Verrier, who was his protégé, and the English astronomer John C. Adams over priority in discovering the planet Neptune and over the naming of the planet. Arago had suggested in 1845 that Le Verrier investigate anomalies in the motion of Uranus. When the investigation resulted in Le Verrier's discovery of Neptune, Arago proposed that the newly found planet be named for Le Verrier.

Aragon, Spanish ARAGÓN, *comunidad autónoma* ("autonomous community") and historical region of northeastern Spain. It encompasses the *provincias* of Huesca, Zaragoza (Saragossa), and Teruel and was established by the statute of autonomy of Aug. 10, 1982.

History. The modern autonomous community of Aragon is roughly coextensive with the historical kingdom of Aragon. This principality had its origins in 1035, when Sancho III the Great of Navarre left to his third son, Ramiro I, the small Pyrenean county of Aragon and established it as an independent kingdom. To this mountain domain Ramiro added the counties of Sobrarbe and Ribagorza to the east. By 1104 Aragon's kings had doubled its size by conquests southward toward the Ebro River. Zaragoza, the capital of the Almoravid kingdom, fell to Alfonso I of Aragon (1104–34) in 1118. The reconquest of present-day Aragon from the Muslims had been completed by the late 12th century. In 1179 Aragon reached an agreement with the neighbouring Christian kingdom of Castile under which those parts of Spain remaining in Muslim hands were divided into two zones—one for each kingdom to reconquer.

In 1137 the ruler of Catalonia, Ramon Berenguer IV, count of Barcelona, married the heiress of the kingdom of Aragon. The union of Aragon and Catalonia principally benefited the Catalans, who dominated the state until 1412. The union enabled the Catalans to devote themselves to commerce and maritime expansion, knowing that the financial and military responsibility of defending them from Castile would fall largely on the inhabitants of the Aragonese hinterland.

The Aragonese kings meanwhile continued to expand their domains, reconquering the rich kingdom of Valencia from the Muslims in 1238. Having thus completed the occupation of the Muslim territories allotted to it by the treaty of 1179, Aragon began expanding into the Mediterranean area, a move made possible by the sea power of the Catalans. In 1282, after the Sicilian Vespers, Peter III of Aragon (1276–85) was received by the Sicilians as their king, and thenceforth Sicily was ruled either directly by the kings of Aragon or by their relatives. Sardinia was incorporated into the Aragonese empire in 1320, and in 1442 Alfonso V of Aragon (1416–58) successfully concluded his long struggle to conquer the kingdom of Naples. Navarre, which had been ruled by Aragon from 1076 to 1134, came under its rule again in 1425.

By the 15th century the nobles of Aragon proper had come to favour union with Castile to counterbalance the power of the mercantile Catalans. Their chance came in 1412 when, after the extinction of the house of Barcelona in 1410, they procured the election of a Castilian prince, Ferdinand of Antequera, to the vacant Aragonese throne over strong Catalan opposition. One of Ferdinand's successors, John II of Aragon (1458–79), countered residual Catalan resistance by arranging for his heir, Ferdinand, to marry Isabella, the heiress of Henry IV of Castile. In 1479, upon John II's death, the kingdoms of Aragon and Castile were united to form the nucleus of modern Spain. The Aragonese lands, however, retained autonomous parliamentary and administrative institutions until the early 18th century, when their constitutional privileges were abrogated by Philip V. The old kingdom of Aragon survived as an administrative unit until 1833, when it was divided into the three existing provinces.

Physical and human geography. Modern Aragon is bounded by France (north) and by the autonomous communities of Catalonia (east), Valencia (southeast), Castile-La Mancha (southwest), and Castile-León, La Rioja, and Navarre (west). Mountains dominate the relief north and south of the east-west-trending Ebro River basin, which bisects Aragon into northern and southern portions. Administratively, Zaragoza province occupies the Ebro basin and is flanked by Huesca province to the north and Teruel province to the south. The Pyrenees rise to more than 9,840 feet (3,000 m) and extend southward from France into Huesca. Their foothills, the pre-Pyrenees, decline in height southward to the Ebro basin. The Ebro River drains most of Aragon with the exception of its southernmost portion, which is linked to the Tagus River basin and the Mediterranean. The Iberian Cordillera (Sierra de Gúdar) occupies almost all of Teruel province as well as the southwestern corner of Zaragoza.

Annual precipitation is low throughout most of Aragon, averaging about 14 inches (350 mm). It is also highly variable, ranging from 8 to 24 inches, with the result that dry farming is extremely precarious. A Mediterranean climate prevails except in the Pyrenees, and precipitation is concentrated in the autumn and spring.

The population tends to be concentrated in

the irrigated zones of the Ebro River basin and is much sparser in the adjoining mountains. In Huesca and Teruel the population has declined since the early 20th century, when grape phylloxera destroyed numerous vineyards there. Meanwhile the population of the province and city of Zaragoza has grown at the expense of Huesca and Teruel. Fully one-half of Aragon's population lives in Zaragoza city.

Most of the land under cultivation is dry-farmed, producing crops of wheat, olives, and grapes. The land under irrigation, however, is far more productive and accounts for the better part of Aragon's agricultural output. The principal crops of the irrigated zones are fodder, cotton, sugar beets, and fruit.

The government has sponsored various projects to expand the land under irrigation. By 1904 the Canal of Aragon and Catalonia had brought wide stretches of land in the province of Huesca under irrigation, while the Plan Bardenas and the Plan Monegros, both initiated after 1945, brought many additional acres under irrigation. The Bardenas Canal channels the Arba and Aragon rivers and centres around the town of Ejea de los Caballeros, while the Monegros Canal draws on rivers south of Huesca town. Large-scale irrigated farming of cereals (barley, wheat, and corn [maize]) and fruits is found in Zaragoza province and livestock farming, especially pig rearing, is important in Huesca.

Aragon's industrial sector is heavily concentrated in greater Zaragoza. The introduction of sugar beets in the late 19th century hastened the industrialization of the city; seven sugar refineries were established there between 1900 and 1905. Metalworking is now Zaragoza's leading industry, however, with electric appliances, machinery, railway equipment, and automobiles being the leading manufactures. Textiles, footwear, and clothing are also produced.

Aragon's primary source of energy is hydroelectricity, generated by the damming of the Ebro River and its northern affluents in Huesca. Teruel province is a traditional lignite and iron-ore mining region. The railroad reached Zaragoza in 1864, and highways now connect that city with Spain's major industrial centres. Area 18,425 square miles (47,720 square km). Pop. (1994 est.) 1,183,576.

Aragon, Louis, original name LOUIS ANDRIEU (b. Oct. 3, 1897, Paris, France—d. Dec. 24, 1982, Paris), French poet, novelist, and essayist who was a political activist and spokesman for communism.

Through the Surrealist poet André Breton, Aragon was introduced to avant-garde movements such as Dadaism; and together with Philippe Soupault, he and Breton founded the Surrealist review *Littérature* (1919). Aragon's first poems, *Feu de joie* (1920; "Bonfire") and *Le Mouvement perpétuel* (1925; "Perpetual Motion"), were followed by a novel, *Le Paysan de Paris* (1926; *The Nightwalker*). In 1927 his search for an ideology led him to the French Communist Party, with which he was identified thereafter, as he came to exercise a continuing authority over its literary and artistic expression. In 1928 he met Elsa Triolet (the Russian-born sister-in-law of the poet Vladimir Mayakovsky), who became his wife and his inspiration (she died in 1970).

In 1930 Aragon visited the Soviet Union, and in 1933 his political commitment to communism resulted in a break with the Surrealists. The four volumes of his long novel series, *Le Monde réel* (1933–44; "The Real World"), describe in historical perspective the class struggle of the proletariat toward social revolution. Aragon continued to employ Socialist Realism in another long novel, *Les Communistes* (6 vol., 1949–51), a bleak chronicle of the party from 1939 to 1940. His next three novels—*La Semaine sainte* (1958; *Holy Week*), *La Mise*

à mort (1965; "The Moment of Truth"), and *Blanche ou l'oubli* (1967; "Blanche, or Forgetfulness")—became a veiled autobiography, laced with pleas for the Communist Party. They reflected the newer novelistic techniques of the day.

The poems of *Le Crève-Coeur* (1941; "Heart-break") and *La Diane française* (1945) express Aragon's ardent patriotism, and those of *Les Yeux d'Elsa* (1942; "Elsa's Eyes") and *Le fou d'Elsa* (1963; "Elsa's Madman") contain deep sentiments of love for his wife. From 1953 to 1972 Aragon was editor of the communist cultural weekly *Les Lettres Françaises*. He was made a member of the French Legion of Honour in 1981.

aragonite, widespread mineral, the stable form of calcium carbonate (CaCO₃) at high pressures. It may be distinguished from calcite, the commoner form of calcium carbonate, by its greater hardness and specific gravity. Aragonite is always found in deposits formed at low temperatures near the surface of the Earth, as in caves as stalactites, in the oxidized zone of ore minerals (with lead substituting for calcium), in serpentine and other basic rocks, in sediments, and in iron-ore deposits. Aragonite is the mineral normally found in pearls. It is polymorphous (same chemical formula but different crystal structure) with calcite and vaterite, and, with geologic time, probably inverts to calcite even under normal conditions. For detailed physical properties, see carbonate mineral (table).

Aragonite is an important element in the shells and tests of many marine invertebrates. These animals can secrete the mineral from waters that would ordinarily yield only calcite; they do so by physiological mechanisms that are not fully understood.

Aragua, estado ("state"), northern Venezuela. It is bounded north by the Caribbean Sea, east by the Distrito Federal and Miranda state, south by Guárico state, and west by Carabobo state. Aragua consists largely of two Andean ranges separated by an intermontane basin, in which lies Lake Valencia. Henri Pittier National Park (413 square miles), with its exceptionally rich and varied flora, occupies the entire northern portion of Aragua. The park stretches from the Caribbean seacoast south across the northeasternmost of the two Andean ranges. The state's climate is tropical, and, though there is considerable rain inland, the coast is dry. The Aragua River valley produces a variety of agricultural products. Although sugarcane has ranked first for many years, potatoes have also attained high commercial value. Other important crops include cacao, coffee, cotton, corn (maize), rice,

Sugarcane plantation, Aragua valley, Venezuela
Georges de Steinheil

and tobacco. Aragua still ranks high in cattle, but herds have diminished as rangelands are converted to farmlands. The state's industrial development has been notable, particularly in and around the state capital, Maracay (*q.v.*). The state has a good system of hard-surface roads. Area 2,708 square miles (7,014 square km). Pop. (1995 est.) 1,335,303.

Araguaia River, Portuguese RIO ARAGUAIA, river, central Brazil. It rises on the Brazilian Highlands near Alto Araguaia town in Mato Grosso state and flows north-northeast for 1,632 miles (2,627 km) to its junction with the Tocantins River, at São João do Araguaia. Its upper course forms the boundary between Mato Grosso state (west) and Goiás and southern Tocantins states (east). In midcourse the river divides into two channels on either side of Bananal Island, which is about 200 miles (320 km) long and the site of the National Park of Araguaia. The major, western arm is interrupted by many falls and rapids; the smaller, eastern channel can be navigated by small boats. The lower course of the Araguaia forms the boundary between Pará state (west) and northern Tocantins state (east). Although the Araguaia drains a vast area of interior Brazil, it offers poor transportation, for it is frequently interrupted by falls. Hydroelectric projects were built on the river during the late 20th century to provide power. The area around the Araguaia's upper course has unexploited minerals, including uranium, copper, cobalt, zinc, and diamonds.

Araguari, city, western Minas Gerais state, Brazil, on the Jordão River, a tributary of the Paranaíba River, at 3,051 feet (930 m) above sea level. Formerly called Freguesia do Brejo Alegre, the settlement was made the seat of a municipality in 1882 and was elevated to city rank in 1888. Araguari's main source of income is from the large herds of cattle raised in the hinterlands, where rice, corn (maize), *feijão* (beans), and cassava are also cultivated. The city has an airport and is accessible by railroad and highway from other urban centres in Minas Gerais and Goiás states. Pop. (2000 prelim.) 92,389.

arahant (Buddhism): *see* arhat.

Arai Hakuseki (b. March 24, 1657, Edo [now Tokyo]—d. June 29, 1725, Edo). Japanese statesman and scholar who was a chief adviser to the Tokugawa shoguns in the early years of the 18th century.

Born into an impoverished samurai, or warrior, family, Arai educated himself under conditions of extreme hardship. He found employment in 1682 under Hotta Masatoshi (1634–84), a top government official. When Hotta died two years later, Arai became tutor to Tokugawa Ienobu (reigned 1709–12), the heir apparent to the shogun, or hereditary military dictator of Japan. Ienobu became shogun in 1709, and Arai became the leading architect of government policy.

The Tokugawa government had grown lax, and bureaucratic rigidity had come to hamper efficiency. Arai attempted to make the laws of the country more practical; he reformed the currency and instituted a rigid system of budgeting and accounting. To stop the drain of precious metals from the country, he further tightened governmental control over foreign trade. Arai attempted to institute a policy by which it would be clear to foreign powers that Japan's emperor was merely symbolic and real sovereignty resided with the shogun.

Although Ienobu died in 1712, Arai remained in the government throughout the reign of his successor, Tokugawa Ietsugu. But when the strong-minded Tokugawa Yoshimune came to power in 1716, Arai was forced to retire. He then devoted the rest of his life to writing.

Arai's works total more than 160 books. He wrote pioneering studies in Japanese geography, philosophy, and legal institutions and is considered one of the greatest historians of Japan. Among his best-known works are *Dokushi yoron* ("A Reading of Political History"), a study of Japanese history from the 9th to the 16th century; *Koshi tsū* ("The Understanding of Ancient History"), a critical study of the earliest documentary sources; and his autobiography, *Oritaku shiba no ki*.

Arakan, coastal geographic region in southern Myanmar (Burma). It comprises a long, narrow strip of land along the eastern coast of the Bay of Bengal and stretches from the Naf estuary on the border of the Chittagong Hills area (in Bangladesh) in the north to the Gwa River in the south. The Arakan region is about 400 miles (640 km) long from north to south and is about 90 miles (145 km) wide at its broadest. The Arakan Yoma, a range that forms the eastern boundary of the region, to some extent isolates it from the rest of southern Myanmar. The coast has several sizable offshore islands, including Cheduba and Ramree. The region's principal rivers are the Naf estuary and the Mayu, Kaladan, and Lemro rivers.

Only one-tenth of Arakan's generally hilly land is cultivated. Rice is the dominant crop in the delta areas, where most of the population is concentrated. Other crops include fruits, chilies, *dhani* (thatch), and tobacco. The natural hillside vegetation of evergreen forest has been destroyed over wide areas by shifting cultivation (slashing and burning to clear land for cultivation) and has been replaced by a useless tangle of bamboo.

The main towns are coastal and include Sittwe (Akyab), Sandoway, Kyaukpyu, and Taungup. Long accessible only by sea, the Arakan region is now linked by air and road with the rest of the country. An all-weather road running through a pass in the Arakan Yoma connects Taungup with Pyè on the Irrawaddy River.

Arakan Mountain Range, Burmese ARAKAN YOMA, mountain arc in western Myanmar (Burma), between the Arakan coast and the Irrawaddy River valley. The arc extends northward for about 600 miles (950 km) from Cape Negrais (Myanmar) to Manipur (India) and includes the Nāga, Chin, Lushai, and Pātakai hills. The mountain range itself is about 250 miles (400 km) long. Its highest point is Mount Victoria (10,150 feet [3,094 m]). Dividing the Arakan coast from the rest of Myanmar, the range historically has been a barrier between Myanmar and the Indian subcontinent. It functions as a climatic barrier, cutting off the southwestern monsoon rains from central Myanmar. Arakan Mountain Range is crossed by the An route to Ngape and Minbu and by an all-weather road from Taungup to Pyè on the Irrawaddy.

Arakanese, member of a Myanmar (Burmese) ethnic group centered in the Arakan coastal region of southern Myanmar (Burma). The Arakanese are Buddhists of Myanmar stock and possess a dialect and customs of their own. Separated from the parent group in central Myanmar by the mountains of the Arakan Yoma, they trace their history to 2666 BC, have had a lineal succession of as many as 227 princes, and claim that their empire once extended across Myanmar into China and Bengal. Although history does not corroborate these claims, the Arakanese's most sacred image of the Buddha, the huge Mahamuni statue (now in Mandalay), is alleged to predate the Pagan kingdom (1044–1287) by a millennium. An independent Arakanese kingdom was probably established as early as the 4th century AD. The Mongols, Pegus, and Portuguese invaded Arakan at different times. Myanmar forces conquered the Arakanese kingdom, carried off the Mahamuni statue to Mandalay, and made Arakan a part of the Myanmar kingdom in 1785. As a province, Arakan was ceded to the British in 1826 by the Treaty of Yandabo. Arakan became independent from British rule in 1948 together with the rest of Myanmar. *See also* Mrohaung, Arakanese Kingdom of.

Arakcheyev, Aleksey Andreyevich, Graf (Count) (b. Oct. 4 [Sept. 23, Old Style], 1769, Novgorod province, Russia—d. May 3 [April

21], 1834, Gruzino, Novgorod province), military officer and statesman whose domination of the internal affairs of Russia during the last decade of Alexander I's reign (1801–25) caused that period to be known as Arakcheyevshchina.

The son of a minor landowner, Arakcheyev studied at the Artillery and Engineering Corps for Noble Cadets from 1783 to 1787 and was commissioned an artillery officer in the Russian army in the latter year. He became a close associate and adviser to the tsarevich

Arakcheyev, detail of an engraving by N.I. Utkin after a portrait by G. Wagner, 1818

Novosti Press Agency

Paul, who, when he became emperor in 1796, gave Arakcheyev the task of reorganizing the entire army. When his harsh disciplinary measures alienated the officers' corps, however, he was dismissed (1798) and was recalled to active duty only after Alexander I ascended the throne. Made an inspector general of the artillery in 1803, Arakcheyev reorganized that branch of the army; he then became minister of war (1808), and in 1809, during the Russo-Swedish War of 1808–09, he personally compelled the reluctant Russian forces to cross the frozen Gulf of Finland and make the attack on the Aland Islands that ultimately resulted in Sweden's cession of Finland to Russia (September 1809).

Arakcheyev generally opposed the liberal administrative and constitutional reforms considered by Alexander, and, when Alexander created the advisory Council of State (1810), Arakcheyev resigned as minister of war. He later accepted a post as head of the council's military department; and, as one of Alexander's most trusted military advisers, he handled all of the emperor's military correspondence and dispatches during the invasion by Napoleonic France in 1812. Afterward, when Alexander became almost exclusively involved in foreign affairs, Arakcheyev was made responsible for supervising the Council of Ministers' management of domestic matters (1815).

For the next decade Arakcheyev dominated the administration of Russia's internal affairs, carrying out his bureaucratic functions with brutal and ruthless efficiency. Despite his basic conservatism, he took part in the emancipation of serfs in Russia's Baltic provinces (1816–19) and also developed a plan for gradually emancipating all of Russia's serfs (1818). In addition, he supervised the creation of a system of military-agricultural colonies, which between 1816 and 1821 housed nearly one-third of Russia's standing army. After Nicholas I succeeded Alexander (1825), Arakcheyev resigned all of his offices (April 1826) and went into retirement.

Araki Sadao (b. May 26, 1877, Tokyo, Japan—d. Nov. 2, 1966, Totsukawa), Japanese general, statesman, and a leader of the Kōdōha (Imperial Way) faction, an ultranationalistic group of the 1930s. He strongly advocated the importance of character building through

rigid mental and physical discipline, whereas the dominant Tōseiha (Control) faction emphasized the importance of modernization along with self-discipline.

Araki, a graduate of the Army War College, served in the Russo-Japanese War in 1904 and with Japanese forces in Siberia in 1918. He was promoted to lieutenant general in 1927. He was the choice of zealous young officers to head a new cabinet to be created when they executed a planned coup d'état against the government (October 1931); the coup, however, was discovered and foiled. Meanwhile, the Japanese army invaded Manchuria in September 1931, without authorization from Tokyo, and on Feb. 26, 1936, a group of young militant officers attempted a coup and assassinated Prime Minister Saitō Makoto and several cabinet members. Though Araki, who had been appointed minister of war in the Inukai Tsuyoshi cabinet, and other high officers were not connected with the group, Araki was relieved from active duty and placed on the reserve list.

In 1938 the prime minister, Konoe Fumimaro, appointed Araki minister of education in an effort to balance the growing domination by the Tōseiha. Araki vigorously promoted ultranationalism and militarism with profound effects. He remained active in the government throughout World War II. After the war, the International Military Tribunal convicted him of first-class war crimes and sentenced him to life imprisonment. He was released in June 1955 owing to ill health and was subsequently paroled.

Araks River (Asia Minor): see Aras River.

Aral Sea, Russian ARALSKOYE MORE, also spelled ARALSKOJE MORE, large saltwater lake straddling the boundary between Kazakhstan to the north and Uzbekistan to the south. The shallow Aral Sea was formerly the world's fourth largest body of inland water. It nestles in the climatically inhospitable heart of Central Asia, to the east of the Caspian Sea. The Aral Sea is of great interest and increasing concern to scientists because of the remarkable shrinkage of its area and volume in the second half of the 20th century. This change is due primarily to the diversion (for purposes of irrigation) of the riverine waters of the Syr Darya and Amu Darya (rivers), which discharge into the Aral Sea and are its main sources of inflowing water.

The Aral Sea area is characterized by a desert-continental climate of wide-ranging air temperatures, cold winters, hot summers, and sparse rainfall. The sea's average water temper-

ature for July is 73–77° (23–25° C), and ice forms in November and December, when the temperature averages 30.8° F (–0.7° C). The rate of precipitation—an annual average of 4 inches (100 mm) in all—is only a tiny fraction of the lake's traditional rate of evaporation. The most significant factors affecting the water balance of the Aral Sea are river flow (accounting for approximately 80 percent of inflow) and evaporation, which formerly took out each year about the same amount of water that the rivers brought in. Climate may quite considerably influence the long-term variation in the sea's water level. Over the centuries, variations have exceeded 20 feet (6 m), while annual and seasonal variations of between 10 feet (3 m) and less than a foot have been recorded.

In 1960 the surface of the Aral Sea lay 175 feet (53 m) above sea level and covered an area of 26,300 square miles (68,000 square km). The Aral Sea's greatest extent from north to south was almost 270 miles (435 km), while that from east to west was just over 180 miles (290 km). Although the average depth was a shallow 53 feet (16 m) or so, it descended to a maximum of 226 feet (69 m) off the western shore. The Aral Sea derives its name from the Kyrgyz Aral-denghiz, "Sea of Islands"—an apt designation, as there were more than 1,000 islands of a size of 2.5 acres (1 hectare) or more strewn across its waters.

The sea's northern shore—high in some places, low in others—was indented by several large bays. The low-lying and irregular eastern shores were interrupted in the north by the huge delta of the Syr Darya and in the south were bordered by a wide tract of shallow water. The equally vast Amu Darya delta lay on the lake's southern shore, and along the lake's western periphery extended the almost unbroken eastern edge of the 820-foot- (250-metre-) high Ustyurt Plateau.

The Aral Sea depression was formed toward the beginning of the Pleistocene Epoch (about 1,600,000 years ago), when the Earth's crust subsided and the hollow was filled with water—some of which came from the Syr Darya. In the late Pleistocene Epoch (from about 140,000 until about 10,000 years ago) the depression was inundated for the first time by the Amu Darya, which had temporarily changed its course from the Caspian to the Aral Sea. From the Pleistocene Epoch, the rivers' combined flow maintained a high water level.

From about 1960 the Aral Sea's water level was systematically and drastically reduced because of the diversion of water from the Amu Darya and Syr Darya rivers for purposes of agricultural irrigation. As the Soviet government converted large acreages of pastures or untilled lands in Uzbekistan, Kazakhstan, Turkmenistan, and elsewhere into irrigated farmlands by using the waters of the Amu Darya and Syr Darya, the amount of water from these rivers that reached the Aral Sea dropped accordingly. By the 1980s, during the summer months, the two great rivers virtually dried up before they reached the lake. The Aral Sea began to quickly shrink because of the evaporation of its now-unreplenished waters.

By the late 1980s, the lake had lost more than half the volume of its water and had only slightly more than half its former depth. The salt and mineral content of the lake rose drastically because of this, making the water unfit for drinking purposes and killing off the once-abundant supplies of sturgeon, carp, barbel, roach, and other fishes in the lake. The fishing industry along the Aral Sea was thus virtually destroyed. The ports of Aralsk in the northeast and Muynak in the south were now many miles from the lake's shore. A partial depopulation of the areas along the lake's former shoreline ensued. The drying up of the lake also made the local climate noticeably

harsher, with more extreme winter and summer temperatures.

By 1989 the Aral Sea had receded to form two separate parts, the "Greater Sea" in the south and the "Lesser Sea" in the north, each of which had a salinity almost triple that of the sea in the 1950s. By 1992 the total area of the two parts of the Aral Sea had been reduced to approximately 13,000 square miles (33,800 square km), and the mean surface level had dropped by about 50 feet (15 m). However, plans were made to use less water-intensive agricultural practices in the regions south and east of the lake, thus freeing more of the waters of the Amu Darya and the Syr Darya to flow into the lake and to stabilize its water level.

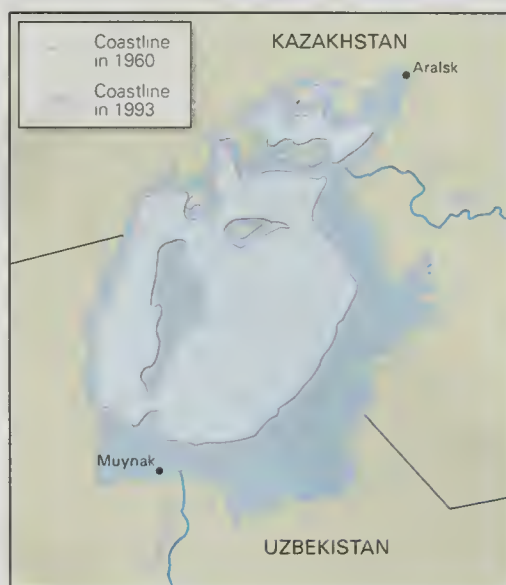

Arales, order of monocotyledonous flowering plants comprising the families Araceae and Lemnaceae. The order includes herbs, climbing shrubs, marsh plants, and floating aquatic forms, most of which live in the tropics.

The Arales may share common evolutionary ancestors with the palm order (Arecales) and the Panama hat palm order (Cyclanthales) from the immediate ancestors of the lily order (Liliales). Arales is rich in popular ornamentals and foliage plants, all in the arum, or aroid, family (Araceae). The duckweed family (Lemnaceae) is remarkable for containing the smallest known flowering plants.

The species may be terrestrial, aquatic, or epiphytic. Some are herbaceous and stemless, with few arrow-shaped leaves arising from a rootstock. Others are climbers, clinging by aerial roots to tree trunks and other upright supports and unfurling large, sometimes dissected, leaves alternately along the stem, with each leaf bearing a temporary, almost colourless sheath at the base of the leaf stalk (petiole). The inflorescence, adapted to insect pollination, is formed of a single spike, or spadix, on which few-to-many minute-to-small flowers are arranged, the entire structure being enveloped by a sometimes colourful floral leaf, or spathe. The spadix often emits a fetid odour that attracts flies, which are trapped for a time and then escape to pollinate other plants. The fruit may be a brightly coloured berry (sometimes many, clustered on the spadix); rarely it is dry and leathery, rupturing to release seed. The sap often contains calcium oxalate crystals, which upon ingestion can numb the tongue and throat.

The Araceae has about 115 genera and 2,000 species, native primarily to the tropics and subtropics. The few temperate zone species are widely distributed, especially in wet habitats. The family is known for several wildings and many greenhouse and foliage ornamentals. The largest genera in the family Araceae are *Anthurium* (600 species); *Philodendron* (275 species); *Arisaema* (150 species), which is believed to be pollinated by snails; *Homalomena* (140 species); *Rhaphidophora* (100 species); *Amorphophallus* (100 species), some species of which produce inflorescences up to 1 m (about 40 inches) tall; *Pothos* (75 species); and *Alocasia* (70 species).

The genera *Philodendron* and *Monstera* are grown for their vinerlike habit and large, green leaves. The elephant's ear (*Colocasia esculenta*) is a variable species that includes the dasheen, taró, and eddo of the tropics; these plants are grown for their large edible corms, or bulblike underground stems. The florist's calla lily is *Zantedeschia aethiopica*, and the genus *Calla* includes the water arum (*C. palustris*); both are grown ornamentally. Species of dumb cane (*Dieffenbachia*) are popular indoor foliage plants that can cause inflammation and swelling of the throat if a piece of stem is chewed. Jack-in-the-pulpit (*Arisaema triphyllum*) is a well-known woodland plant. The golden club (*Orontium aquaticum*) is occasionally cultivated in ponds or greenhouse pools for its bright yellow spadices. Water

(Top left) *Dieffenbachia amoena*; (top right) Jack-in-the-pulpit (*Arisaema triphyllum*); (centre left) skunk cabbage (*Symplocarpus foetidus*); (centre right top) *Anthurium*; (centre right bottom) water lettuce (*Pistia stratiotes*); (bottom left) *Caladium*; (bottom right) duckweed (*Lemna minor*)

(Top left) John H. Gerard (top right) Dr. G. J. Chafaris (centre left) Grant Heilman (centre right top) Joan F. Falk (centre right bottom) Phil Clark (bottom left) Derek Fell (bottom right) Dr. Wm. M. Harlow—Photo Researchers

lettuce, or water cabbage (*Pistia stratiotes*), is an edible and attractive floating ornamental. *Amorphophallus* includes several curiosities grown for their large and ill-smelling inflorescences. Sweet flag rhizome, or calamus root (*Acorus calamus*), contains a spicy, aromatic oil often used in medicines and flavourings. Eastern skunk cabbage (*Symplocarpus*

foetidus) is a well-known marsh plant with a fetid odour. The lords-and-ladies, or cuckoo-pint (*Arum maculatum*), is one of the few arums found as far north as Europe. Several species of *Spathiphyllum* are grown as indoor potted plants. Another beautiful foliage plant is *Caladium*, available in many horticultural varieties with large, colourful leaves.

The Lemnaceae, with 6 genera and 30 species of minute floating aquatic forms, is widespread in the temperate and tropic zones. The family is remarkable for the smallest known flowering plants, the duckweeds (*Lemna* species) and watermeals (*Wolffia* species). Certain of these green, leaflike, flattened species, with or without rootlets and only a few millimetres across, are used in aquariums and pools as ornamentals or as food for waterfowl and fish.

Flowers, rarely produced, bear only the essential organs, no sepals or petals: the male flower has one or two stamens and the female a single pistil. The plants reproduce primarily by basal division.

Araliaceae, the ginseng family of flowering plants, in the order Apiales, comprising approximately 700 species centred in Southeast Asia and tropical America. Most members are shrubs or trees, though there are a number of climbers and a few herbs. The family has large, usually alternate, compound leaves, five-parted flowers arranged in compound umbels

(flat-topped clusters), and a berry or (rarely) a drupe (a one-seeded fruit). Several members of the family are economically important. Ivies (*Hedera* species) are grown as ornamental plants and houseplants. The rice-paper plant (*Tetrapanax papyrifera*) is the source of rice paper, and the wood of several species, especially that of *Dendropanax arboreum* and several members of the genus *Didymopanax*, provides timber.

Wild sarsaparilla (*Aralia nudicaulis*) has an aromatic root that is used as a substitute for sarsaparilla. Ginseng root, from *Panax ginseng*, has long been used by the Chinese in the treatment of various diseases; its American relative, *Panax quinquefolium*, is used in the United States as a stimulant. *Hari-giri*, or castor aralia (*Acanthopanax ricinifolius*), is used in Japan in building and in furniture making.

Aram, Eugene (b. c. September 1704, Rams-gill, Yorkshire, Eng.—d. Aug. 6, 1759, York, Yorkshire), noted English scholar and murderer, whose notoriety was romanticized in a ballad by Thomas Hood and in the novel *Eugene Aram* (1832), by Bulwer-Lytton.

In 1745, when Aram was schoolmaster at Knaresborough, a man named Daniel Clark, his intimate friend, after obtaining a considerable quantity of goods from tradesmen, disappeared. Suspicions of being concerned in this swindling transaction fell upon Aram. His garden was searched, and some of the goods were found there. However, because there was insufficient evidence to convict him of any crime, he was discharged. For several years he traveled through parts of England, acting as usher in a number of schools, and settled finally at Lynn, in Norfolk. During his travels he had amassed considerable material for a projected comparative lexicon of the English, Latin, Greek, Hebrew, and Celtic languages. He was undoubtedly an original philologist, who recognized what was then not yet admit-

ted by scholars, that the Celtic language was related to the other languages of Europe and that Latin was not derived from Greek. But he was not destined to live in history as the pioneer of a new philology.

In February 1758 a skeleton was dug up at Knaresborough, and some suspicion arose that it might be Clark's. Aram's wife had often hinted that her husband and a man named Houseman knew the secret of Clark's disappearance. Houseman was at once arrested and confronted with the bones that had been found. After denials, he confessed that he had been present at the murder of Clark by Aram and another man, Terry, of whom nothing further was heard. He also gave information as to the place where Clark's body had been buried. A skeleton was dug up, and Aram was immediately arrested and sent to York for trial. He was found guilty and condemned to be executed. While in his cell he confessed his guilt and asserted that he had discovered an intimacy between Clark and his own wife.

Aramaean, one of a confederacy of tribes that spoke a North Semitic language (Aramaic) and, between the 11th and 8th century BC, occupied Aram, a large region in northern Syria. In the same period some of these tribes seized large tracts of Mesopotamia.

In the Old Testament the Aramaeans are represented as being closely akin to the Hebrews and living in northern Syria around Harran from about the 16th century BC. The Aramaeans are also mentioned often in Assyrian records as freebooters. The first mention of the Aramaeans occurs in inscriptions of the Assyrian king Tiglath-pileser I (1115–1077). By the end of the 11th century BC, the Aramaeans had formed the state of Bit-Adini on both sides of the Euphrates River below Carchemish and held areas in Anatolia and northern Syria and in the Anti-Lebanon area, including Damascus. About 1030 BC a coalition of the southern Aramaeans, led by Hadadezer, king of Zobah, in league with the Ammonites, Edomites, and the Aramaeans of Mesopotamia, attacked Israel but was defeated by King David.

To the east, however, the Aramaean tribes spread into Babylonia, where an Aramaean usurper was crowned king of Babylon under the name of Adad-apal-iddin. By the 9th century the whole area from Babylon to the Mediterranean coast was in the hands of the Aramaean tribes known collectively as Kaldû (or Kashdu)—the biblical Chaldeans. Assyria, nearly encircled, took the offensive, and in 853 the Assyrian king Shalmaneser III fought a battle at Karkar against the armies of Hamath, Aram, Phoenicia, and Israel. This battle was indecisive, but in 838 Shalmaneser was able to annex the area held by the tribes on the middle Euphrates.

Between Israel and Damascus, intermittent wars were continued until Tiglath-pileser III of Assyria captured Arpad, the centre of Aramaean resistance in northern Syria, in 740 BC. He overthrew Samaria in 734 and Damascus in 732. Finally, the destruction of Hamath by Sargon II of Assyria in 720 marked the end of the Aramaean kingdoms of the west.

Aramaeans along the lower Tigris River maintained their independence longer. In 626 a Chaldean general, Nabopolassar, proclaimed himself king of Babylon and joined with the Medes and Scythians to overthrow Assyria. In the New Babylonian, or Chaldean, empire, Chaldeans, Aramaeans, and Babylonians became largely indistinguishable.

Few specifically Aramaic objects have been uncovered by archaeologists. The Aramaean princes in Syria apparently patronized a provincial form of Syrian art under strong Hittite or Mitannian influence.

In religion, though their pantheon included Canaanite, Babylonian, and Assyrian gods, the Aramaeans had deities of their own. Their chief god was Hadad, or Ramman (Old Testament Rimmon), equated with the Hurrian storm god, Teshub. Their chief goddess was Atargatis (Astar'ate), a fusion of two deities corresponding to the Phoenician Astarte and Anath.

Aramaic alphabet, major writing system in the Middle East in the latter half of the 1st millennium BC. Derived from the North Semitic script, the Aramaic alphabet was developed in the 10th and 9th centuries BC and came into prominence after the conquest of the Aramaean states by Assyria in the 9th and 8th centuries BC.

The Aramaic language and script were used as a lingua franca over all of the Middle East, and documents and inscriptions in the Aramaic alphabet have been found in Greece, India, northern Arabia, and Egypt. The oldest inscription in Aramaic script yet discovered dates from approximately 850 BC.

The Aramaic alphabet consists of 22 letters, all indicating consonants, and it is written from right to left. It is ancestral to Square Hebrew and the modern Hebrew alphabet, the Nabataean and modern Arabic scripts, the Palmyrene alphabet, and the Syriac, as well as hundreds of other writing systems used at some time in Asia east of Syria. Aramaic also has been influential in the development of such alphabets as the Georgian, Armenian, and Glagolitic.

Aramaic language, Semitic language of the Northern Central, or Northwestern, group that was originally spoken by the ancient Middle Eastern people known as Aramaeans. It was most closely related to Hebrew, Syriac, and Phoenician and was written in a script derived from the Phoenician alphabet.

Aramaic is thought to have first appeared among the Aramaeans about the late 11th century BC. By the 8th century BC it had become accepted by the Assyrians as a second language. The mass deportations of people by the Assyrians and the use of Aramaic as a lingua franca by Babylonian merchants served to spread the language, so that in the 7th and 6th centuries BC it gradually supplanted Akkadian as the lingua franca of the Middle East. It subsequently became the official language of the Achaemenian Persian dynasty (559–330 BC), though after the conquests of Alexander the Great, Greek displaced it as the official language throughout the former Persian empire.

Aramaic dialects survived into Roman times, however, particularly in Palestine and Syria. Aramaic had replaced Hebrew as the language of the Jews as early as the 6th century BC. Certain portions of the Old Testament—*i.e.*, the books of Daniel and Ezra—are written in Aramaic, as are the Babylonian and Jerusalem Talmuds. Among the Jews, Aramaic was used by the common people, while Hebrew remained the language of religion and government and of the upper class. Jesus and the Apostles are believed to have spoken Aramaic, and Aramaic-language translations (Targums) of the Old Testament circulated. Aramaic continued in wide use until about AD 650, when it was supplanted by Arabic.

In the early centuries AD, Aramaic divided into East and West varieties. West Aramaic dialects include Nabataean (formerly spoken in parts of Arabia), Palmyrene (spoken in Palmyra, which was northeast of Damascus), Palestinian-Christian, and Judeo-Aramaic. West Aramaic is still spoken in a small number of villages in Lebanon.

East Aramaic includes Syriac, Mandaean, Eastern Neo-Assyrian, and the Aramaic of the Babylonian Talmud. One of the most important of these is Syriac, which was the language of an extensive literature between the 3rd and the 7th century. Mandaean was the dialect of

a Gnostic sect centred in lower Mesopotamia. East Aramaic is still spoken by a few small groups of Jacobite and Nestorian Christians in the Middle East. *See also* Syriac language.

aramina (plant): *see* urena.

Aran Islands, Irish ARAINN, three limestone islands—Inishmore, Inishmaan, and Inishkeer—comprising 18 square miles (47 square km) and lying across the mouth of Galway Bay on the west coast of Ireland. They are

The beach on Inishmaan, Aran Islands, Ireland
Peter Carmichael—Aspect Picture Library

administratively part of County Galway. The islands, whose sheer cliffs face the Atlantic Ocean, are generally bleak. Steamers call at the town of Kilonan on Inishmore, the largest island; the other two islands are accessible only by curragh, a primitive type of boat. The people, who speak Irish, farm and fish under very difficult conditions. The Aran Islands are made up of horizontal sheets of Carboniferous limestone and do not have naturally occurring topsoil. The inhabitants raise crops of oats and potatoes on soil that they have made using seaweed, sand, and manure. Cattle raising is the other major economic activity, and some subsistence fishing is carried on.

Aspects of the islanders' life formed the basis of the play *Riders to the Sea* (1904) and the book of impressions *The Aran Islands* (1907) by John Millington Synge. *Man of Aran*, a documentary film (1934) by Robert Flaherty, also depicted the island life. The islands contain impressive prehistoric and early Christian hill forts and other remains. Author Liam O'Flaherty was a native of Gortnagapul, Inishmore. Pop. (1991) 1,322.

Aranda, also spelled ARUNTA, Aboriginal tribe that originally occupied a region of 25,000 square miles (65,000 square km) in central Australia, along the upper Finke River and its tributaries. The Aranda were divided into five subtribes, which were marked by differences in dialect. In common with other Aborigines, the Aranda were greatly reduced in number during the first 70 years of contact with whites, but by the late 20th century they showed signs of holding their own and even of increasing in number. In 1982 the Aranda people at Hermannsburg in the Northern Territory were given freehold title to their land.

Aranda, Pedro Pablo Abarca de Bolea, conde de (count of) (b. Dec. 18, 1718, Siétamo, Spain—d. Jan. 9, 1798, Épila), Spanish general and minister, one of the most prominent reformers in the government of King Charles III (1759–88).

Aranda came from the Aragonese nobility and entered the army, in which he became di-

rector of the artillery, introduced the Prussian system of drill in the Seven Years' War, and commanded in the short campaign against Portugal (1762). In 1764 he became captain general of Valencia.

In 1766, after riots in Madrid, Charles III dismissed his Italian minister Leopoldo de Gregorio Squillace and called Aranda to be president of the Council of Castile. He convinced Charles that the riots had been instigated by the Jesuits and prepared the decree for their expulsion from Spain and Spanish America in April 1767.

Aranda held strong regalist views, but his authoritarian character caused him difficulty. He was dismissed in 1773 and made ambassador to France, where he remained until 1787 and absorbed "French ideas," becoming an admirer of Voltaire. His friends worked for his return against his rival, the Count de Floridablanca, but Charles III died and Charles IV made no change. When Floridablanca attempted to silence news of the French Revolution and failed to intervene to save Louis XVI, Charles IV was persuaded to dismiss him and recall Aranda, who relaxed the censorship and tried without success to placate the French. In November 1792 he was dismissed and returned to his command. After the French Revolutionists executed their king, Aranda opposed Manuel de Godoy's policy of war with France and was ejected from the royal council and exiled to Jaén. In 1795 Charles allowed him to retire to his estate in Aragon, where he died.

Araneida (arachnid order): *see* spider.

Arango, Doroteo: *see* Villa, Pancho.

Aranha, José Pereira da Graça: *see* Graça Aranha, José Pereira da.

Aranjuez, ancient (Latin) *ARA JOVIS*, town, Madrid province, central Spain, on the southern bank of the Tagus River near its confluence with the Jarama. The town, which has existed since Roman times, was the headquarters of the Knights of Santiago (1387–1409) and became the seat of a royal summer residence and hunting lodge in the 17th century. It was rebuilt in about 1750 by Ferdinand VI. The royal palace (completed in 1778 after being damaged several times by fire) has a large collection of treasures, and the Casita del Labrador, built by Charles IV, who abdicated at Aranjuez in 1808, recalls the Trianons (châteaux) at Versailles, Fr. Aranjuez is on the main railway from Madrid city (29 miles [47 km] north) and serves a rich agricultural district in which asparagus and strawberries are especially important and horses are bred. Industries include the manufacture of chemicals, metal products, and textiles, and the preservation of fruits. Pop. (1998 est.) 38,680.

Aransas National Wildlife Refuge, wildlife refuge in southern Texas, U.S., located about 140 miles (225 km) southwest of Houston on a broad peninsula between San Antonio Bay and Saint Charles Bay, overlooking Matagorda Island and the Gulf of Mexico. Occupying 54,829 acres (22,189 hectares), it consists mostly of upland but does have extensive ponds, lakes, salt marshes, and open parks. It is the principal wintering ground for the rare whooping crane (*q.v.*) and also attracts great numbers of other waterfowl and other birds, varying with the seasons—especially geese, ducks, pelicans, herons, egrets, gulls, sandhill cranes, and various shorebirds. Deer, javelinas, raccoons, turkeys, and other animals are also abundant. Portions of the refuge are open to visitors for purposes of observation. The refuge was established by presidential executive order on Dec. 31, 1937.

Arany, János (b. March 2, 1817, Nagyszalonta, Hung.—d. Oct. 22, 1882, Budapest), the greatest Hungarian epic poet.

Born of an impeccable farming family, he

went to school in Debrecen but abandoned his studies to join for a short time a group of strolling players. Arany made his real advent on the literary scene in 1847 with his popular epic *Toldi*, which was received with enthusiasm by a public craving for a national literature of quality in a language all could grasp. Sándor Petőfi wrote a poem in its praise, and this was the beginning of a lifelong friendship.

In 1848 Arany took part in the Hungarian revolution and for a short period edited a government newspaper for peasants. With the crushing of the revolution he took up teaching. In 1858 he was elected a member of the Hungarian Academy. He moved then from Nagyköros to Pest, where he edited a literary periodical, the *Szépirodalmi Figyelő* (later the *Koszorú*), and was elected first secretary and in 1870 secretary-general of the academy.

Arany's main epic work is the trilogy *Toldi* (1847), *Toldi szerelme* (1848–79; "Toldi's Love"), and *Toldi estéje* (1854; "Toldi's Evening"). Its hero, a youth of great physical strength, is taken from a verse chronicle written by Péter Ilosvai Selymes in the 16th century. Set in the 14th century, the first part of the trilogy relates the adventures of Toldi in

Arany, engraved frontispiece to *Toldi*, 1858

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd

reaching the royal court; the second part tells of his tragic love; and the third, of his conflicts with the king and his death. Though only a fragment, another epic poem, *Bolond Istók* (1850; "Stephen the Fool"), a strange mixture of humour and bitterness, is valuable for Arany's rare moments of self-revelation. Arany started work on a Hun trilogy, connected with Hungarian prehistory, but finished only the first part of it, *Buda halála* (1864; *The Death of King Buda*).

The poems of his two great lyrical periods are fraught with melancholy. The earlier poems, written in the 1850s, are overshadowed by the loss of Petőfi and by Arany's despair for the Hungarian nation and for himself. The *Őszikék*, his beautiful swan songs, written just before his death, poignantly reflect Arany's sense of unfulfillment and solitude.

The best edition of Arany's collected works is by Géza Voinovich, 6 vol. (1951–52).

Āraṇyakas (Sanskrit: "Books of the Forest"), a later development of the *Brāhmaṇas*, or expositions of the Vedas, which were composed in India in about 700 bc. The *Āraṇyakas* are distinguished from the *Brāhmaṇas* in that they may contain information on secret rites to be carried out only by certain persons, and more philosophic speculation. Thus they were intended to be studied only by the initiated, by which might have been meant either hermits who had withdrawn into the forest and no longer took part in ritual sacrifices or pupils who were given instruction by their teachers in the seclusion of the forest, away from the village. The *Āraṇyakas* are given over to secret explanations of the allegorical meaning of the ritual and to discussion of the internal, meditative meaning of the sacrifice, as contrasted to its actual, outward performance. The philo-

sophic portions, more speculative in content, are sometimes called Upanishads.

Arányi, Jelly d' (b. May 30, 1895, Budapest, Hung.—d. March 30, 1966, Florence, Italy), violinist known for her performances of contemporary music. Béla Bartók's two sonatas for violin and piano were written for her; Maurice Ravel's *Tzigane for Violin and Orchestra* and Ralph Vaughan Williams' *Violin Concerto* were dedicated to her.

The grandniece of the celebrated violinist Joseph Joachim, she made her debut in Vienna in 1909. She settled in London in 1913. Her playing was considered fiery and temperamental, and she was esteemed as a performer of Romantic music. Arányi frequently gave joint recitals with pianist Dame Myra Hess. She was also known for performances, with her sister Adila Fachiri (1888–1962), of Bach's double concertos.

Arao, city, Kumamoto *ken* (prefecture), Kyushu, Japan, facing Ariake Bay. It was a poor village until the opening of the Miike coal mine and the arrival of a major railway in the early 20th century. A military munitions factory was established in 1940. After World War II, however, the mine and the factory closed. Arao is now a residential suburb of Ōmuta to the north. Pop. (1995) 57,389.

Arapaho, North American Plains Indian people of Algonquian linguistic stock who lived along the Platte and Arkansas rivers during the 19th century. Their early tradition suggests that they once had permanent villages in the eastern woodlands, where they engaged in agriculture. After a gradual westward movement, they split into northern and southern groups after 1830, the southern group settling in the region of the Arkansas River. Remnants of two or three other divisions have also been recognized.

Like other Plains tribes, the Arapaho were nomadic, living in tepees and depending on the buffalo for existence. They traded with the Mandan and Arikara Indians and with Spanish settlements in the Southwest. They were a highly religious people for whom everyday actions and objects (*e.g.*, beadwork designs) had symbolic meanings. Their chief object of veneration was a flat pipe that was kept in a sacred bundle with a hoop or wheel. Like many other Plains tribes, they practiced the sun dance. Their social organization included age-graded military societies as well as men's shamanistic societies and other groups.

From early times the Arapaho were continually at war with the Shoshoni, the Ute, and the Pawnee. The southern Arapaho were for a long period closely associated with the southern Cheyenne; some Arapaho fought with the Cheyenne against Lieutenant Colonel George Armstrong Custer at Little Bighorn in 1876. In the Treaty of Medicine Lodge in 1867, the southern Arapaho were assigned a reservation in Oklahoma together with the Cheyenne, while the northern Arapaho were assigned a reservation in Wyoming with the Shoshoni. In the late 20th century there were about 2,000 Arapaho living on a reservation in Wyoming and more than 3,000 intermingled Arapaho and Cheyenne in Oklahoma.

arapaima (fish): *see* pirarucu.

'Ar'ar, town, northern Saudi Arabia, situated in the Northern region at an elevation of 1,854 feet (565 m). 'Ar'ar was developed in the early 1950s by seminomadic people who were attracted by water made available around the Trans Arabian Pipeline (Tapline). Agriculture and livestock raising are the main economic activities. Crops include alfalfa, dates, fruits, and vegetables. 'Ar'ar has a technical institute, a hospital, and an airport. Pop. (1992) 108,055.

Araraquara, city, in the highlands of central São Paulo state, Brazil, at 2,119 ft (646 m) above sea level on a tributary of the Rio Jacaré-Guaçu. Formerly known as Freguesia de São Bento de Araraquara, it was given town status in 1817 and was made the seat of a municipality in 1832. Araraquara's industries process sugarcane and coffee from the hinterland. Textiles, liquor, and furniture are also produced there. The city is accessible by railway, highway, and air from São Paulo, the state capital, 155 mi (250 km) southeast. Highways extend to other cities in São Paulo and Minas Gerais states. Pop. (2000 prelim.) 173,086.

Ararat, city, southwestern Victoria, Australia, on the northern flanks of the Pyrenees Range, near the Hopkins River. The community and a nearby peak (2,020 ft [616 m]) were named in 1840 by a sheep farmer who likened his settling there to the legendary resting of Noah's Ark on Mt. Ararat in Turkey after the Flood. Although gold was discovered in 1854, the rush of miners was delayed until 1857. Declared a borough in 1858 and a town in 1934, Ararat was made a city in 1950. It is now a commercial centre for a region of wheat and grape cultivation and livestock farming and lies on the main Adelaide-Melbourne rail line. It is connected to the harbours of Portland and Warrnambool by rail and is also the junction of the Pyrenees and Western highways. Industries include textile and timber mills, light engineering and rail workshops, cordial and butter plants, and a large postal relay facility. Notable annual events are a Highlands sports competition (New Year) and a nationally attended chess tournament (Queen's Birthday). Pop. (1991) 7,622.

Ararat, Mount, Turkish *AGRI DAGI*, extinct volcanic massif in extreme eastern Turkey overlooking the point at which the frontiers of Turkey, Iran, and Armenia converge. Its northern and eastern slopes rise from the broad alluvial plain of the Aras River, about 3,300 ft (1,000 m) above sea level; its southwestern slopes rise from a plain about 5,000 ft above sea level; and on the west a low pass

snowline varies with the season, retreating to 14,000 ft above sea level by the end of the summer. The only true glacier is found on the northern side of the Great Ararat, near its summit. The middle zone of Ararat, from 5,000 to 11,500 ft, is covered with good pasture grass and some juniper; there the local Kurdish population graze their sheep. Most of the Great Ararat is treeless, but Little Ararat has a few birch groves. Despite the abundant cover of snow, the Ararat area suffers from scarcity of water.

Ararat traditionally is associated with the mountain on which Noah's Ark came to rest at the end of the Flood. The name Ararat, as it appears in the Bible, is the Hebrew equivalent of Urardhu, or Urartu, the Assyro-Babylonian name of a kingdom that flourished between the Aras and the Upper Tigris rivers from the 9th to the 7th century BC. Ararat is sacred to the Armenians, who believe themselves to be the first race of humans to appear in the world after the Deluge. A Persian legend refers to the Ararat as the cradle of the human race. There was formerly a village on the slopes of the Ararat high above the Aras plain, at the spot where, according to local tradition, Noah built an altar and planted the first vineyard. Above the village Armenians built a monastery to commemorate St. Jacob, who is said to have tried repeatedly but failed to reach the summit of Great Ararat in search of the Ark. The village, the monastery of St. Jacob, and a nearby chapel of St. James were all totally destroyed by an earthquake and avalanche in 1840.

Local tradition maintained that the Ark still lay on the summit but that God had declared that no one should see it. In September 1829, Johann Jacob von Parrot, a German, made the first recorded successful ascent. Since then Ararat has been scaled by several explorers, some of whom claim to have sighted the remains of the Ark.

arartree, also called *ALERCE*, or *EVERGREEN TIMBER CONIFER* (*Tetraclinis articulata*), only species of the genus *Tetraclinis* of the cypress family (Cupressaceae), found in hot, dry areas of southeastern Spain, Malta, and North Africa.

A pyramidal tree 12 to 15 metres (about 40 to 50 feet) tall, the arartree has fragrant, brown

or reddish-brown wood that has long been popular for furniture and cabinetmaking. The tree also yields large quantities of sandarac, a fragrant resin.

Aras River, Russian *ARAKS*, Persian *RUD-E ARAS*, Turkish *ARAS NEHRİ*, Greek *ARAXES*, river rising south of Erzurum in the Bingöl Dağları (mountains) of Turkish Armenia; it flows eastward, forming for approximately 274 miles (441 km) the international boundary between Armenia on the north and Turkey and Iran on the south. Below Jolfā, a rail and road crossing in Iran, the stream emerges into a broad valley in which it crosses the Mugan Steppe. About 666 miles (1,072 km) long, it joins the Kura River in Azerbaijan 75 miles (121 km) from its mouth on the Caspian Sea.

Since a flood in 1897 a separate distributary (canalized since 1909) of the Aras also empties into the Caspian. The swift-flowing unnavigable Aras accounts for most of the sediment composing the Kura-Aras delta. Principal tributaries of the Aras are the Razdan, draining Lake Sevan and the Qareh Sū, flowing off the Kūhhā-ye Sabalān in northeastern Iranian Azerbaijan. On an island in the river stood Artaxata, capital of Armenia from 180 BC to AD 50. Some have held that the Aras River valley was the legendary Garden of Eden.

Arason, Jón (b. 1484, Eyjafjörður, Ice.—d. Nov. 7, 1550, Skálholt), poet and last Roman Catholic bishop in Iceland, remembered as a national as well as a religious hero.

The son of poor parents, he rose quickly to eminence in the church and was consecrated bishop of Hólar, the northern diocese of Iceland, in 1522. He administered his diocese prosperously until Christian III of Denmark began to impose Lutheranism on all his subjects. The two Icelandic bishops, Jón in the north and Ögmundur in the south, protested (1537). Ögmundur was deported by the Danes in 1541, but Jón continued his resistance. He captured the Lutheran bishop Marteinn and seized his see (1549-50) but was soon afterward taken by the King's agents and beheaded with two of his sons. Jón was the author of splendid religious and satirical poetry; he brought the first printing press to Iceland. His life was the subject of novels and plays by later Icelandic writers.

ārātrika (religious rite): see *ārti*.

Aratus (fl. c. 315-c. 245 BC, Macedonia), Greek poet of Soli in Cilicia, best remembered for his poem on astronomy, *Phaenomena*.

He resided at the courts of Antigonos II Gonatas, king of Macedonia, and Antiochus I of Syria. The *Phaenomena*, a didactic poem in hexameters, is his only completely extant work. Lines 1-757 versify a prose work on astronomy by Eudoxus of Cnidus (c. 390-c. 340), while lines 758-1154 treat of weather signs and show much likeness to Pseudo-Theophrastus' *De signis tempestatum*. The poem became immediately popular and provoked many commentaries, the most important of which is by Hipparchus (c. 150 BC) and is still extant. In form, the *Phaenomena* belongs to the Alexandrian school, but the author's Stoicism adds a strong note of seriousness. It enjoyed a high reputation among the Romans. Cicero, Caesar Germanicus, and Avienus translated it; the two last versions and fragments of Cicero's survive. One verse from the opening invocation to Zeus has become famous because it was quoted by St. Paul (Acts 17:28).

Aratus of Sicyon (b. 271 BC—d. 213), Greek statesman of the Hellenistic Period, a skilled diplomatist and guerrilla fighter who for many years was the leading spirit of the Achaean League.

After liberating Sicyon in 251, he established a democracy there and united it with the Achaean League for defense against Macedonia. As general of the league (a post he normally held each alternate year after 245), he captured Acrocorinth (243), defeated the Aetolians at Pellene (241), and pursued a policy of establishing democracies in the Peloponnese. With Aetolia as ally from 239, Sicyon repeatedly attacked Athens and Argos. Aratus brought Megalopolis (235) and Argos (229) into the league and helped liberate Athens from Macedonian rule (229). The hostility of Sparta, however, threatened these gains.

After being defeated twice by the Spartans under Cleomenes III, Aratus' League was saved by timely support from Antigonos Dossion (king of Macedonia, 227-221) in 224. A combined force of Achaeans and Macedonians defeated and dethroned Cleomenes in 222.

Mount Ararat from the Doğubayazıt plains, Turkey

Josephine Powell, Rome

separates it from a long range of other volcanic ridges extending westward toward the eastern Taurus ranges. The Ararat Massif is about 25 mi (40 km) in diameter.

Ararat consists of two peaks, their summits about 7 mi apart. Great Ararat, or Büyük Ağrı Dağı, which reaches an elevation of 16,854 ft above sea level, is the highest peak in Turkey. Little Ararat, or Küçük Ağrı Dağı, rises in a smooth, steep, nearly perfect cone to 12,782 ft. Both Great and Little Ararat are the product of eruptive volcanic activity. Neither retains any evidence of a crater, but well-formed cones and fissures exist on their flanks. Towering 14,000 ft above the adjoining plains, the snowcapped conical peak of the Great Ararat offers a majestic sight. The

On the accession of Philip V of Macedonia in 221, Aratus countered Aetolian aggression by obtaining the assistance of the Hellenic League. The resulting war ended in 217, and Aratus then began to resist Philip's anti-Roman policy and his interference in Messene. Although Philip was popularly believed to have had Aratus murdered, the Greek leader probably died of tuberculosis. His memoirs, no longer extant, provided an important source for Polybius' *History*.

Arauca, *departamento*, northeastern Colombia. It lies in the Orinoco River basin and is bounded north by Venezuela and south by the Casanare and Meta rivers. Arauca was given intendency status in 1955 and department status in 1991. It consists of llanos (plains) except in the extreme west, where it rises abruptly into the Cordillera Oriental of the Andes. It is drained by several tributaries of the Orinoco River. Cattle raising is the dominant economic activity; agricultural products include corn (maize), cacao, sugarcane, and rice. Furs, hides, rubber, and resins are shipped by river to Venezuela. Arauca town, the capital of the department, is connected by road northwest to San Cristóbal, Venezuela. Area 9,196 square miles (23,818 square km). Pop. (1992 est.) department, 96,972.

Arauca River, Spanish *RÍO ARAUCA*, western tributary of the Orinoco River, flowing through Venezuela and Colombia. It rises in the Cordillera Oriental of the Andes mountains, near the Venezuelan-Colombian border. Its easterly course is about 500 miles (800 km) long and forms part of the Venezuelan-Colombian boundary. The Arauca flows nearly parallel to the Apure and the Meta rivers to join the Orinoco about 60 miles (100 km) southeast of San Fernando de Apure, Venezuela. The level nature of the vast surrounding plains, combined with seasonal rainfall, results in widespread flooding during the rainy season (April to November).

Araucanía, region, southern Chile. It lies between the Bío-Bío and Toltén rivers and is bordered by Argentina on the east and the Pacific Ocean on the west. The region embraces the coastal mountain range, the fertile Central Valley, and the Andean cordillera.

It is the home of many Araucanian, or Mapuche, Indians, who maintained their independence under Spanish and Chilean authority until the late 19th century despite periodic campaigns to subdue them. The settlement of the conquered area by Chileans and Europeans, beginning with German colonists in the 1850s, has been encouraged by the national government.

Lake Villarrica with the Villarrica Volcano in the background, Araucanía region, Chile

Fenno Jacobs—Photo Researchers

Two partially navigable rivers, the Imperial and the Toltén, traverse southern Araucanía region from east to west. The cordilleran ridges and volcanoes at Tolguaca, Lonquimay, and Llaima and the forests, lakes, and hot springs at Tolguaca, Río Blanco, and Manzanares are prime scenic attractions. Tourism, however, ranks below farming (especially in wheat), cattle raising, and lumbering in economic importance. The region is heavily forested. The Pan-American Highway and the main north-south railway pass through Temuco, the regional capital. Area 12,300 square miles (31,858 square km). Pop. (1992 prelim.) 774,959.

Araucanian, any member of a group of South American Indians that are now concentrated in the fertile valleys and basins of south-central Chile, from the Bío-Bío River in the north to the Toltén River in the south.

Although the pre-Columbian Araucanians did not themselves recognize political or cultural unity above the village level, the Spanish distinguished three Araucanian populations geographically: the Picunche living in the north between the Choapa and Bío-Bío rivers, the Mapuche inhabiting the middle valleys, and the Huilliche dwelling in the south between the Toltén River and Chiloé Island. The first Araucanians encountered by the Spanish (c. 1536) were the Picunche, who had lived under Inca cultural influence or political domination since the 15th century. The Picunche were accustomed to outside rule and put up very little resistance to the Spanish. By the end of the 17th century, the Picunche had been assimilated into Spanish society and had vanished into the peasant population. The southernmost people, the Huilliche, were too few and too scattered to resist the Spanish for long. They, like the Picunche, vanished into the rural population of Chile.

At the time of the Spanish arrival in Chile, most of central Chile was settled by scattered populations of Mapuche (*q.v.*) farmers who grew corn (maize), beans, squash, potatoes, and other vegetables. They hunted, fished, and kept guinea pigs for meat; llamas were both pack animals and sources of wool for weaving fine fabrics that were traded with the Inca to the north. They had established metalsmithing and pottery-making traditions.

The Mapuche were more numerous and less tolerant of foreign domination than the Picunche of the north. In the face of the Spanish threat, the Mapuche formed widespread alliances above the village level, adopted the strategic use of horses in battle, and, in a series of conflicts called the Araucanian wars, successfully resisted Spanish and Chilean control for 350 years.

When Pedro de Valdivia's expedition occupied central Chile and founded Santiago in 1541, it met with strong resistance from the Mapuche. In 1550 Valdivia pressed southward and founded Concepción at the mouth of the Bío-Bío River, but in 1553 he and his followers were defeated by the Mapuche under Lautaro, a chief who had spent about two years in Valdivia's service. After Valdivia's disaster the Mapuche nearly captured Santiago, but the death of Lautaro on the battlefield and a smallpox epidemic among the Indians saved the colony. Another chief, Caupolicán, continued the fight until his capture by treachery and subsequent execution by the Spaniards in 1558. Thereafter the Spaniards pushed the Mapuche into the forest region south of the Bío-Bío, which remained the boundary between the two peoples for three centuries.

After the Chileans had annexed slices of Peruvian and Bolivian territory in the War of the Pacific (1879–84), they subdued the remaining Mapuche in the south; the Mapuche had begun to raid German-speaking settlements there in the late 1840s and had thus prevented further expansion of the white man into the Araucanian homeland. After their defeat by

the Chilean army, the Mapuche signed treaties with the Chilean government and were settled on reservations farther to the south. The Mapuche reservations were abolished in the 1980s, and the Mapuche now live in the hundreds of thousands on privately owned plots of former reservation land in Chile and in the towns and cities of Chile and Argentina. In contemporary usage, "Araucanian" is virtually synonymous with "Mapuche."

Araucaria, a genus of pinelike coniferous plants in the family Araucariaceae. The trees are magnificent evergreens, with apparently whorled branches and stiff, flattened, pointed leaves. They are found in Brazil and Chile, the Phoenix Islands, and Australia. The name of the genus is derived from Arauco, the name of a district in southern Chile where the trees were first discovered. *Araucaria araucana*, the Chile pine—or monkey puzzle tree (*q.v.*), as it was called because it was hard to climb—was introduced into Europe in the late 18th century and is extensively cultivated there. The tree grows to a height of 50 m (150 feet) in the cordilleras of Chile. The cones are from 20 to 22 cm (8 to 8.5 inches) broad and 17 to 19 cm (7 to 7.5 inches) long. The wood of the tree is hard and durable.

A. araucana, as well as other members of the genus, is cultivated on the Pacific coast of the United States and also in some cases in southern Florida. They are valued for the conspicuous growth habits that set them apart from nearly all other conifers. *A. excelsa*, the Norfolk Island pine (*q.v.*), a native of Norfolk Island and New Caledonia, finds some use as a houseplant during its sapling stage, because of the beauty of its symmetrically tiered growth. It is not often found out of doors in the United States, where *A. cunninghamii*, the Moreton Bay pine (*q.v.*), *A. bidwillii*, the bunya pine (*q.v.*), and *A. angustifolia*, the Paraná pine (*q.v.*) are more frequently found.

Arausio, Battle of (Oct. 6, 105 bc), the defeat of a Roman army by Germanic tribes near Arausio (now Orange in southern France). The Cimbri and the Teutoni had invaded the Roman province of Transalpine Gaul about 110 bc. The consul Gnaeus Mallius Maximus was sent from Italy in 105 with an army to reinforce that of the proconsul Quintus Servilius Caepio and began negotiations with the invaders; while these were going on, Caepio attacked the Cimbri. He was overwhelmed, and the consul's army, drawn into the fighting, was also destroyed. Although the Cimbri and the Teutoni did not advance into Italy, the disaster and the need to raise new forces led to the multiple consulships of Marius and to his army reforms.

'**Arava**, Ha- (Palestine): see Al-'Arabah, Wadi.

Arāvali Range, also called ARAVALLI RANGE, hill system of northern India, running northeasterly for 350 miles (560 km) through Rājasthān state. Isolated rocky offshoots continue to just south of Delhi. The series of peaks and ridges, with breadths varying from 6 to 60 miles (10 to 100 km) are generally between 1,000 and 3,000 feet (300 and 900 m) in elevation. The system is divided into two sections—the Sāmbhar-Sirohi ranges, taller and including Guru Peak on Mount Abu, the highest peak in the Arāvali Range (5,650 feet [1,722m]), and the Sāmbhar-Khetri ranges, consisting of three ridges that are discontinuous. The Arāvali Range is rich in natural resources (including minerals) and serves as a check to the growth of the western desert. It gives rise to several rivers, including the Banās, Lūni, Sakhi, and Sābarmati. Though heavily forested in the south, it is generally bare and thinly populated, consisting of large

areas of sand and stone and of masses of rose-coloured quartzite.

Āraṇiḍu DYNASTY, fourth and last dynasty of the Hindu empire of Vijayanagar in South India. Its founder was Tirumala, whose brother Rāma Rāya had been the masterful regent of the last ruler of the previous dynasty. Rāma Rāya's death at the Battle of Rakasa-Tangadi (also known as Tālikota) in 1565 and the subsequent destruction of Vijayanagar by the combined forces of the Muslim states of Bijāpur, Ahmadnagar, and Golconda was a deadly blow to the empire.

Tirumala, who became emperor in 1570, fixed his capital at Penugonda. But, beset by the Muslim powers, family disputes, and revolts of Hindu chiefs in the south, the Vijayanagar empire gradually dissolved by the first half of the 17th century.

Arawa, town, on the southeast coast of Bougainville Island, Papua New Guinea. Arawa is a planned suburban town on flatland near Arawa Bay. It was built to house the employees of Bougainville Copper Ltd., whose open-pit mine is located 16 miles (26 km) to the southwest at Panguna. The initial stage of the town was completed in 1972. The towns of Panguna, Arawa, Kieta, and Toniva are essentially one commercial and industrial entity involved in copper mining and the shipment of ore. Pop. (1984 est.) 14,900.

Arawak, American Indians of the Greater Antilles and South America who spoke languages of the Arawakan linguistic group.

The Antillean Arawak, or Taino, were agriculturists who lived in villages, some with as many as 3,000 inhabitants, and practiced slash-and-burn cultivation of cassava and corn (maize). The people were arranged in social ranks and gave great deference to theocratic chiefs. Religious belief centred on a hierarchy of nature spirits and ancestors, paralleling somewhat the hierarchies of chiefs. Despite the complex social organization, the Antillean Arawak were not given to warfare. They were driven out of the Lesser Antilles by the Carib shortly before the appearance of the Spanish.

The South American Arawak inhabited northern and western areas of the Amazon basin, where they shared the means of livelihood and social organization of other tribes of the tropical forest. They were sedentary farmers who hunted and fished, lived in small autonomous settlements, and had little hierarchical organization. The Arawak were found as far west as the foothills of the Andes. These Campa Arawak, however, remained isolated from influences of the Andean civilizations.

Arawakan languages, most widespread of all South American Indian language groups. Before the Spanish conquest, Arawakan languages were spoken in a number of disconnected areas from what is now Cuba and the Bahamas southward to the present Gran Chaco and the sources of the Xingu River in southern Brazil, and from the mouth of the Amazon River to the eastern foothills of the Andes. A great many communities still speak Arawakan languages in Brazil, and other groups of speakers are found in Peru, Colombia, Venezuela, Guyana, French Guiana, and Suriname. Taino, a now-extinct Arawakan language, once predominated in the Antilles and was the first Indian language to be encountered by Europeans. Spoken languages of importance are Goajiro in Colombia, Campa and Machiguenga in Peru, and Mojo and Bauré in Bolivia.

arawana (species *Osteoglossum bicirrhosum*), freshwater fish of tropical South America in the family Osteoglossidae (order Osteoglossiformes). Arawanas seldom reach lengths of

more than 60 cm (2 feet) but are regarded as superb sports fish and highly edible. In appearance they have large scales and long dorsal and anal fins that almost join with the tail fin. The lower jaw angles upward to a point above the eyes, and two long, filamentous barbels extend forward from the chin. Arawanas are believed to be mouth brooders, the female carrying the eggs in her mouth until they hatch.

arba' kanfot, also spelled ARBA' KANFOTH (Hebrew: "four corners"), also called ṬALLIT QATĀN, or TALLITH KATAN ("small shawl"), Jewish religious garment that apparently came into use during times of persecution as a substitute for the larger and more conspicuous prayer shawl (*tallit*). Both garments have fringes (*tzitzit*) on the four corners, increasing the likelihood that one was a conscious imitation of the other. The *tallit*, however, generally falls across the head, neck, and shoulders, while the *arba' kanfot* has an opening for the head (like a poncho), so that it can be worn beneath the upper garments. Orthodox male Jews, including children, wear the *arba' kanfot* during the day to fulfill the requirement of wearing fringes (Numbers 15:37-41) as reminders of God's commandments.

Arbeau, Thoinot, original name JEHAN TABOUROT (b. March 17, 1519/20, Dijon, Fr.—d. 1595, Langres), theoretician and historian of the dance, whose *Orchésographie* (1588) contains carefully detailed, step-by-step descriptions of 16th-century and earlier dance forms.

Ordained a priest in 1530, he became a canon at Langres (1574), where he was encouraged to pursue his studies by the Jesuits, who considered dance to be educationally important.

Orchésographie is written in the form of a dialogue between the author and a student. Such dances as the pavane, gavotte, and allemande are not only exactly described but also usually illustrated and directly associated with their musical forms. The book also outlines principles that, more than a century later, formed the basis of the five fundamental positions of the feet in classical ballet. In addition to its wealth of technical information, it is an interesting account of social behaviour and manners.

ARBED SA, in full ACIÉRIES RÉUNIES DE BURBACH-EICH-DUDELANGE, integrated steel-producing company that is the largest industrial concern in Luxembourg.

The company was formed in 1911 through the merger of Les Forges d'Eich, Le Gallais, Metz et Cie. (established in 1838 under a different name); La Société Anonyme des Mines du Luxembourg et Forges de Sarrebruck (1856), and La Société Anonyme des Hauts Fourneaux et Forges de Dudelange (1882). Since then the company has formed subsidiaries in Europe and South America.

Through its subsidiary and affiliate companies, the company engages in every step of steel production and processing, from the extraction of coal and iron ore (from its own mines) to the fabrication of highly specialized steel products, including the whole range of rolled-steel products and some finished products, especially wire. In 1980 it entered into a joint venture with Bethlehem, an American steel company, to produce Galvalume, a sheet steel product patented by Bethlehem, for distribution to Europe and abroad.

Arbenz (Guzmán), Jacobo (b. Sept. 14, 1913, Quezaltenango, Guat.—d. Jan. 27, 1971, Mexico City, Mex.), soldier, politician, and president of Guatemala (1951-54) whose nationalistic economic and social reforms alienated conservative landowners, conservative el-

ements in the army, and the U.S. government and led to his overthrow.

The son of a Swiss pharmacist who had emigrated to Guatemala, Arbenz was educated at the National Military Academy of Guatemala. He joined a group of leftist army officers that overthrew the Guatemalan dictator Jorge Ubico in 1944, and in 1949 he was the minister of war in Juan José Arévalo's government. In March 1951 he succeeded to the presidency, supported by the army and the left-wing political parties, including the Guatemalan Communist Party.

Arbenz, 1950

By courtesy of the Organization of American States

Arbenz made agrarian reform the central project of his administration. This led to a clash with the largest landowner in the country, the U.S.-based United Fruit Company, whose idle lands he tried to expropriate. He also insisted that the company and other large landowners pay more taxes. As the reforms advanced, the U.S. government, cued by Secretary of State John Foster Dulles, became increasingly alarmed, fearing the threat to sizable American banana investments and to U.S. bank loans to the Guatemalan government as well. A public-relations campaign painted Arbenz as a friend of communists (whose support he undoubtedly had); and the U.S. Central Intelligence Agency, working in Honduras and El Salvador, helped to organize a counterrevolutionary army of exiles led by Colonel Carlos Castillo Armas. Exaggerations of the size of the invading force panicked the capital; the Guatemalan army refused to fight for Arbenz, and he was forced to resign (June 27, 1954) and go into exile. Armas, who soon became president, reversed most of the reforms of the previous decade and offered generous concessions to foreign investors.

In 1957 Arbenz moved to Uruguay and then to Cuba and later returned to Mexico.

Arber, Agnes, née ROBERTSON (b. Feb. 23, 1879, London—d. March 22, 1960, Cambridge, Cambridgeshire, Eng.), botanist noted chiefly for her studies in comparative anatomy of plants, especially monocotyledons.

She attended the universities of London (B.Sc., 1899; D.Sc., 1905) and Cambridge (M.A.) and in 1909 married Edward Alexander Newell Arber, a paleobotanist who had been her teacher at Cambridge. In 1946 she became the first woman botanist to be named a fellow of the Royal Society.

Her first and perhaps most widely read work is *Herbals, Their Origin and Evolution* (1912), an account of herbals published between 1470 and 1670. Her studies in comparative anatomy include *Water Plants: A Study of Aquatic Angiosperms* (1920), *Monocotyledons: A Morphological Study* (1925), and *The Gramineae: A Study of Cereal, Bamboo and Grass* (1934). Later works reflect her interest in philosophy: *The Natural Philosophy of Plant Form* (1950), *The Mind and the Eye: A Study of the Biologist's Standpoint* (1954), and *The Manifold and the One* (1957).

Arber, Edward (b. Dec. 4, 1836, London—d. Nov. 23, 1912, London), scholar whose editing, and publication at reasonable prices, of Elizabethan and Restoration texts first made detailed study of them possible to the ordinary student.

An Admiralty clerk, he studied literature and entered academic life, serving as professor of English at Birmingham from 1881 to 1894. His editions of many texts remain the only ones easily accessible. His *English Reprints*, 30 vol. (1868–71), began with a sixpenny edition of Milton's *Areopagitica*. Later series include the important *English Garner*, 8 vol. (1877–96), and *The English Scholar's Library of Old and Modern Works*, 16 vol. (1878–84). Also valuable are his *Transcript of the Registers of the Company of Stationers of London, 1554–1640 A.D.* (*The Stationers' Register*, 5 vol., 1875–94) and *The Term Catalogues, 1668–1709 A.D.*, 3 vol. (1903–06), edited from booksellers' quarterly lists.

Arber, Werner (b. June 3, 1929, Gränichen, Switz.), Swiss microbiologist, corecipient with Daniel Nathans and Hamilton Othanel Smith (*qq.v.*) of the United States of the Nobel Prize for Physiology or Medicine for 1978. All three were cited for their work in molecular genetics, specifically the discovery and application of enzymes that break the giant molecules of deoxyribonucleic acid (DNA) into manageable pieces, small enough to be separated for individual study but large enough to retain bits of the genetic information inherent in the sequence of units that make up the original substance.

Arber studied at the Swiss Federal Institute of Technology in Zürich, the University of Geneva, and the University of Southern California. He served on the faculty at Geneva from 1960 to 1970, when he became professor of microbiology at the University of Basel.

During the late 1950s and early '60s Arber and several others extended the work of an earlier Nobel laureate, Salvador Luria, who had observed that bacteriophages (viruses that infect bacteria) not only induce hereditary mutations in their bacterial hosts but at the same time undergo hereditary mutations themselves. Arber's research was concentrated on the action of protective enzymes present in the bacteria, which modify the DNA of the infecting virus—*e.g.*, the restriction enzyme, so-called for its ability to restrict the growth of the bacteriophage by cutting the molecule of its DNA to pieces.

Arbil (Iraq): *see* Irbil.

arbitrage, business operation involving the purchase of foreign exchange, gold, financial securities, or commodities in one market and their almost simultaneous sale in another market, in order to profit from price differentials existing between the markets. Opportunities for arbitrage may keep recurring because of the working of market forces. Arbitrage generally tends to eliminate price differentials between markets. Whereas in less developed countries arbitrage can consist of the buying and selling of commodities in different villages within the country, in highly developed countries the term is generally used to refer to international operations involving foreign-exchange rates, short-term interest rates, prices of gold, and prices of securities.

Foreign-exchange arbitrage, confined to spot-exchange markets—in which exchange is bought and sold for immediate delivery—may involve two or more exchange centres (two-point arbitrage or multiple-point arbitrage). For example, assume that Country A's sovereign is exchanging at two to the dollar in New York City, while Country B's franc is valued at five to the dollar. Logically, Country A's sovereign should exchange at two sovereigns to five francs. But for some reason banks in Country B are paying four francs for

two sovereigns. A New York City operator with \$100,000 at his disposal may then make three moves: (1) buy 500,000 francs in New York City in the form of an electronic transfer to his account in Country B; (2) instruct his correspondent in Country B to use a similar amount of francs to buy 250,000 of Country A's sovereigns at the going rate of four francs for two sovereigns, in the form of an electronic transfer to his account in Country A; and (3) sell the same amount of sovereigns in New York City at two to the dollar for a total of \$125,000, or a profit of \$25,000. Foreign exchange operators will continue to do this until the heavy demand for francs in New York City has raised their price and eliminated the profit.

Opportunities for interest arbitrage arise when the money rates differ among countries. Gold arbitrage and securities arbitrage operate in principle very much like commodity arbitrage in the domestic market, except that in the two former cases exchange rates are important, either because funds must be remitted abroad for the operation or because the proceeds must be brought home at the end of the operation.

With the increase in corporate mergers and takeovers in the 1980s, a form of stock speculation called risk arbitrage arose. It was based on the fact that a company or corporate raider, when trying to merge with or purchase a corporation, usually must offer to buy that company's stock at a price 30 or 40 percent higher than the current market price, and the target company's price usually rises to near the offered price on the open market once the takeover attempt has been publicly announced. Risk arbitrageurs try to identify in advance those companies that are targeted for a takeover; they then buy blocks of the company's stock before a tender offer has been announced and sell that stock after the merger or takeover has been completed, thus realizing large profits. The risk is that the merger or takeover attempt will not succeed, in which case the stock price usually falls back down again, thus incurring large losses for the arbitrageur.

Risk arbitrageurs' activities can either facilitate or hinder the efforts of corporate raiders and investment banks to consummate a takeover attempt, and there are temptations for those parties to communicate advance knowledge of their takeover attempts to arbitrageurs, who can then speculate in the target company's stock with a minimum of risk. This is a form of insider trading and is illegal in the United States and some other countries. Such was the case with the best known American arbitrageur, Ivan Boesky, who, while under government investigation in 1986, admitted that he had engaged in some highly profitable insider trading and was fined \$100,000,000 as a consequence.

arbitration, a legal method of settling disputes between parties outside ordinary court procedures by deferring to a mutually agreed-upon third party who has the authority to determine an "award," a legally binding decision.

A brief treatment of arbitration follows. For full treatment, *see* MACROPAEDIA: Judicial and Arbitration Systems.

Arbitration is most commonly resorted to in cases involving commercial disputes, but it is also practiced in resolving disputes between labour unions and management and in international controversies between sovereign states where diplomatic channels are not sufficient.

The third party, or arbitrator, may be a single individual or a body known as a tribunal chosen by the parties and knowledgeable in the area of dispute. In general, awards are based on the existing laws related to the contracts or issues in dispute as they are understood

and agreed upon in advance by the parties concerned and by the arbitrator.

Commercial arbitration. Commercial arbitration began in medieval Europe as a means for settling disputes between individual merchants and became an increasingly favoured method as courts of law were given the power to enforce arbitration agreements and awards. Today, parties engaged in arbitration usually must agree in advance to accept a decision as irrevocable, and the courts provide a means for securing awards from recalcitrants.

Arbitration is often resorted to as a substitute for lengthy court procedures because it has the advantage of avoiding costly litigation, resolving disputes faster, and allowing privacy for the disputants. The disadvantage is that it is difficult to set guidelines; therefore the outcome is often less predictable than a court decision.

Labour-management arbitration. Unlike commercial arbitration, labour arbitration is not a method practiced in lieu of court procedures, but rather it is a technique for settling or avoiding strikes. It has two aspects, arbitration of rights and arbitration of interests.

Arbitration of rights concerns a dispute over the application of a current contract between labour and management and is a more prevalent practice in the United States than in other countries. The arbitrator may be chosen at the time of dispute or named "umpire" as part of the collective-bargaining agreement for the duration of the contract. The arbitrator's decision is legally binding. Further, the procedures used in arbitration do not have to comply with court procedures, especially in the areas related to burden of proof and presentation of evidence. The courts are rarely called upon to review an arbitrator's decision.

Arbitration of interests refers to the process of settling disputes in the formation of a new contract when labour and management have been unable to come to an agreement by any other method. It is becoming a more favoured method in industries and services that involve such essential public interests as transportation and medical services.

International arbitration. International arbitration has a long history dating back to the civil wars between the ancient Greek city-states. Its modern development begins with the Jay Treaty of 1794 between Great Britain and the United States to settle claims stemming from the American Revolution. In the Hague Conference of 1899, a basis for peaceful settlement of disputes by international arbitration was established in a convention that was revised in a conference in 1907. Since that time there have been several multilateral international treaties that provide for arbitration in disputes in which all other avenues of reconciliation have failed. Among these treaties are provisions adopted by the General Assembly of the United Nations in 1949.

There are still great difficulties in international arbitration because sovereign states prefer to maintain great flexibility in determining their actions, thus precluding a definite body of rules that can be universally applied. The greatest impediment to resolving disputes peacefully through international arbitration is the infrequency of its practice. The custom of most nations is to reject arbitration as a method if there is no assurance of a favourable outcome or if either party is unwilling to comply with an unfavourable decision.

Arbogast (d. Sept. 8, 394), barbarian general of the Roman Empire, the first to establish a Roman nominee of his own as a puppet emperor.

Probably of Frankish descent, he rose to the rank of *magister equitum* ("master of the cavalry") in the Western Roman army and was

sent by the emperor Gratian, in 380, to assist the Eastern ruler Theodosius against the Goths in Thrace. He remained in the service of Theodosius. In 388, after the defeat in Italy of the usurper Magnus Maximus by Theodosius, Arbogast recovered Gaul for the Western emperor Valentinian II from Maximus' son, Flavius Victor. The following year Arbogast pacified the Rhine frontier, imposing a treaty on the Frankish leaders Marcomer and Sunne, who had invaded Gaul in 384.

By 391 the general had become all-powerful in Gaul as *comes* ("count") and regent. When Valentinian attempted to dismiss him, Arbogast declared that only Theodosius possessed the power to do so. On May 15, 392, Valentinian died at Vienna (modern Vienne, Fr.) in circumstances suggestive of murder instigated by Arbogast. Proclaiming Eugenius, a professor of rhetoric, as emperor in the West, Arbogast—who admired the Roman Republic and despised the quarrels between Roman Catholic and Arian Christians—set about restoring paganism. In the winter of 393–394, he conducted a successful campaign against the Riparian Franks, the Chamavi, and along the Rhine, but the following May, Theodosius marched west to suppress the pagan revolution. A two-day battle ended in victory for Theodosius. Eugenius was beheaded; Arbogast committed suicide.

arbor, garden shelter providing privacy and partial protection from the weather. The name is used for a modest garden building of any material; it has been applied to examples as varied as a wrought-iron shelter at Melbourne

Arbor, Moffat-Ladd Garden, Portsmouth, N.H.
Douglas Armsden

Hall, Derbyshire, Eng., and houses constructed of pebbles, brick, or masonry. It is more correctly limited to rustic garden houses that are made up entirely of interlaced branches of growing trees and shrubs or of greenery trained over a light framework of wood or metal. If there is a distinction between an arbor and a bower, it is that the bower is an entirely natural recess whereas an arbor is only partially natural.

arboriculture, cultivation of trees, shrubs, and woody plants for shading and decorating. Arboriculture includes propagating, transplanting, pruning, applying fertilizer, spraying to control insects and diseases, cabling and bracing, treating cavities, identifying plants, diagnosing and treating tree damage and ailments, arranging plantings for their ornamental values, and removing trees. The well-being of individual plants is the major concern of arboriculture, in contrast to such related fields as silviculture and agriculture, in which the major concern is the welfare of a large group of plants as a whole.

The basic principles and objectives of arboriculture are of ancient origin. Early Egyptians transplanted trees with a ball of earth and orig-

inated the practice of shaping the soil around a newly planted tree to form a saucer to retain water, both still practiced. About 300 BC the Greek philosopher Theophrastus wrote *Peri phytōn historia* ("Inquiry into Plants"), in which he discussed transplanting of trees and the treatment of tree wounds. Virgil's *Georgics* portrays Roman knowledge of tree culture. The English horticulturist John Evelyn, in his *Sylva, or a Discourse of Forest-trees, and the Propagation of Timber* (1664), offered advice on pruning, insect control, wound treatment, and transplanting.

Trees or plants may be propagated by seeding, grafting, layering, or cutting. In seeding, seeds are usually planted in either a commercial or home nursery in which intensive care can be given for several years until the plants are of a size suitable for transplanting on the desired site. In soil layering, the shoots, or lower branches of the parent plant, are bent to the ground and covered with moist soil of good quality. When roots have developed, which may require a year or more, the branch is severed from the parent and transplanted. In an alternative technique, air layering, the branch is deeply slit and the wound covered by a ball of earth, moss, or similar material. The ball, enclosed in a divided pot supported from underneath, or in a sturdy paper cone, is kept moist. As in soil layering, the branch is severed and transplanted after roots have developed. Root cuttings can be used for propagating trees that do not normally produce roots from stems. Tree species such as willow and poplar that sucker, or send up shoots readily, are usually propagated from stem cuttings. Cuttings are made from deciduous plants during dormancy, preferably from the terminal growing shoots of the current season. Pieces 6 to 10 inches (15 to 25 centimetres) long with two or more buds are tied in bundles and stored in damp sand or moss for callus formation before planting in prepared beds. Root formation may be stimulated by application of growth-promoting chemicals or growth hormones.

In treating tree-trunk wounds in which large areas of bark are torn away, the bark around the wound is trimmed back to sound tissue and, at the top and bottom of the injury, trimmed to form a pointed ellipse of the wound area. The exposed wood is covered with wound dressing material, protecting it from wood decay fungi.

Flexible cables (guys) or rigid braces are used to support recently transplanted trees until the roots become established, or to lessen the danger that a tree with a weakened root system will be blown over by the wind; bracing is also used to support unduly long or heavy branches, to prevent splits developing at branch forks, or to permit healing of splits already developed.

Cavities in trunks, caused by decay-inducing fungi, may be treated with antiseptic dressing and left open, with drains installed at the bottom, or filled with concrete or other material after removal of the decayed wood. *See also* graft; pruning; transplant.

arborvitae (Latin: "tree of life"), any of six species of the genus *Thuja*, resinous, evergreen ornamental and timber conifers of the cypress family (Cupressaceae), native to North America and eastern Asia. A closely related genus is false arborvitae (*q.v.*).

Arborvitae are trees or shrubs, usually pyramidal in habit, with thin, scaling outer bark and fibrous inner bark, horizontal or ascending branches, and characteristically flattened, spraylike branchlet systems. Each branchlet has four rows of tiny, scalelike leaves. Juvenile leaves are much longer and needlelike and in some species may persist along with the mature foliage.

Male and female reproductive structures (cones) are borne at the tips of different branchlets of the same tree, the male cones

rounded and reddish or yellowish, the female very small and green or tinged with purple. Mature cones are solitary, egg shaped or oblong, 8 to 16 millimetres (about ½ inch) long, with 4 to 6 (but sometimes 3 or as many as 10) pairs of thin, flexible scales that terminate in thickened ridges or processes.

The oriental, or Chinese, arborvitae (*T. orientalis*), a popular ornamental native to Asia, is a gracefully symmetrical shrub about 10 metres (33 feet) tall. Some authorities have assigned it to a separate genus (*Biota*) because of distinctions such as its erect branches, vertically arranged, fanlike branchlet systems, and six to eight hook-tipped cone scales.

Yellowish or reddish-brown arborvitae wood is soft, light in weight but very durable, fragrant, and easily worked. The giant arborvitae (*q.v.*; *T. plicata*) is the most important timber-producing species, but the wood of the American arborvitae (*q.v.*; *T. occidentalis*) is also frequently used.

arbovirus, acronym derived from *arthropod-borne virus*, a group of viruses that develop in arthropods (chiefly blood-sucking mosquitoes and ticks), in which they cause no apparent harm, and are subsequently transmitted by bites to vertebrate hosts, in which they establish infections and complete their growth cycle. The group includes the agents responsible for yellow fever, equine encephalitis, dengue, and louping ill (*qq.v.*). The spheroidal virus particle is enveloped in a fatty membrane, varies in size from 30 to 100 nanometres (nm; 1 nm = 10⁻⁹ metre) across, and contains ribonucleic acid (RNA). Some regions of the tropics, locally rich in arboviruses, present a complicated picture of the ecological net of arthropod carrier, vertebrate host, and the environment.

The arbovirus group is a diverse assemblage, the members of which are often assigned to viral families as they become better known, *e.g.*, as togavirus (family Togaviridae) and rhabdovirus (family Rhabdoviridae).

Arbroath, royal burgh (town), North Sea fishing port, and holiday resort, Angus council area and historic county, Scotland. Arbroath Abbey, once the wealthiest in Scotland, was founded in 1178 by King William I (the Lion) of Scotland, who is buried there. The Declaration of Arbroath, asserting the independence of Scotland following Robert the Bruce's victory over the English at Bannockburn (1314), was composed by the Scottish Parliament in Arbroath Abbey and sent to the pope at Avignon, France. Engineering, textile manufacturing, oil-related industries, boatbuilding, food processing, and tourism are the town's main industries. The town is noted for its smoked haddock. Pop. (1991) 23,474.

Arbuckle, Fatty, byname of ROSCOE CONKLING ARBUCKLE (b. March 24, 1887, Smith Center, Kan., U.S.—d. June 30, 1933, New York City), early star of silent comedy motion pictures, who was the central figure in notorious trials for manslaughter.

A veteran of vaudeville and carnivals, Arbuckle became a screen extra for the Selig Polyscope Company in 1908 and performed in many one-reel comedies. He was an agile comedian in spite of his 320-pound weight and soon rose to star status in Mack Sennett's studio. He was for a time a member of Sennett's Keystone Kops and appeared with Chester Conklin, Charlie Chaplin, and other silent-film stars.

By 1917 Arbuckle had formed his own production company and was instrumental in the development of the career of Buster Keaton. At the peak of his popularity his career ended when he was accused of sexually assaulting a starlet who subsequently died of complications from the alleged attack. Arbuckle was eventually acquitted of a manslaughter charge but was forced by the negative publicity

into retirement, and his films were banned. Through the aid of friends he was able to reenter the film industry as a director under the pseudonym of William B. Goodrich. One result of the case was the institution of the Hays Office, which was designed to regulate and censor the movie industry.

Arbus, Diane, née NEMEROV (b. March 14, 1923, New York, N.Y., U.S.—d. July 26, 1971, New York City), American photographer, best known for her compelling, often disturbing, portraits of people from the edges of society.

Arbus was the daughter of a wealthy businessman and the sister of the poet and critic Howard Nemerov. At the age of 18 she rejected a college education and married Allan Arbus (divorced 1969), who worked in her father's fur and ladies' clothing store. Together they worked as fashion photographers until 1957. In the mid-1950s, under the influence of her mentor, Lisette Model, Arbus began regularly to photograph all manner of people and events in the city and its environs. In 1960 she did her first photo-essay, for *Esquire* magazine, in which she effectively juxtaposed high life with squalor. Thereafter she made a living as a free-lance photographer and photography instructor until her death by suicide.

"Untitled #6," gelatin silver print by Diane Arbus, 1970-71; in the Robert Miller Gallery, New York City

© The Diane Arbus Estate

Formal elements of Arbus' provocative later work include the use of a square format, which, among other effects, emphasizes the significance for her of the subject over the photographer's composition, and the use of flash lighting, which gives an added dimension of theatricality and surrealism. Her own evident intimacy with the extraordinary subjects of her photos—including nudists, sideshow performers, and transvestites—resulted in images that assumed the sympathy and collusion of the viewer and never failed to elicit strong response.

A collection of her photos was published in 1972, in connection with a major exhibition of her work at the Museum of Modern Art in New York City; the exhibition subsequently toured the United States.

Arbuthnot, John (b. April 1667, Inverbervie, Kincardine, Scot.—d. Feb. 27, 1735, London, Eng.), Scottish mathematician, physician, and occasional writer, remembered as the close friend of Jonathan Swift, Alexander Pope, and John Gay and as a founding member of their famous Scriblerus Club, which aimed to ridicule bad literature and false learning.

After taking a medical degree in 1696 at the University of St. Andrews, Arbuthnot became a fellow of the Royal Society in 1704 and was one of Queen Anne's physicians from 1705 until her death. Though he published mathematical and other scientific works, his fame rests on his reputation as a wit and on his satir-

ical writings. He wrote a political allegory dealing with the political jockeying of the British, French, Spanish, and Dutch that led up to the Treaty of Utrecht (1713). Published in five pamphlets, the earliest appearing in 1712, it was collected in 1727 under the composite title *Law is a Bottom-less Pit; or, The History of John Bull*, and it established and popularized for the first time the character who was to become the permanent symbol of England in cartoon and literature.

The other satire in which Arbuthnot had an important share was the *Memoirs of Martinus Scriblerus*, a mocking exposure of pedantry, first published in the 1741 edition of Pope's works but largely written as early as 1713-14 by the members of the Scriblerus Club. The other members of the club acknowledged Arbuthnot as the chief contributor and guiding spirit of the work. Arbuthnot was indifferent to literary fame, and many of his witticisms and ideas for satires were later developed by and credited to his more famous literary friends.

Arbutus, genus of about 14 species of broad-leaved evergreen shrubs or trees, of the heath family (Ericaceae), characterized by white or pink flowers in loose, terminal clusters and by many-seeded, fleshy, red or orange berries; the leaves are alternate and stalked. The plants are native to southern Europe and western North America. *A. menziesii* and *A. unedo* are cultivated as ornamentals.

Arbutus menziesii, variously known as the madrona, Pacific madrona, laurelwood, and Oregon laurel, occurs in western North America from British Columbia to California. It grows about 23 m (75 feet) tall. The dark, oblong, glossy leaves are from 5 to 15 cm (2 to 6 inches) long and are coloured grayish green beneath. The whitish flowers grow in pyramidal clusters 7-23 cm tall. As the tree grows, the old bark peels off, revealing reddish or cinnamon-coloured bark beneath.

Arbutus unedo is the strawberry tree, native to southwestern Europe but introduced into warm regions of western North America. It grows from 3 to 9 m tall, with one to several trunks, and has lustrous elliptic or oblong leaves about 9 cm long. The branches are sticky and hairy. The white or pinkish flowers droop in clusters, and the fruit, edible but tasteless, resembles a strawberry in size and colour.

The trailing arbutus belongs to the genus *Epigaea*.

Arc de Triomphe, in full ARC DE TRIOMPHE DE L'ÉTOILE, the largest triumphal arch in the world, and one of the best-known commemorative monuments of Paris, France. The arch stands at the centre of the Place Charles de Gaulle (formerly the Place de l'Étoile), which is the western terminus of the Avenue des Champs-Élysées. The arch is 164 feet (50 m) high and 148 feet (45 m) wide. It was initiated by Napoleon Bonaparte and was designed by J.-F.-T. Chalgrin. Construction of the arch began in 1806, though work was not completed until 1836. Decorative relief sculptures celebrating Napoleon's victorious military cam-

paigns were executed on the arch by François Rude, Jean-Pierre Cortot, and Antoine Etex. Beneath the arch lies France's Tomb of the Unknown Soldier.

arc, electric: see electric arc.

arc furnace, type of electric furnace (*q.v.*) in which heat is generated by an arc between carbon electrodes above the surface of the material (commonly a metal) being heated.

arc lamp, device for producing light by maintaining an electric arc across a gap between two conductors; light comes from the heated ends of the conductors (usually carbon rods) as well as from the arc itself. Arc lamps are used in applications requiring great brightness, as in searchlights, large film projectors, and floodlights. The term arc lamp is usually restricted to lamps with an air gap between consumable carbon electrodes, but fluorescent and other electric discharge lamps generate light from arcs in gas-filled tubes. Some ultraviolet lamps are of the arc type.

Sir Humphry Davy constructed the first arc lamp (1807), using a battery of 2,000 cells to create a 100-millimetre (4-inch) arc between two charcoal sticks. When suitable electric generators became available in the late 1870s, the practical use of arc lamps began. The Yablochkov candle, an arc lamp invented by the Russian engineer Paul Yablochkov, was used for street lighting in Paris and other European cities from 1878.

arc welding, use of a sustained luminous electrical discharge (arc) as a source of heat for melting the filler metal (welding rod) and the metals being welded. See welding.

arcade, in architecture, a series of arches carried by columns or piers, a passageway between arches and a solid wall, or a covered walkway that provides access to adjacent shops. An arcade that supports a wall, a roof, or an entablature gains enough strength from lateral thrusts that each individual arch exerts against the next to carry tremendous weight loads and to stretch for great distances.

Ancient aqueducts show an early use of the arcade. Later Roman builders used the pattern to construct large wall surfaces: the Colosseum, with 80 arcaded openings on each of its three stories, is one of the finest examples of this architectural form.

An arcade with pilasters, or engaged columns attached to piers carrying an entablature, is known as a Roman arcade. During the late empire this was replaced by arches that rested on the capitals of a row of columns, a style that was standard in the Romanesque and Gothic periods and that was revived and widely used during the Renaissance (*e.g.*, Filippo Brunelleschi's Ospedale degli Innocenti in Florence). In Byzantine arcades, spreading blocks called impost blocks were often placed between the capitals and arches, a style used widely throughout the East.

Arcade, Ospedale degli Innocenti, Florence (1419-26), by Filippo Brunelleschi

Alman—Art Resource

As a purely decorative element, arcades are used in Gothic churches to divide the nave wall into three horizontal parts—the arcade at floor level, the triforium above, and the clerestory at the top—as well as to frame sculpture on the facade (as can be seen, with excellent effect, on Amiens cathedral). To a lesser extent, Baroque architects made use of this form of the arcade, and it remained a significant element in Europe and America throughout the 19th century.

As a covered passageway, the arcade has been in use since Roman times. Medieval cloisters often featured arcades, and most Islamic mosques include arcaded courtyards. In Renaissance towns such as Bologna, arcades line shops and other buildings. Middle Eastern bazaars are often arcaded rows of shops, and the design of modern enclosed or partially enclosed shopping centres has made the use of the label, if not the original form, common in the United States.

Arcadelt, Jacob, Arcadelt also spelled ARCADEL, ARCHADEL, ARCHADENTE, ARCHADET, or HARCHADELT, Jacob also spelled JACQUES, or JAKOB (b. c. 1500, Liège? [now in Belgium]—d. Oct. 14, 1568, Paris?, France), composer who helped establish the musical form of the madrigal.

Arcadelt was a singer and later a choirmaster in the papal chapel in Rome (1539–49), and he subsequently spent time in France and again in Italy. He entered the service of Charles, duc de Guise, in 1555 and in 1557 was a member of the French royal chapel.

Arcadelt's reputation rests on about 120 chansons and more than 200 Italian madrigals. With two contemporary composers, Costanzo Festa and Philippe Verdelot, he set the style for a generation of madrigal composers. He favoured four-voiced composition, and his secular music owes much to the simple declamation and tuneful treble melody of the frotola, a popular Italian song genre. The simple clarity of his style influenced Palestrina and Cipriano de Rore. Arcadelt also published about 20 motets and 3 masses.

Arcadia, Modern Greek ARKADHÍA, mountainous region of the central Peloponnesus of ancient Greece. The pastoral character of Arcadian life together with its isolation partially explains why it was represented as a paradise in Greek and Roman bucolic poetry and in the literature of the Renaissance. The region is not exactly coextensive with the present-day *nomós* (department) of Arkadhía, which extends on the east to the Gulf of Argolis. The capital of the *nomos* is Trípolis.

The plateau of Arcadia, with basins at elevations of 1,650 to 3,300 feet (500 to 1,000 m), is bounded on the north by the Érimanthos and Killíni mountains and is itself divided by numerous subsidiary ranges. In eastern Arcadia the ranges enclose a series of plains drained only by underground channels. The western plateau is more open, with isolated mountains through which wind the Alpheus River and its tributaries. One of those, the Ládhon, provides hydroelectric power at a dam and reservoir. A region of erratic rainfall, Arcadia has a few vineyards but no olive trees. There are patches of oak forest, but the eastern reaches are drier and less verdant.

In ancient times Arcadia was bounded on the north by Achaea, on the south by Messenia and Laconia, on the east by Argolis, and on the west by Elis. It was thus cut off from the coast on all sides. Because it was isolated from the rest of mainland Greece, Arcadia was not occupied by the Dorians during their invasion of Greece (1100–1000 BC), and it retained a dialect that still resembles that of the Greeks who settled in Cyprus (the Arcado-Cypriot dialects). By 550 BC Tegea, Mantinea, and the

smaller Arcadian towns had all accepted forced alliances with Sparta, and discord between the towns subsequently prevented them from uniting against Spartan power. Most Arcadians remained faithful to Sparta during the Peloponnesian War (431–404 BC), though in 370 BC the Arcadian League, with its capital at Megalopolis, united the Arcadians for a few decades before internal discord paralyzed their confederation. In Roman times Arcadia fell into decay. Area 1,706 square miles (4,419 square km). Pop. (1991) *nomós*, 105,309.

Arcadia, city, Los Angeles county, California, U.S. It lies at the base of the San Gabriel Mountains. Laid out in 1888 on lands of Rancho Santa Anita and developed by E.J. ("Lucky") Baldwin, it was named for the district in ancient Greece said to symbolize pastoral beauty. An early agricultural centre, it was promoted as a residential community. Freeway connections to Los Angeles, 15 miles (24 km) southwest, aided its growth. Arcadia is the site of the Arboretum of Los Angeles County and the Santa Anita Race Track. Inc. 1903. Pop. (2000) 53,054.

arcádia, any of the 18th-century Portuguese literary societies that attempted to revive poetry in that country by urging a return to classicism. They were modeled after the Academy of Arcadia, which had been established in Rome in 1690 as an arbiter of Italian literary taste.

In 1756 António Dinis da Cruz e Silva and others established the Arcádia Lusitana, its first aim being the uprooting of Gongorism, a style studded with Baroque conceits and Spanish influence in general. Cruz e Silva's mock-heroic poem *O Hissope* (1768), inspired by the French poet Nicolas Boileau's mock epic *Le Lutrin* (1674), was a telling satirical document. Pedro António Correia Garção, the most prominent Arcadian, was an accomplished devotee of the Latin classical poet Horace. The bucolic verse of Dómingos dos Reis Quita signified a return to the native tradition of two centuries earlier. Sincerity and suffering spoke in the better-known *Marília de Dirceu*, pastoral love lyrics written by Tomás António Gonzaga under the pseudonym Dirceu and published in three volumes (1792, 1799, 1812).

In 1790 a Nova Arcádia ("New Arcadia") came into being, its two most distinguished members being the rival poets Manuel Maria Barbosa du Bocage, who is now remembered for a few outstanding sonnets, and José Agostinho de Macedo, known for his experiments with the epic form. Curvo Semedo was another New Arcadian of merit.

Cruz e Silva was sent to Brazil as a judge in 1776; there he helped stimulate Brazilian interest in the Arcadian movement, which gave rise to the so-called Minas school of epic and Neoclassical poets, which includes José Basílio da Gama and José de Santa Rita Durão.

Arcadia, Academy of, Italian ACCADEMIA DELL'ARCADIA, Italian literary academy founded in Rome in 1690 to combat Marinism, the dominant Italian poetic style of the 17th century. The Arcadians sought a more natural, simple poetic style based on the classics and particularly on Greek and Roman pastoral poetry.

The Academy of Arcadia was inspired by Queen Christina of Sweden, who, having given up her throne, gathered a literary circle in Rome. After Christina's death in 1689, her friends founded the academy to give their meetings permanence and "to exterminate bad taste, and to see to it that it shall not rise again." They named the academy for Arcadia, a pastoral region of ancient Greece, and assumed Greek names themselves.

Among the founding members of the Academy of Arcadia were the classicist and critic Gian Vincenzo Gravina, Giovan Mario

Crescimbeni, Giovan Battista Zappi, Alessandro Guidi, and Carlo Innocenzo Frugoni. Although most Arcadian poetry was rather pale and imitative, the academy had two outstanding writers in the 17th and 18th centuries: Paolo Rolli, who was particularly skilled in *canzonetti*, and Pietro Metastasio, one of the greatest lyricists and librettists in Italian literature. Gabriello Chiabrera, who experimented with metrical forms, was also an Arcadian, as were Gabriele Rossetti (the father of the English poets Dante Gabriel and Christina Rossetti) and Pope Leo XIII, an accomplished poet who wrote a poem for the academy's 200th anniversary.

The Academy of Arcadia was an important influence in achieving a simplification of Italian poetry. It also inspired the establishment in Italy of many Arcadian colonies that sought a return to a pastoral existence rather than having a specifically literary purpose. The 18th-century reformer of Italian comedy, Carlo Goldoni, was a member of one such colony at Pisa before he began his career.

In 1925 the academy was made an academic and historical institute and was renamed the Italian Literary Academy (Accademia Letteraria Italiana).

Arcadius (c. 377–408), Eastern Roman emperor conjointly with his father, Theodosius I, from 383 to 395, then solely till 402, when he associated his son Theodosius II with his own rule. Frail and ineffectual, he was dominated by his ministers, Rufinus, Eutropius, and Anthemius. His empire was a prey to the Goths, and his consort Eudoxia abetted the persecution of the patriarch St. John Chrysostom.

Arcaro, Eddie, byname of GEORGE EDWARD ARCARO (b. Feb. 19, 1916, Cincinnati, Ohio, U.S.—d. Nov. 14, 1997, Miami, Fla.), American jockey who was the first to ride five Kentucky Derby winners and two U.S. Triple Crown champions (winners of the Kentucky Derby, the Preakness Stakes, and the Belmont Stakes). In 31 years of riding Thoroughbreds (1931–61), he won 549 stakes events, a total of 4,779 races, and more than \$30,000,000 in purses. On Feb. 20, 1958, at Santa Anita Race Track in California, he became the third jockey (after Sir Gordon Richards and Johnny Longden) to achieve 4,000 victories.

Arcaro won the Kentucky Derby five times (1938, 1941, 1945, 1948, 1952), the Preakness six times (1941, 1948, 1950–51, 1954, 1956), and the Belmont six times (1941–42, 1945, 1948, 1952, 1955). He rode Whirlaway to Triple Crown honours in 1941, and Citation in 1948. He established a record of \$645,145 earned by one horse (Citation) in a single season. In 1960–61, at the end of his career, Arcaro teamed with the horse Kelso to win several major stakes. After his retirement, he became a television sports commentator.

Arcellinida, protozoan order, formerly called Testacida, the members of which are commonly known as testaceans. *See* testacean.

Arcesilaus (b. 316/315 BC, Pitane, Aeolis [now in Turkey]—d. c. 241), philosopher who succeeded Crates as head of the Greek Academy; he introduced a skepticism derived either from Socrates or from Pyrrhon and Timon. Refusing to accept or deny the possibility of certainty in knowing, Arcesilaus advocated a skeptical "suspension of judgment" (*epochē*). The stoics (who held a theory of "irresistible impressions") attacked him for thus paralyzing man and vitiating the goal of philosophy, which they believed was to make man happy and vigorous. Arcesilaus replied that a wise man need know only that his actions are "reasonable" (*eulogon*).

arch, in architecture and civil engineering, a curved member used to span an opening and to support loads from above. The arch formed the basis for the evolution of the vault.

Arch construction depends essentially on the wedge. If a series of wedge-shaped blocks—*i.e.*, ones in which the upper edge is wider than the lower edge—are set flank to flank in the manner shown in the Figure, the result is an arch. These blocks are called *voussoirs*. Each *voussoir* must be precisely cut so that it presses firmly against the surface of neighbouring blocks and conducts loads uniformly. The central *voussoir* is called the keystone. The point from which the arch rises from its vertical supports is known as the spring, or springing line. During construction of an arch, the *voussoirs* require support from below until the keystone has been set in place;

Parts of a circular arch
Encyclopædia Britannica, Inc.

this support usually takes the form of temporary wooden centring. The curve in an arch may be semicircular, segmental (consisting of less than one-half of a circle), or pointed (two intersecting arcs of a circle), and noncircular curves can also be used successfully.

In masonry construction, arches have several great advantages over horizontal beams, or lintels. They can span much wider openings, and this can be achieved using small, easily carried blocks of brick or stone rather than by a massive, monolithic stone lintel. An arch can also carry a much greater load than a horizontal beam can. This carrying capacity stems from the fact that pressure downward on an arch has the effect of forcing the *voussoirs* together instead of apart. These stresses also tend to squeeze the blocks outward radially, however, and loads divert these outward forces downward to exert a diagonal force, called thrust, that will cause the arch to collapse if it is not properly buttressed. Hence, the vertical supports, or posts, upon which an arch rests must be massive enough to buttress the thrust and conduct it into the foundation (as in Roman triumphal arches). Arches may rest on light supports, however, where they occur in a row, because the thrust of one arch counteracts the thrust of its neighbours, and the system remains stable as long as the arches at either end of the row are buttressed. This system is put to use in such structures as arched stone bridges and ancient Roman aqueducts.

Arches were known in ancient Egypt and Greece but were considered unsuitable for monumental architecture and were little exploited. The Romans, by contrast, used the semicircular arch in bridges, aqueducts, and large-scale architecture. In most cases they did not use mortar, relying simply on the precision of their stone dressing. The Arabs popularized the pointed arch, and it was in their mosques that this form first acquired its religious connotations. Medieval Europe made great use of the pointed arch, which constituted a basic element in Gothic architecture. In the late Middle Ages the segmental arch was intro-

duced. This form and the elliptical arch had great value in bridge engineering because they permitted mutual support by a row of arches, carrying the lateral thrust to the abutments at either end of the bridge.

Modern arches of steel, concrete, or laminated wood are highly rigid and light in weight, so that the horizontal thrust against the supports is small; this thrust can be further reduced by stretching a tie between the ends of the arch.

archaeobacterium, also spelled ARCHAEOBACTERIUM, plural ARCHAEOBACTERIA, or ARCHAEOBACTERIA, any member of a group of bacteria that differ in certain morphological, physiological, and genetic features from the eubacteria. Archaeobacteria do have some features in common with the eubacteria, however, suggesting to some researchers that the two groups shared a common ancestor early in their evolutionary history.

The archaeobacteria are aquatic or terrestrial microorganisms that exhibit a diversity of shapes, including spherical, rod-shaped, and spiral forms. Archaeobacteria lack murein (ester lipids) in the cell walls, which is characteristic of eubacteria; instead, they have ether lipids, as well as a number of different cell-wall constituents. Archaeobacteria also differ from eubacteria in the structure of their ribosomal RNAs, which are used in genetic testing to assess the degree of genetic relatedness among different species. The archaeobacteria reproduce using a wide variety of mechanisms, including binary and multiple fission, budding, and fragmentation.

Archaeobacteria survive in a number of extreme environments, including very hot or saline ones. Archaeobacteria may be aerobic, anaerobic, or facultatively anaerobic in their metabolic requirements. Some archaeobacteria, such as *Halobacterium*, require a highly saline environment. Others, such as *Methanobacterium*, produce methane (CH₄) as an end product, while still others are dependent on sulfur for their metabolism. The latter group are among the most thermophilic of the archaeobacteria, surviving in temperatures higher than 45° to 50° C (113° to 122° F).

archaeocyathid, any member of an extinct group of marine organisms of uncertain relationships found as fossils in marine limestones of Late Precambrian and Early Cambrian age (the Precambrian Period ended 540 million years ago and was followed by the Cambrian). Some authorities place them in their own phylum, Archaeocyatha; others place them in phylum Porifera. The archaeocyathid fossils represent the calcareous supporting structure built by what is presumed to be an animal, but of the creature itself little is known.

Archaeocyathid structures are conical or tubular in shape and superficially resemble horn corals. The archaeocyathid skeleton consists of thin inner and outer walls, supported by vertical partitions. The entire structure is porous. It is thought that the archaeocyathids most closely resemble the calcareous sponges. The archaeocyathids probably fed much as sponges do—by drawing in water and separating food material from it before discharging the strained water. Archaeocyathids lived upon the sea bottom in shallow water and formed large, reeflike masses. Archaeocyathid reefs have a worldwide distribution and have been found in Australia (in much the same region currently occupied by the Great Barrier Reef), Antarctica, Spain, Sardinia, Siberia, Newfoundland, Quebec, Labrador, New York, and California. It is possible that archaeocyathids filled much the same role as the later true corals and, like them, inhabited warm, shallow marine environments.

archaeological timescale, the chronological subdivisions of human prehistory, first developed by the Danish archaeologist C.J. Thom-

sen (1788–1865) as the Stone Age, Bronze Age, and Iron Age (*qq.v.*). The early portion of this scale has since been refined into more complex subdivisions. See Paleolithic Period; Mesolithic Period; Neolithic Period.

archaeology, also spelled ARCHEOLOGY, the scientific study of the material remains of past human life and activities. These include human artifacts from the very earliest bones and stone tools to the man-made objects that are buried or thrown away in the present day. Archaeological investigations are a principal source of knowledge of prehistoric, ancient, and extinct cultures.

A brief treatment of archaeology follows. For full treatment, see MACROPAEDIA: History, Study of.

For a description of the place of archaeology in the circle of learning, see PROPAEDIA: Part Ten, Division IV.

The materials that are archaeology's subject of research and study include everything made or used by human beings: tools, utensils, weapons, ornaments, buildings, settlements, monuments, and inscriptions. (A general term for any one of the things made by a human being is artifact.) The archaeologist's first task is to describe, classify, and analyze such artifacts, but his main task is to place these material remains in historical contexts, to supplement what may be known from written sources, and thus to increase the general understanding of the human past. Strictly speaking, archaeology is not concerned with the analysis and interpretation of the bones of ancient humans themselves—whether fossilized or not. The study of these is the concern of the physical anthropologist or human paleontologist. Neither is the archaeologist normally prepared to decipher or interpret the writings of ancient peoples—this is the specialty of the epigraphist and philologist.

The principal activities of the archaeologist include preliminary fieldwork—*i.e.*, the discovery and recording of sites—and the excavation, classification, dating, and interpretation of materials. Most important excavations are conducted only after careful planning, though many important sites have been discovered and excavated in the course of preparations for construction projects. All forms of excavation require great skill, extreme care in the actual uncovering of buried artifacts, and the meticulous recording of what is found by means of words and pictures.

The analysis of artifacts entails the precise description and classification of those objects by form and use, determination of the materials from which they were made, placing of the objects in environmental and cultural contexts, relative or absolute dating, and historical interpretation. For many years, dating was based on historical records (in the case of Classical archaeology), stratigraphy (the study of the relative chronology of the Earth's strata), and dendrochronology (analysis of tree rings). In 1948, however, the development of radioactive-carbon dating permitted absolute dating of materials up to 40,000 years old; subsequent techniques have extended this timescale considerably further.

Archaeopteris, fossil genus of plants originally—and sometimes still—considered early tree ferns in the order Protopteridales but now generally and tentatively assigned to a transitional fern group ancestral to both seed ferns and conifers. It was common in the Late Devonian Epoch (374 to 360 million years ago).

Callixylon, a genus reserved for fossil stem fragments of a plant in the order Cordaitales, is now also known to contain many stem fragments associated closely with the fronds of *Archaeopteris* and is judged to belong to that genus.

Archaeopteryx, the oldest known fossil animal that is generally accepted as a bird. It flourished during the Late Jurassic Period (the Late Jurassic occurred from 163 to 144 mil-

Archaeopteryx skeleton, cast made from a fossil found in matrix

By courtesy of the American Museum of Natural History, New York

lion years ago). The known fossil specimens were found in the Solenhofen Limestone Formation in Bavaria, a very fine-grained Jurassic limestone formed in a shallow, tropical marine environment, probably in a coral lagoon, where lime-rich muds slowly accumulated and permitted fossil material to be exceptionally well preserved. Several of the fossil skeletons have clear impressions of feathers.

The sizes of the specimens range from that of a blue jay to that of a large chicken. *Archaeopteryx* shared many anatomical characters with theropods (*q.v.*; small bipedal dinosaurs). The skull, like those of birds, possessed an expanded braincase, large eye sockets, and a pronounced beak. Unlike modern birds, however, *Archaeopteryx* had well-developed teeth. The head was balanced upon a long, thin, and probably very flexible neck. The spinal column was simple in character. A long, well-developed tail was present, similar in structure to that of the smaller dinosaurs, but it had feathers in a row on either side. The hind legs possessed three claws at their extremities and were birdlike.

Archaeopteryx had well-developed wings, and the structure and arrangement of its wing feathers—similar to what is found in modern birds—indicate that it could fly. Skeletal structures related to flight are incompletely developed, however, suggesting that *Archaeopteryx* may have been an awkward flier. Although *Archaeopteryx* is almost universally accepted as a bird, some experts consider it to have been a feathered dinosaur because of its theropod-like skeletal anatomy.

Archaic culture, any of the ancient woodlands cultures of North America, in what is now the northeastern United States, dating from about 8000 BC to 1000 BC.

Variants of these cultures persisted considerably later to the west and to the north. The people subsisted on small-game hunting, fishing, and collecting and characteristically made such tools as large, broad, chipped-stone projectile points, milling and grinding stones, and bone implements and ornaments; by about 5000 BC they had developed such ground and polished stone objects as axes, spear-thrower weights, and bowls. From the 5th to the 2nd millennium BC, there appeared a related Old Copper culture in the upper Great Lakes region, which used copper for tools and weapons.

Archaic period, in history and archaeology, the earliest phases of a culture; the term is most frequently used by art historians to denote the period of artistic development in Greece from about 650 to 480 BC, the date of the Persian sack of Athens.

During the Archaic period, Greek art became less rigidly stylized and more naturalistic. Paintings on vases evolved from geometric designs to representations of human figures, often illustrating epic tales. In sculpture, faces were animated with the characteristic "Archaic smile," and bodies were rendered with a growing attention to human proportion and anatomy. The development of the Doric and Ionic orders of architecture in the Archaic period also reflected a growing concern with harmonious architectural proportions.

Archaic smile, the smile that characteristically appears on the faces of Greek statues of the Archaic period (c. 650–480 BC), especially those from the second quarter of the 6th century BC.

The significance of the convention is not known, although it is often assumed that for the Greeks this kind of smile reflected a state of ideal health and well-being. It has also been suggested that it is simply the result of a

Archaic smile, detail of a kouros (statue of a young man) from Tenea, Greece, c. 575–550 BC; in the Antikensammlung, Munich

technical difficulty in fitting the curved shape of the mouth to the somewhat blocklike head typical of Archaic sculpture.

archangel, any of several chiefs, rulers, or princes of angels in the hierarchy of angels of the major Western religions, especially Judaism, Christianity, and Islām, and of certain syncretic religions, such as Gnosticism. *See* angel.

Archangel (city, Russia): *see* Arkhangelsk.

archbishop, in the Christian church, a bishop who, in addition to his ordinary episcopal authority in his own diocese, usually has jurisdiction (but no superiority of order) over the other bishops of a province. The functions of an archbishop developed out of those of the metropolitan, a bishop presiding over a number of dioceses in a province, though the title of archbishop, when it first appeared, implied no metropolitan jurisdiction. It seems to have been introduced in the Eastern church in the 4th century as an honorary title of certain bishops. In the Western church it was little known before the 7th century, and it did not become common until the Carolingian emperors revived the right of metropolitans to summon provincial synods. The metropolitans then commonly assumed the title of archbishop to mark their preeminence over the other bishops. The Council of Trent (1545–63) reduced the powers of the archbishop, which had been quite extensive in the European Middle Ages. In the modern Roman Catholic church the title is also used occasionally as an honorary title for certain bishops who are not metropolitans.

In the Orthodox and other churches of the East, the title of archbishop is far more common than in the West, and it is less consistently associated with metropolitan functions. In the Orthodox church there are autocephalous

archbishops who rank between bishops and metropolitans.

In the Protestant churches of continental Europe, the title of archbishop is rarely used. It has been retained by the Lutheran bishop of Uppsala, who is metropolitan of Sweden, and by the Lutheran bishop of Turku in Finland.

In the Church of England the ecclesiastical government is divided between two archbishops: the archbishop of Canterbury, who is called the "primate of all England" and metropolitan of the province of Canterbury, and the archbishop of York, who is called the "primate of England" and metropolitan of York. *See also* metropolitan.

archdeacon, in the Christian church, originally the chief deacon at the bishop's church; during the European Middle Ages, a chief official of the diocese; an honorary title in the modern Roman Catholic church. The name was first used in the 4th century, although a similar office existed in the very early church. Appointed by the bishop, the archdeacon was charged with the duties of preaching, supervising the deacons and their work, and supervising the distribution of alms. Eventually he became the first assistant to the bishop in the administrative and disciplinary work of the diocese and even represented the bishop at councils. When the bishop died, the archdeacon governed the diocese until a successor was elected.

From the 10th to the 13th century the archdeacon (usually an ordained priest) became more powerful. He was given jurisdiction over a defined territory, and dioceses were divided into several archdeaconries. The office was conferred irrevocably by the cathedral chapter rather than by the bishop. Thus, archdeacons became rivals of the bishop and exercised in their territories all the rights of a bishop except the power of ordaining.

During the 13th century a reaction began by the bishops, and the power and authority of archdeacons declined rapidly during the 14th and 15th centuries. The Council of Trent took away most of their powers.

The office developed similarly in the Eastern church and is today primarily an honorary title.

In the Anglican church, archdeacons have administrative authority, delegated by a bishop, over an entire diocese or part of one. Their duties vary.

archduke, feminine ARCHDUCHESS, a title, proper in modern times for members of the house of Habsburg. The title of archduke Palatine (*Pfalz-Erzherzog*) was first assumed by Rudolf IV, Duke of Austria, on the strength of a forged privilege, in the hope of gaining for the dukes of Austria an equal status with the electors of the Holy Roman Empire. The emperor Charles IV refused to recognize the title, and it was not juridically held by the Habsburgs until 1453, when the emperor Frederick III, a Habsburg, confirmed Rudolf's privilege

and granted the title of archduke of Austria to his son Maximilian and his heirs. All males of the house of Habsburg bore this title; their daughters and wives were archduchesses. The title of archduke or archduchess of Austria also occurred in the royal style of the Bourbon kings and queens of Spain, though they were not descended in the male line from their Habsburg predecessors.

arche-, archeo- (combining form): *see under* *archae-, archaeo-*.

Archean eon, also spelled *ARCHAEAN*, also called *ARCHEOZOIC*, the earlier of the two divisions of the Precambrian time (3.8 billion to 570 million years ago). The Archean eon began with the formation of the Earth's crust about 3.8 billion years ago and extended to about 2.5 billion years ago, up to the start of the Proterozoic eon; the latter is the second and younger division of the Precambrian period. The earliest and most primitive forms of life—bacteria and blue-green algae—originated about 3.5 billion years ago in the middle of the Archean eon. (The Archean's alternative name, *Archeozoic*, means "ancient life.") Metamorphosed igneous Archean-eon rocks are found on all the continents.

arched harp, musical instrument in which the neck extends from and forms a bow-shaped curve with the body. One of the principal forms of harp, it is apparently also the most ancient: depictions of arched harps survive from Sumer and Egypt from about 3000 BC. Both areas had harps played in vertical position, plucked with the fingers of both hands, often by a kneeling musician. Sumer also had horizontal arched harps—*i.e.*, laid across the lap, strings toward the player, and sounded by a plectrum swept across the strings, the left-

Uganda musician playing the *ennanga* arched harp

Gerhard Kubik

hand fingers damping unneeded strings. The arched harp disappeared from Sumer and subsequent Mesopotamian civilizations but continued in use in Egypt.

From ancient civilizations the arched harp apparently diffused southward in Africa, where it is still played (*e.g.*, the *ennanga* of Uganda), and eastward across India to Southeast Asia, where it survives as the Burmese harp, *saung gauk*. Modern African harps often have cloth rings on the neck that produce a buzzing tone colour as the strings vibrate against them.

Arched harps were prominent in ancient Central Asia, and 1st-century frescoes (Gandhāra culture, in modern Pakistan) show a seemingly archaic variety that survives almost unchanged in the *vaji*, or Kafir harp, of Nūrestān in Afghanistan. This instrument's neck pierces and then emerges from the skin belly; the strings run from the neck to the protruding end (in most harps they pass through the belly).

archegonium, the female reproductive organ in ferns and mosses. An archegonium also occurs in some gymnosperms, *e.g.*, cycads and conifers. A flask-shaped structure, it consists of a neck, with one or more layers of cells, and a swollen base—the venter—which contains the egg. Neck-canal cells, located above the egg, disappear as the archegonium matures, thus producing a passage for entry of the sperm. The sperm are produced in the corresponding male reproductive organ, the antheridium.

Archelaus (d. 399 BC), king of Macedonia from 413 to 399.

Although he acceded to power illegally, Archelaus was a capable and beneficent ruler. His father was King Perdiccas II (reigned c. 450–413) and his mother a slave. Archelaus seized the throne after murdering his uncle, his cousin, and his half brother, the legitimate heir. He then set about strengthening Macedonia by fortifying cities, constructing roads, and reorganizing the army. In an effort to spread the refinements of Greek civilization among his people, Archelaus invited many renowned artists, among them the tragedian Euripides, to his new capital at Pella. The king also celebrated Greek-style games at Dium, in Macedonia. During Archelaus' reign the Macedonian economy was strengthened through the development of trade and adoption of the Persian coin standard. His relations with other states were generally peaceful. In 420 he helped establish a pro-Macedonian oligarchy at Larissa in Thessaly. He was assassinated by one of his favourites while hunting.

Archelaus, in full *ARCHELAUS SISINES* (d. AD 17), last king of Cappadocia (reigned 36 BC–c. AD 14), a Roman client during the late republic and the early empire.

Although granted the kingdom by Mark Antony, Archelaus retained his crown by making peace with Octavian (later Augustus) after Antony's defeat at the Battle of Actium (31 BC). In 20 BC Cilicia Trachea, eastern Lycaonia, and Armenia Minor were added to his domain, and his marriage to King Polemo's widow gave him indirect control of most of Pontus. When Tiberius succeeded Augustus (AD 14), Archelaus was summoned to Rome, accused in the Senate, and soon deprived of his throne. He died soon after. In AD 17 Cappadocia was made a Roman province.

Archelon, extinct giant sea turtle known from fossilized remains found in North American rocks of the Late Cretaceous epoch (97.5 million to 66.4 million years ago). *Archelon*, protected by its formidable bony armour, reached a length of about 3.5 m (12 feet). The front feet developed into powerful structures that could efficiently propel the great bulk of *Archelon* through the water.

archeology: *see* *archaeology*.

Archer, Frederick Scott (b. 1813, Bishop's Stortford, Hertfordshire, Eng.—d. May 2, 1857, London), English inventor of the first practical photographic process by which more than one copy of a picture could be made.

Archer, a butcher's son, began his professional career as an apprentice silversmith in London, then turned to portrait sculpture. To assist him in this work, he began experimenting with the calotype photographic process of William Henry Fox Talbot. In 1851 he described his wet collodion process, by which finely detailed glass negatives were produced; from these, paper positives could be printed. The plates had to be developed before the sensitized collodion dried after exposure, so that a darkroom tent and portable laboratory were needed for outdoor photography; but the new process produced such good results that it dominated photography for a generation. A lawsuit by Talbot claiming that the wet collodion was merely a variant of his own process was dismissed.

Archer also invented the ambrotype, a cheap form of portraiture, in collaboration with another photographer, but, having devoted all his funds to research, he died in poverty.

Archer, Thomas (b. c. 1668—d. May 23, 1743, London), architect and practitioner of what was, for England, an extraordinarily extravagant Baroque style, marked by lavish curves, large scale, and bold detail.

Archer, the son of a Warwickshire squire, was educated at Trinity College, Oxford, and then spent four years abroad. The recipient of

The Church of St. John, Smith Square, Westminster, London, by Thomas Archer, 1714

A F Kersting

some lucrative royal appointments, he bought the manor of Hale, Hampshire, in 1715 and rebuilt the house and church.

Archer's dynamic work borrowed much from the 17th-century Italian architects Gian Lorenzo Bernini and Francesco Borromini. Although he was not as original as some of the prominent English architects of his time, he was considered an important architect. Most of his designs were executed from 1705 to 1715, including the north front of Chatsworth House, Derbyshire (1705); Heythorpe Hall, Oxfordshire (c. 1705); a garden pavilion at Wrest Park, Bedfordshire (1711); Roehampton House, Surrey (1712); and the churches of St. Philip, Birmingham (1710), St. Paul, Deptford (1712), and St. John, Westminster (1714). The last two resulted from his appointment in 1711 as a commissioner for the building of 50 new churches.

Archer, William (b. Sept. 23, 1856, Perth, Perth, Scot.—d. Dec. 27, 1924, London), drama critic whose translations introduced Henrik Ibsen to the British public.

While studying law at Edinburgh, Archer began his journalistic career on the *Edinburgh Evening News*. After a world tour (1876–77), in 1878 he moved to London and in 1879 became drama critic on the *London Figaro*. In 1884 he joined the *World*; his reviews for it and other periodicals were collected in *The Theatrical "World,"* 5 vol. (1893–97). He was later drama critic on the *Nation*, the *Tribune*, and the *Manchester Guardian*.

The translations of Ibsen that were to make him famous began with *Pillars of Society* (1880), the first of the plays produced in England. Later translations included *A Doll's House* (1889), *Ibsen's Prose Dramas*, 5 vol. (1890–91), *Peer Gynt* (1892), *The Master Builder* (1893), and the *Collected Works*, 12 vol. (1906–12). Despite faults, these had great influence and remain popular. His support for a national theatre prompted *A National*

Theatre: Scheme and Estimates (1907), with Harley Granville-Barker. Of his plays, four were posthumously published; *The Green Goddess* (New York, 1921; London, 1923) was extremely successful and often revived.

archer fish, any of five species of Indo-Pacific fishes of the family Toxotidae (order Perciformes) noted for their ability to knock their insect prey off overhanging vegetation by "shooting" it with drops of water expelled from their mouths. The insect falls into the water, where it can be eaten by the fish. Archer fishes are elongated, with relatively deep bodies that are almost flat from the dorsal fin forward. The head is pointed, the mouth is large, and the dorsal and anal fins are placed toward the back of the body. Different species are spotted or vertically banded with black.

Archer fish (*Toxotes jaculator*) "shooting" at prey
Roy Pinney

Archer fishes live in both freshwater and saltwater, usually remaining near the surface. One of the best-known species is *Toxotes jaculator* (or *T. jaculatrix*), which grows about 18 cm (7 inches) long.

archery, sport involving shooting arrows with a bow, either at an inanimate target or in hunting.

History. From prehistoric times, the bow was a principal weapon of war and of the hunt throughout the world, except in Australia. Recreational archery also was practiced, along with military, among the ancient Egyptians and Greeks, one instance of the latter being the competition in which Odysseus won the hand of Penelope. The Huns, Seljuq Turks, Mongols, and other nomadic horse archers dominated large parts of Asia for about 15 centuries from the 1st century AD. English longbowmen achieved glorious military victories in the Hundred Years' War (1357-1453), while on continental Europe the crossbow (*q.v.*) became widely used, especially in Switzerland, parts of Germany, France, and the Low Countries. In Europe the bow and arrow were displaced by firearms as a military weapon in the 16th century. By the time the Spanish Armada attempted to invade England in 1588, an English county troop levy consisted of one-third bowmen to two-thirds soldiers with guns, and by century's end the bow had been almost abandoned as a weapon.

The bow was retained as a hunting weapon, and archery continued to be practiced as a sport in England by both royalty and the general public. The earliest English archery societies dated from the 16th and 17th centuries. The prince of Wales, afterward George IV, became the patron of the Toxophilite Society in 1787 and set the prince's lengths of

100 yards (91 m), 80 yards (73 m), and 60 yards (55 m); these distances are still used in the British men's championship York round (six dozen, four dozen, and two dozen arrows shot at each of the three distances). These recreational activities with the bow evolved into the modern sport of archery. In 1844 the first of the Grand National Archery Meetings—the British championships—was held at York, and the Grand National Archery Society became the governing body of the sport in the United Kingdom. International rules were standardized in 1931 with the founding of the Fédération Internationale de Tir à l'Arc (FITA; Federation of International Target Archery) in Paris.

The first American archery organization was the United Bowmen of Philadelphia, founded in 1828. In the early days the sport was, as in England, a popular upper- and middle-class recreation. In the 1870s many archery clubs sprang up, and in 1879 eight of them formed the National Archery Association of the United States. In 1939 the National Field Archery Association of the United States was established to promote hunting, roving, and field archery. The number of archers around the world increased phenomenally after 1930, led by remarkable growth in the United States. By the late 20th century there were probably more than 10 million American participants in all forms of the sport. Their ranks included those who use the bow to hunt game; those who engage in shooting at targets of several kinds at various distances for accuracy; and those who strive for ever-greater distances in "flight" shooting.

The bow. The bow was almost certainly the earliest mechanical device to achieve greater speed in a projectile than could be attained by throwing it. It does this by accumulating energy in the bow limbs while drawing (pulling the bowstring back), storing it temporarily while holding and aiming, and releasing the stored energy by converting it to energy of flight in the arrow. Initially, and probably for millennia, bows were made of a single material, usually wood (self bows), including those in which two pieces were fastened together to make the equivalent of a single long stave. Later, some bows were made of several materials, such as wood and horn glued together in layers (composite bows) and reinforced with bands of sinew. The short self bows used in Europe until the late Middle Ages were weak weapons that gave way to the technically superior longbow (*q.v.*) beginning in the 11th century. The English longbow, made of wood from the English yew tree (*Taxus baccata*), became famous in legend and history for the victories it won over the French at the battles of Crecy, Poitiers, and Agincourt during the Hundred Years' War. Composite bows made of wood, horn, and sinew were used throughout much of Asia during the same period.

Up to about 1930 the history of Western archery as a sport was the history of the longbow. This bow had disadvantages, however. It was subject to differing conditions of temperature and humidity, it needed to be left unstrung when not in use, and using it was an art. The bow that replaced it in the mid-20th century was a composite design made of laminated wood, plastic, and fiberglass that was little affected by changes of temperature and humidity. The limbs of the composite bow are laminated, with a thin strip of wood serving as a core for facing and backing strips of fiberglass that are secured to it with epoxy glue. The bow's rigid middle section gives the archer a good grip, and its thin, wide, fiberglass limbs are exceedingly strong. The composite bow gives superior accuracy, velocity, and distance in comparison to the longbow. Using a modern bow, target archers of equal skill can score an average 30 to 40 percent higher than they can with the longbow. The modern composite bow shoots farther than the longbow:

Front and side views of (top) longbow and (bottom) modern composite bow relaxed, braced, and fully drawn

a maximum distance of more than 850 yards has been obtained with it, compared to about 300 yards for the longbow. The efficiency (the percentage of energy in a fully drawn bow that is transferred to the arrow at the moment of loose) of the modern bow doubles that of the longbow, the velocity of the arrow with the new bow reaching 212 feet (65 m) per second as opposed to 150 feet per second. The wooden arrows used by archers for millennia have been replaced by ones made from aluminum-alloy or fiberglass tubing, and plastic fins have replaced feathers. The arrows' points are made of steel, and nylon is used for the bowstring. For a comparison of the design of the longbow and the modern composite bow, see the Figure.

A more recent innovation is the compound bow, which uses a system of cables and pulleys to make the bow easier to draw. Compound bows have achieved increasing popularity since a two-pulley design was introduced in the 1960s. They are used in field archery, in hunting, and in international target archery competition. See also bow and arrow.

Equipment. The modern target bow varies in length according to the height of the archer but is usually 68 to 70 inches. Similarly, arrows vary from 22 to 30 inches. The drawing force of a bow (the number of pounds of energy needed to draw back an arrow to the fullest) varies from 30 to 50 pounds (14 to 23 kg) for men and from 20 to 40 pounds for women. The archer usually carries arrows in a quiver, a container hung over the shoulder or slung from the belt. A glove or finger protector shields the fingers used to draw the bowstring back, and a bracer is fitted to the inside forearm of the bow arm to protect against the released bowstring. In Western nations, the so-called Mediterranean draw is used to draw and loose the arrow; this is executed by pulling the string back with three fingers, the first being above and the second and third below the nocked arrow. With right-handed shooting, the arrow is shot from the left side of the bow.

A target is usually a boss of tightly coiled straw rope about 4 inches thick and about 4

feet in diameter on which is stretched a canvas face with concentric scoring rings (British, 5 rings; FITA, 10), scored 9, 7, 5, 1 outward from the centre (British; also used in the United States) and 10 through 1 (FITA). Target sizes vary at different distances.

Additional pieces of equipment have become common with the increasing popularity of the sport. These include devices attached to the bow, such as stabilizers (long rods that project from the bow), torque flight compensators (shorter rods with weights attached), counterweight rods, and lens-less bowsights (devices used for aiming). When these devices are allowed, competition is called freestyle; when they are not, it is known as bare bow.

Competition. The main forms of competitive archery are field archery and target archery. In field archery (*q.v.*), competitors shoot arrows at different-sized targets set at varying and undetermined distances around a course. In target archery, competitors shoot a specified number of arrows at set distances at a target with established scoring values. A round is a target-shooting competitive event in which a specified number of arrows are shot at a specified distance, and scoring is done after the round or rounds. Principal kinds of rounds include the American round, Hereford round, National round, and York round. FITA round distances are 90, 70, 50, and 30 m (295, 230, 164, and 98 feet) for men and 70, 60, 50, and 30 m for women, and the former standard FITA round for both men and women consisted of 36 arrows per round being shot at each distance. Since the 1930s the FITA specifications have been those most widely used. (See also FITA round.)

Archery events for men were held in the Olympic Games in 1900, 1904, 1908, and 1920 and for women in 1904 and 1908. They were then suspended until the 1972 Games, when they were reintroduced for both men and women and continued thereafter. World championship matches have been held on either an annual or biennial basis from 1931 (except during World War II), when FITA, the international governing body of the sport, was organized. FITA events (including Olympic Games from 1972) are shot at metric distances, and from 1957 to 1985 in double FITA rounds. In 1985, to improve archery as a spectator sport, a new championship round known as the grand FITA round, with single-elimination matches, was adopted. The grand FITA round first appeared in the Olympic Games in 1988, when team competition was introduced to the program. The 1992 Olympic Games saw the debut of the FITA Olympic round, a championship round of single-elimination, head-to-head matches.

Other forms of sport archery. Clout shooting (*q.v.*) originated at least as early as the late 16th century and is mainly British. Flight shooting (*q.v.*) was practiced in England at the end of the 16th century and was also popular in Turkey with a composite bow.

For world championships in target archery, both individual and team, see *Sporting Record: Archery*. See also *Olympic Games*.

(P.E.K./Ed.)

Arches National Park, a desert area of rock pinnacles, windows, and arches in eastern Utah, U.S., on the Colorado River, just north of Moab. It was established as a national monument in 1929 and as a national park in 1971 and is 115 square miles (298 square km) in area. The area's red limestone has been eroded into unusual shapes, including Courthouse Towers (with spires that resemble skyscrapers), The Windows Section, Delicate Arch, Fiery Furnace (so named because it glows in the setting sun), and Devils Garden (the site of Landscape Arch, at 291 feet [89 m] the longest natural rock bridge in the world).

archetype (from Greek *archetypos*, "original pattern"), in literary criticism, a primordial

image, character, or pattern of circumstances that recurs throughout literature and thought consistently enough to be considered a universal concept or situation. The term was adopted by literary critics from the writings of the psychologist Carl Jung, who formulated a theory of a "collective unconscious." For Jung, the varieties of human experience have somehow been genetically coded and transferred to successive generations. These primordial image patterns and situations evoke startlingly similar feelings in both reader and author.

Archidamus, also spelled ARCHIDAMOS, name of five kings of Sparta, of the Eurypontid house, grouped below chronologically and indicated by the symbol ●.

● **Archidamus I** (fl. 7th century BC), 12th king of Sparta of the Eurypontid line. The son of Anaxidamus, he ruled shortly after the close of the second Messenian War (c. 660 BC) and toward the outset of the long war between Sparta and Tegea (the Tegean War). His reign was described by the geographer Pausanias as quiet and peaceful.

● **Archidamus II** (d. 427 BC), king of Sparta from about 469.

A member of the Eurypontid house (one of the two royal families of Sparta), he succeeded to the throne of his grandfather, Leotychides. When the Messenian helots (serfs) revolted against their Spartan masters following a severe earthquake about 464, Archidamus organized the defense of Sparta. Nevertheless, for the next 30 years all known operations of the Spartan army were commanded by members of the other royal house (the Agiads), and there is no further record of Archidamus' activities until 432, when, according to the Greek historian Thucydides, the king attempted without success to prevent the outbreak of war with Athens (Peloponnesian War, 431–404).

Archidamus led the Spartan invasions of Attica in 431, 430, and 428 and a campaign against Plataea in 429. The first 10 years of the conflict are known as the Archidamian War. His two sons became the Spartan rulers Agis II and Agesilaus II.

● **Archidamus III** (d. 338 BC, Manduria, Calabria [Italy]), king of Sparta, 360–338, succeeding his father, Agesilaus II.

Archidamus headed the force sent to aid the Spartan army after its defeat by the Thebans at the Battle of Leuctra in 371 and was commander later during the confused fighting in the Peloponnese. He scored a victory over the Arcadians in 367 but was in turn defeated by them in 364 at Cromnus. In 362 he showed great courage in the defense of Sparta against the Theban commander Epaminondas. As king, Archidamus supported the Phocians against Thebes in the Sacred War of 355–346. Leading a mercenary army to help Tarentum (modern Tarento, Italy) against the Lucanians, he fell with most of his troops at nearby Manduria.

● **Archidamus IV** (fl. 3rd century BC), king of Sparta, son of Eudamidas I, grandson of Archidamus III. The dates of his accession and death are unknown. In 294 BC he was defeated by Demetrius I Polioretetes of Macedonia in a battle at Mantinea, and Sparta was saved only because Demetrius I was called away by the threatening activities of a rival Lysimachus and Ptolemy II.

● **Archidamus V** (fl. 3rd century BC), 27th Spartan king of the Eurypontidae, son of Eudamidas II, grandson of Archidamus IV. He fled to Messenia after the murder of his brother Agis IV in 241 BC. In 227 he was recalled by Cleomenes III, who was then reigning without a colleague, but shortly after his return Archidamus was assassinated. The historian Polybius accused Cleomenes of the murder, but Plutarch is probably right in saying that it was the work of those who had caused the

death of Agis and who feared his brother's vengeance.

archil (dye): see orchil.

Archilochus (b. 675? BC, Paros [Greece]—d. 635? BC), poet and soldier, the earliest Greek writer of elegiac and personal lyric poetry whose works have survived to any considerable extent.

Archilochus was the illegitimate son of a noble father. This would probably have made little difference to his social status had he not been spurned as a suitor by a woman named Neobule. Perhaps as a result of this rebuff Archilochus went to live in Thasos, where he seems to have become a soldier of fortune, later serving in Thrace and other places and composing his poetry as he served. It is noteworthy that, unlike the writers who came before him, Archilochus saw no glory in war. There is a tradition that Archilochus died in a battle between the Thasians and the men of Naxos.

Archilochus was the first extant Greek poet who employed the elegiac couplet and the various iambic and trochaic metres (from the dimeter to the tetrameter). The surviving fragments of his work show that he was among the most skillful handlers of the Greek language and a metrical innovator of the highest ability and importance. He was also the first European writer to make his personal experiences and feelings the main subject of his poems. The controlled yet personal voice in his verse marks a distinct departure from other surviving ancient Greek poetry, which is characteristically more formulaic and heroic. He was particularly famous for the sharp satire and ferocious invective with which he attacked Neobule and her father, not to mention other eminent Thasians and Parians. Archilochus was much admired by later poets, particularly Horace.

Archimedes (b. c. 290–280 BC, Syracuse, Sicily [now in Italy]—d. 212/211 BC, Syracuse), the most famous mathematician and inventor of ancient Greece. Archimedes is especially important for his discovery of the relation between the surface and volume of a sphere and its circumscribing cylinder. He is also known for his formulation of a hydrostatic principle (known as Archimedes' principle) and a device for raising water, known as the Archimedes screw.

A brief treatment of Archimedes follows. For full treatment, see *MACROPAEDIA: Archimedes*.

Except for a brief period early in his career in Alexandria, Egypt, Archimedes spent most of his life in the Greek city-state of Syracuse. War machines of his construction greatly delayed the capture of the city by Roman forces in 212 or 211 BC, at which time Archimedes was killed by a Roman soldier.

Archimedes won great renown for his inventions, such as the Archimedes screw and two astronomical globes, but the veracity of several anecdotes about his life is uncertain. For example, although his war machines were long successful against the Romans, it is doubtful that he constructed an array of mirrors to burn their ships.

Archimedes' theoretical work that could be simply expressed—such as the formulas for the surface area and volume of a sphere—became mathematical commonplaces, and one of the bounds that he established for pi, $\pi \approx \frac{22}{7}$, was adopted as the usual approximation into the Middle Ages. But he had little influence on the development of mathematics until the science was revived by the Arabs in the 8th or 9th century and the Europeans in the 16th and 17th centuries.

There are nine known extant treatises in

Greek by Archimedes, and the references of later authors indicate that he had written a number of other works that are now lost. Of the known works, five are of particular interest.

On the Sphere and Cylinder contains his discovery that the volume of a sphere is two-thirds that of the cylinder in which it is inscribed and that the surface area of a sphere is four times that of its greatest circle. A short work, *Measurement of the Circle*, contains his accurate and rational approximations of the value of pi and of the square roots of several numbers.

On Floating Bodies, which survives only partly in Greek, is the first known work in hydrostatics, of which Archimedes is the recognized founder. It contains the work leading to Archimedes' principle—that a solid denser than a fluid will, when immersed in that fluid, be lighter by the weight of the fluid it displaces. *The Sand-Reckoner* remedies the inadequacies of the Greek numerical notational system by creating a place-value system of notation.

Method Concerning Mechanical Theorems describes the "mechanical" technique used by Archimedes to arrive at the values proved mathematically in *On the Sphere and Cylinder*. The author's hope that this treatise would lead other mathematicians to new discoveries was unfulfilled because the work was lost until the 19th century.

Archimedes' principle, physical law of buoyancy, discovered by the ancient Greek mathematician and inventor Archimedes, stating that any body completely or partially submerged in a fluid (gas or liquid) at rest is acted upon by an upward, or buoyant, force the magnitude of which is equal to the weight of the fluid displaced by the body. The volume of displaced fluid is equivalent to the volume of an object fully immersed in a fluid or to that fraction of the volume below the surface for an object partially submerged in a liquid. The weight of the displaced portion of the fluid is equivalent to the magnitude of the buoyant force. The buoyant force on a body floating in a liquid or gas is also equivalent in magnitude to the weight of the floating object and is opposite in direction; the object neither rises nor sinks. A ship that is launched sinks into the ocean until the weight of the water it displaces is just equal to its own weight. As the ship is loaded, it sinks deeper, displacing more water, and so the magnitude of the buoyant force continuously matches the weight of the ship and its cargo.

If the weight of an object is less than that of the displaced fluid, the object rises, as in the case of a block of wood that is released beneath the surface of water or a helium-filled balloon that is let loose in air. An object heavier than the amount of the fluid it displaces, though it sinks when released, has an apparent weight loss equal to the weight of the fluid displaced. In fact, in some accurate weighings, a correction must be made in order to compensate for the buoyancy effect of the surrounding air.

Buoyancy is caused by the increase in fluid pressure at increasingly greater depths. The pressure on a submerged object, therefore, is greater on the parts more deeply submerged, and the buoyant force is always upward, or opposite to the gravitational force; it is the net effect of all the forces exerted on the object by the fluid pressure.

Archimedes screw, machine for raising water, allegedly invented by the ancient Greek scientist Archimedes for removing water from the hold of a large ship. One form consists of a circular pipe enclosing a helix and inclined at an angle of about 45 degrees to the horizontal with its lower end dipped in the water;

Archimedes screw, invention attributed to the Greek scientist Archimedes

rotation of the device causes the water to rise in the pipe. Other forms consist of a helix revolving in a fixed cylinder or a helical tube wound around a shaft.

Modern screw pumps, consisting of helices rotating in open inclined troughs, are effective for pumping sewage in wastewater treatment plants. The open troughs and the design of the screws permit the passage of debris without clogging.

archinephric duct: see Wolffian duct.

archinephros, ancestral vertebrate kidney, retained by larvae of hagfish and of some caecilians and occurring in the embryos of higher animals. Two tubes, the archinephric, or Wolffian, ducts, extend between the body cavity and the back and lead to the exterior. A series of tubules, one pair for each body segment, connects the body cavity with the Wolffian ducts. Each tubule is ciliated where it opens into the body cavity, and a knot of capillaries occurs at each of these openings, which are called nephrostomes.

The three types of adult-vertebrate kidneys develop from the embryonic archinephros: the pronephros from the anterior section, the mesonephros from the middle section, and the metanephros from the hind section.

archipallium, a portion of the pallium, in the forebrain. The pallium is the mantle, or covering, over the lateral ventricles, or cavities, of the brain. The archipallium is distinguishable as a part of the pallium in amphibians. In humans and other mammals this portion of the brain is overshadowed by the neopallium, or cerebral cortex. The part of the brain evolved from the archipallium forms the upper, inner wall of each lateral ventricle and, among other functions, serves as an olfactory centre.

archipelagic apron, layers of volcanic rock that form a fanlike slope around groups of ancient or recent islands, most commonly in the central and southern Pacific Ocean. The aprons typically have a slope of 1° to 2°, with the slope decreasing near the shore; the upper parts may be indented by deep-sea channels. Although some aprons are rough, they are more typically smooth because a veneer of sediments deposited during the last 10,000 years or so masks any volcanic relief present. Turbidity currents may play an important role in transporting debris over the aprons and enhancing their smoothness.

Archipelagic aprons occur around such island groups as the Marquesas, Marshall, Hawaiian, Samoan, and Gilbert. These aprons seem to be a topographic expression of what geophysicists term the second layer, a layer of rock that transmits seismic waves with velocities between 4 and 6 km (2.5 and 4 miles) per second; this second layer thickens near volcanic islands to form the archipelagic aprons. Formation of the thick layer seems to be caused by very fluid lava pouring out of fissures near the bases of volcanic islands.

Archipenko, Alexander (b. May 30, 1887, Kiev, Ukraine, Russian Empire—d. Feb. 25, 1964, New York, N.Y., U.S.), Ukrainian-American sculptor and painter who originated a new style in which the representation of the human figure was subordinated to the formal composition of voids and solids.

After studying in Kiev, Archipenko attended the École des Beaux-Arts in Paris (1908), where he was active in the Cubist movement. He taught art briefly in Berlin (1921–23) and for the rest of his life in New York City (1923–64), except for a short time (1937–39) when he was connected with the New Bauhaus in Chicago.

Archipenko's abstract shapes had a primitive vitality and rhythmic movement. In his "Walking Woman" (1912), holes were punched in the face and torso, and concavities substituted for the convexities of the lower legs. This opening up of the form revolutionized modern sculpture. "Boxing Match" (1913) attempted to convey the brutal energy of the sport in nonrepresentational, machinelike cubic and ovoid forms. In 1912 he executed the first collage in sculpture in his famous "Medranos," circus figures in multicoloured glass, wood, and metal, defying traditional use of materials.

Architects Collaborative, The (TAC), association of architects specializing in school buildings that was founded in 1946 in Cambridge, Mass., U.S., by Walter Gropius. The original partners included Norman Fletcher, John Harkness, Sarah Harkness, Robert McMillan, Louis McMillen, and Benjamin Thompson.

Among the works cooperatively designed through TAC teamwork were the Harvard University Graduate Center (1949–50); the U.S. Embassy in Athens (1956); the Arts and Communications Center and the Evans Science Building (both 1959) at Phillips Academy in Andover, Mass.; and the University of Baghdad (design accepted 1960). Gropius was active with TAC until his death in 1969.

architecture, the art and technique of designing and building, as distinguished from the skills associated with construction. As with some other arts, the practice of architecture embraces both aesthetic and utilitarian ends that may be distinguished but not separated, and the relative weight given to each can vary widely from work to work. Thus, at one end of the scale are purely functional structures (that may nonetheless possess certain aesthetic qualities, intended or not), while at the other are purely decorative ones with no genuine practical function at all.

All but the simplest cultures have evolved characteristic forms of architecture, and the more complex societies command a great variety of styles, techniques, and purposes that shape their buildings.

Architecture is treated in a number of articles in the *MACROPAEDIA*. For a general discussion of architecture and its history, see *Architecture, Art of*; *Architecture, History of Western*. For a discussion of the place of architecture and architectural theory in the realm of the arts, see *Aesthetics*. For related forms of artistic expression, see *Cities*; *Folk Arts*; *Decorative Arts and Furnishings*. For information on the particular styles and forms of architecture practiced by non-European peoples, see *African Arts*; *Central Asian Arts*; *East Asian Arts*; *Egyptian Arts and Architecture, Ancient*; *Islâmic Arts*; *Oceanic Arts*; *Prehistoric Peoples and Cultures*; *South Asian Arts*; *Southeast Asian Arts*.

For a description of the place of architecture in the circle of learning and for a list of both *MACROPAEDIA* and *MICROPAEDIA* articles on the subject, see *PROPAEDIA*: Part Six.

architrave, in Classical architecture, the lowest section of the entablature (horizontal member), immediately above the capital of a column. See *entablature*.

archives, also called **RECORDS**, or **RECORD OFFICE**, repository for an organized body of records produced or received by a public, semipublic, institutional, or business entity in the transaction of its affairs and preserved by

it or its successors. The term archives, which also designates the body of records themselves, derives from the French, and it, or a cognate, is used in most continental European countries and in the Americas. The terms records and record office are used in the United Kingdom and in some parts of the British Commonwealth.

Although the institution of archives and something of archival administration may be traced from antiquity, archives and archival administration as they are understood today date from the French Revolution. With the establishment of the Archives Nationales in 1789 and of the Archives Départementales in 1796, there was for the first time a unified administration of archives that embraced all extant repositories and record-producing public agencies. The second result was the implicit acknowledgment that the state was responsible for the care of its documentary heritage. The third result was the principle of accessibility of archives to the public.

Practice and principle have varied somewhat from country to country, but the pattern has generally been a central repository and, if conditions warrant them, provincial repositories. France has kept in the departmental archives not only the modern archives relating to the area but also those from the prerevolutionary period. The Netherlands has a central state archives and the provincial archives. The schism following World War II gave the Federal Republic of Germany a Bundesarchiv at Koblenz and the German Democratic Republic a central archives at Potsdam; but there are also repositories in the several *Länder*, or states. Italy has no single, central institution for state archives but has a series of important repositories, united under the ministry of the interior, which reflect the earlier divisions of the country. In the United States the National Archives was established in 1934 to house the retired records of the national government; the Federal Records Act of 1950 authorized the establishment also of "intermediate" records repositories in the several regions into which the country has been divided by the General Services Administration. Under the federal system of government each of the states of the United States independently has its own archival agency. In Canada, similarly, both the federal Ottawa government and the several provinces maintain their own archives. The Australian Archives has headquarters in Canberra and branches in all the state capitals and in Darwin and Townsville; the states have their own archives, usually under the management of state libraries.

The English Public Record Act of 1838 brought all separate collections together and placed them under the Master of the Rolls. England, therefore, is the outstanding example of centralization, whereas the more usual practice, as already suggested, is decentralization of archives to the domestic areas in which they originated. New Zealand's National Archives is similarly centralized, as are the archives of India and Pakistan. Japan has no national archives; its records still remain in the custody of ministries.

The United Nations and the several international organizations maintain archives. The International Council on Archives was founded in 1948 by professional archivists meeting in Paris under the auspices of UNESCO. Membership is open to all professional archivists and to representatives of (1) central archival directorates or administrations, (2) national or international regional associations of archivists, and (3) all archival institutions.

The science of records control has had to face at least three central issues: (1) the determination of types of records to be removed from agencies of origin, (2) the time of disposition, and (3) the manner of disposition. Practice has varied, but elimination usually has occurred before records have been transferred

from the agency of origin. Some countries, especially those whose history reaches back many centuries, have prohibited the elimination of records made before a specified date.

In the 20th century archivists have been faced with handling new kinds of records, such as photographic records, motion pictures, sound recordings, and computer-kept records. Microcopy, or microfilm, the legal status of which as record copy usually has had to be determined by special legislation, is a practical medium for making additional copies of records as security against risk through acts of warfare; as preservation against normal deterioration or damage; for use in international exchange; in lieu of loan or as a convenience to scholars; for reducing costs of repair, binding, and storage; as a means of supplementing by collateral materials the main bodies of records; and as a form of publication. Practice as well as belief has varied from country to country. As the concepts of social, economic, and cultural history developed, as industrialization played an increasingly prominent role in national and international affairs, as democratization spread over the surface of the globe, so there was an increasing awareness of the significance of business archives, institutional archives, and the papers of persons not necessarily distinguished. Germany was the first to recognize the value of business archives; Belgium, Switzerland, and The Netherlands followed shortly; France, England, Denmark, and the United States are examples, in varying degree and nature, of later recognition.

archivolt, molding running around the face of an arch immediately above the opening. The architectural term is applied especially to medieval and Renaissance buildings, where

Romanesque archivolt over the arches of the nave of Southwell Minster, Nottinghamshire, England, mid-12th century

By courtesy of the Courtauld Institute of Art, London

the archivolt is often decorated with sculpture, as in the archivolt on the west facade of Chartres cathedral (1140–50).

archlute, large 16th-century bass lute provided with additional bass strings, or diapasons, and producing a deeper sound that could be used in orchestral basso continuo parts. The diapasons were tuned according to individual preference, usually in a descending scale from the lowest principal string.

There were three main varieties of archlute: the chitarrone, theorbo (*qq.v.*), and theorbolute, or French lute. The angelica, or angel lute, of the 17th and 18th centuries, was related but had diatonically tuned strings and no frets.

archon, Greek ARCHON, in ancient Greece, the chief magistrate or magistrates in many city-states. The office became prominent in the Archaic period, when the kings (*basileis*) were being superseded by aristocrats.

At Athens the list of annual archons begins with 682 BC. By the middle of the 7th century BC, executive power was in the hands of nine archons, who shared the religious, military, and judicial functions once discharged by the king alone. The archon proper was the principal civil and judicial officer and may have presided over both Boule (Greek *boulē*, council) and Ecclesia (Greek *ekklesia*, assembly); as eponymous archon, he gave his name to his year of office.

Next came the polemarch, commander in war and judge in litigation involving foreigners. Third, the kingship survived in the *basileus*, who, as chief religious officer, presided over the Areopagus (aristocratic council) when it sat as a homicide court. Lastly there were six *thesmotelai* ("determiners of custom"), who dealt with miscellaneous judicial problems.

The potential power of the archons placed them under a variety of restrictions. Before entering office they had to undergo an examination (*dokimasia*) by the Boule and the law courts of birth qualifications, physical fitness, treatment of parents, and military activity; at the end of their term, they underwent an examination (*euthyna*) of their conduct, especially financial, while in office. Membership was originally open only to nobles by birth (*eupatrids* or *eupatridai*), who served as archons for life. The term of office was eventually reduced to 10 years, then to a single year, after which, since they could not be reelected, the archons became life members of the Areopagus. The eupatrid monopoly was broken c. 594 BC, when Solon made the top or top two property classes eligible for office.

Under the Cleisthenic constitution (508–c. 487), archons were elected directly by the Ecclesia; later they were chosen by lot from 500 previously elected candidates. Until 457 the office was still restricted to the top two classes. Then eligibility was first extended to the third property class; finally the fourth class was admitted in fact, though theoretically ineligible.

In the 5th century the authority of the archons declined. The polemarch lost his army command to 10 tribal commanders (*stratēgoi*), who also replaced the archons in the administrative sphere. The archons thus became primarily judicial officers. By the mid-5th century they no longer gave their own judgments but merely conducted preliminary inquiries (*anakrasis*), then brought the case before a jury, presiding over the hearing, but with no responsibility for directing the jury on matters of law.

Archons were also found at Delphi, Plataea, Phocis, and eastern and western Locris. During the 5th century the institution spread widely in the Aegean islands, mainly under Athenian influence, and then in the Hellenistic period to Anatolia.

Archon, in Gnosticism, any of a number of world-governing powers that were created with the material world by a subordinate deity called the Demiurge (Creator). The Gnostics were religious dualists who held that matter is evil and the spirit good and that salvation is attained by esoteric knowledge, or gnosis.

Because the Gnostics of the 2nd and 3rd centuries, who generally originated within Christianity, regarded the material world as outright evil or as the product of error, Archons were viewed as maleficent forces. They numbered 7 or 12 and were identified with the seven planets of antiquity or with the signs of the zodiac. Sometimes the Demiurge and the Archons were identified with the God, the angels,

and the law of the Old Testament and hence received Hebrew names. The recurring image of Archons is that of jailers imprisoning the divine spark in human souls held captive in material creation. The purpose of the gnosis sent from the realms of divine light beyond the universe through the divine emanation (aeon) Christ was to enable Gnostic initiates to pass through the spheres of the Archons into the realms of light.

archosaur, any of the various advanced reptiles of the subclass Archosauria ("Ruling Reptiles"), including all thecodonts, pterosaurs (flying reptiles), dinosaurs, bird ancestors, and crocodylians, the only extant order.

Early archosaurs appeared just prior to the beginning of the Triassic Period (245 to 208 million years ago). They probably derived from an earlier diapsid group and are associated with protorosaurs, rhynchosaurs, and trilophosaurids in a larger assemblage, the Archosauromorpha. All members of this assemblage were distinguished by an ankle specialization that facilitated upright posture. Most archosaurs had long hindlegs and short forelimbs. Nearly all were characterized by two pairs of openings in the skull above the eye (temporal fenestrae), to which jaw muscles were attached, and a large opening of uncertain function on the snout in front of the eye (antorbital fenestra). Unlike earlier reptiles, whose teeth were set in a shallow groove, the teeth of archosaurs were set in sockets.

Archosaurus, the earliest archosaur known from the fossil record, dates from the Late Permian Period (258 to 245 million years ago) and was found in Russia.

Archytas OF TARENTUM (fl. 400–350 BC, Tarentum, Magna Graecia [now Taranto, Italy]), Greek scientist, philosopher, and major Pythagorean mathematician, who is sometimes called the founder of mathematical mechanics. Plato, a close friend, made use of his work in mathematics, and there is evidence that Euclid borrowed from him for Book viii of his *Elements*. Archytas was also an influential figure in public affairs, and he served for seven years as commander in chief of his city.

A member of the second generation of followers of Pythagoras, the Greek philosopher who stressed the significance of numbers in explaining all phenomena, Archytas sought to combine empirical observation with Pythagorean theory. In geometry, he solved the problem of doubling the cube by constructing a three-dimensional model. The conclusions that he then drew concerning continued proportions, expressed as $a:b = b:c = c:d$, he applied to musical harmony. Thus, he was able to discern intervals of pitch in the enharmonic scale in addition to those already known in the chromatic and the diatonic scales. Rejecting earlier views that the pitch of notes sounded on a stringed instrument is related to the length or tension of the strings, he proposed instead that pitch is related to the movement of vibrating air. Incorrectly, however, he asserted that the speed at which the vibrations travel to the ear is a factor in determining pitch.

Archytas' reputation as a scientist and mathematician rests on his achievements in geometry, acoustics, and music theory, rather than on his extremely idealistic explanations of human relations and the nature of society according to Pythagorean number theory. Non-mathematical writings usually attributed to him, including a fragment on legal justice, are most likely the work of other authors.

Arcila (Morocco): see Asilah.

Arcimboldo, Giuseppe, Arcimboldo also spelled ARCIMBOLDI (b. c. 1527, Milan [Italy]—d. 1593, Milan), Italian Mannerist painter whose grotesque compositions of fruits,

"Summer," painting on canvas by Giuseppe Arcimboldo, 1563; in the Kunsthistorisches Museum, Vienna

By courtesy of the Kunsthistorisches Museum, Vienna, photograph, Erwin Meyer

vegetables, animals, books, and other objects were arranged to resemble human portraits. In the 20th century these double images were greatly admired by Salvador Dalí and other Surrealist painters.

Beginning his career as a designer of stained-glass windows for the Milan Cathedral, Arcimboldo moved to Prague, where he became one of the favourite court painters to the Habsburg rulers Maximilian II and Rudolph II. He also painted settings for the court theatre there and developed an expertise for illusionistic trickery. His paintings contained allegorical meanings, puns, and jokes that were appreciated by his contemporaries but lost upon audiences of a later date. His eccentric vision is epitomized in his portraits "Summer" and "Winter" (Kunsthistorisches Museum, Vienna).

Arciniegas, Germán (b. Dec. 6, 1900, Bogotá, Colom.—d. Nov. 29/30, 1999, Bogotá), Colombian historian, essayist, diplomat, and statesman whose long career in journalism and public service strongly influenced the cultural development of his country in the 20th century. His contributions abroad as an educator and diplomat played an important role in introducing North Americans and Europeans to Spanish-American history and contemporary culture.

Arciniegas became a prominent figure in public life soon after his graduation from the law school of the National University of Colombia in Bogotá in 1924. He contributed essays to several newspapers and magazines, founding the review *Universidad* ("University") in Bogotá in 1928 and becoming editor of the newspaper *El tiempo* ("The Times") there in 1939. Also active in education, he served as Colombian minister of education (1941–42 and 1945–46) and taught at several universities in the United States, including Columbia (1947–57).

Arciniegas published numerous volumes on diverse aspects of Latin-American culture and history that reveal his original perceptions as well as his encyclopaedic knowledge. Such works as *Biografía del Caribe* (1945; *Caribbean, Sea of the New World*) and *El continente de siete colores* (1965; *Latin America: A Cultural History*) introduced an international audience to Arciniegas' panoramic view of his continent.

In his 50s, Arciniegas turned to a diplomatic career. In 1959 he was appointed Colombian ambassador to Italy; later he also served in Is-

rael, Venezuela, and Vatican City. He became dean of the faculty of philosophy and letters at the University of the Andes, Bogotá, in 1979.

Arcos de la Frontera, city, Cadiz provincia, in the *comunidad autónoma* ("autonomous community") of Andalusia, southern Spain. It is located on a high rock bounded on three sides by the Guadalquivir River. Rich in Moorish architecture, the city also contains the Gothic churches of Santa María de la Asunción and San Pedro, with additions dating from the 16th to the 18th century. Called Colonia Arcensium by the Romans and Medina Arkosh by the Moors, Arcos was taken for the Christians by Alfonso X of Castile in 1264 and was made a city in 1472. In medieval times it was on the border between Christian and Muslim Spain. It is now an agricultural centre and manufactures cork and esparto products. Pop. (1999 est.) 27,948.

Arcoṭ, city, northeastern Tamil Nādu state, southeastern India, on the Pālār River. Located at the point where the Pālār River valley meets the Coromandel Coast, it commands the inland route from Madras to Bangalore, between the Mysore Ghāt and the Javādi Hills. A fortified capital of the Muslim nawabs, Arcoṭ was the scene of numerous battles between the Muslims, Marāṭhās, French, and British in the 17th and 18th centuries. In the second half of the 20th century it was superseded in importance by Vellore. Pop. (1991) city, 45,205; metropolitan area, 114,760.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Arctic, northernmost region of the Earth, centred on the North Pole and characterized by distinctively polar conditions of plant life, climate, and so on.

A brief treatment of the Arctic follows. For full treatment, see MACROPAEDIA: Arctic.

Unlike the Antarctic continent, which is surrounded by ocean, the Arctic is composed largely of an ocean basin that is almost completely surrounded by continents. Included in the Arctic region are the northern reaches of Canada, Alaska, Russia, Norway, the Atlantic Ocean, Svalbard, most of Iceland, Greenland, and the Bering Sea. The region is not coextensive with the area enclosed by the Arctic Circle—a line drawn at about 66° 30' N, marking the southern limit of the zone in which there is at least one annual 24-hour period during which the Sun does not set and one during which it does not rise. A more useful line to mark the Arctic's southern boundary might be the northernmost tree line on the continents, but no universally agreed boundary exists.

The land. The Arctic land areas surrounding the Arctic Ocean are generally flat and low-lying. Greenland and the eastern Canadian Arctic have distinctive highlands, where mountains and plateaus exceed 6,600 feet (2,000 m) in elevation over wide areas; much of the Greenland ice sheet rises above an elevation of 8,200 feet (2,500 m). Less continuous uplands occur in the Lena River delta and the peninsula of northeastern Siberia in Russia, while a narrower but higher belt of mountains is found in Alaska, where Mount McKinley (Denali) reaches an elevation of 20,320 feet (6,194 m).

Three shields—the Canadian-Greenland, the Baltic, and the Angaran—constitute the main structural features of the Arctic. The shield rocks are generally covered by flat-lying Paleozoic sedimentary rocks and fringed by orogenic belts of sedimentary rocks of Paleozoic and younger age, which include the fold mountains of the Urals and Novaya Zemlya islands in Russia. The shields contain rich mineral reserves of iron, nickel, copper, and zinc, while the sediments flanking them con-

tain reserves of coal and oil. Early oil discoveries in the folded sequences of northern Alaska have been followed by exploration eastward along the line of the folded structures in Arctic Canada and northern Greenland and into equivalent structures of the Barents Sea and Svalbard. The rich oil and gas reserves associated with the sediments in western Siberia are immensely important on a world scale. Active earthquake regions with associated volcanic activity are located in the Cordillera of southern Alaska. Three of the world's largest rivers, the Ob, the Yenisey, and the Lena, flow northward through the Russian Arctic and empty into the Arctic Sea. The dominant feature of Arctic rivers is their intense seasonality of flow. Discharge during the summer is generally low but very sensitive to rainstorms, because permafrost and scanty vegetation provide little interception to rainwater. In the summer, water temperatures rise as high as 60° F (19° C), and thermal erosion causes riverbanks to collapse. Rivers whose basins lie wholly within the Arctic, such as the Colville in Alaska, hold hardly any water in winter. Rivers like the Ob and Mackenzie, however, whose headwaters lie in lower latitudes, maintain flow throughout the year.

More than three-fifths of the Arctic's land surface is ice-free, and the glaciation limit varies considerably with local conditions. The climate in much of the ice-free area is moderately continental with long, cold, and relatively dark winters, although the darkness is far from absolute. The length and darkness of winter increases toward the pole because of the low angle of the sun in relation to the ground surface. The snow cover is patchy and thin, and during spring and early summer the ground becomes saturated and boggy with melted snow. The coastal areas experience warmer winters and cooler summers. Summer temperatures over the Arctic Ocean approximate 32° F (0° C), while the surrounding land areas are warmer, often exceeding 60° F (15° C), as in northeast Siberia. Arctic topography generally favours a northward movement of warm air in winter over the Atlantic sector. The pole is kept warm in comparison to surrounding land by the existence of Arctic Ocean water below a relatively thin layer of ice. Precipitation is light, and most of the zone is arid. Annual precipitation is generally less than 5 inches (130 mm) inland, while the coasts may receive close to 10 inches (260 mm) annually. This variance in precipitation is more pronounced in the case of the North American Arctic than in the Russian Arctic. Cyclones and blizzards are common, as the generally treeless land areas and the relatively smooth ice surfaces over the sea provide no friction against the wind.

Apart from the Greenland ice sheet, the glaciers in the region are restricted to the eastern uplands of the Canadian Arctic and the maritime islands and peninsulas off northwestern Eurasia. Glaciers are generally characterized by extensive layers of ice built up on a flat land area and superimposing a roughly radial outflow of ice over the area. The Greenland glacier, covering an area of approximately 650,000 square miles (1,700,000 square km), is the largest glacier in the Northern Hemisphere. It is contained within a saucer-shaped depression, and in the centre the base of the ice is more than 1,000 feet (300 m) below sea level. Iceland has five major glaciers, the largest of which, Vatna Glacier, covers more than 3,000 square miles (7,800 square km). Cirque glaciers, occupying armchair-shaped hollows, are found in northeastern Siberia and the Brooks Mountain Range in Alaska. The North American and Eurasian ice sheets are in retreat, and the continued existence of the Greenland ice sheet is largely due to the fact that its depressed centre is essentially land-bound and thus shielded from sapping by sea.

The extensive land area immediately surrounding the glaciers in the Arctic is characterized by the presence of permafrost. Permafrost is permanently frozen earth where the temperature is constantly below 32° F (0° C). In North America most of the Arctic area north of the tree line lies in a zone of continuous permafrost; in the Russian Arctic the permafrost is continuous north of the tree line and east of the Ural Mountains. Near the northern coast of each continent, permafrost extends to depths of 1,500 to 2,000 feet (450 to 600 m), and nearly four-fifths of its volume is ice.

Two main vegetation zones may be identified in the Arctic: the subarctic circumpolar boreal forest and the tundra. The two zones are separated by the tree line. All Arctic plants must contend with a harsh environment of low temperatures, periods of continuous summer daylight and continuous winter darkness, infertile and often mobile soils and permanently frozen ground, and strong winds marked by low humidity. The representative plant species are few in number and are frequently dwarfed. The Eurasian forest consists primarily of larch, pine, and fir; white spruce, black spruce, and occasionally larch are found in North America. Flowering plants near the tree line include blue-spiked lupine, wild crocus, arctic poppy, and saxifrage.

Tundra areas have a continuous cover of vegetation, and several plant communities are recognized. Heath tundra, of lichens and mosses with few flowering plants, predominates. Sedges and grasses are found in the moister areas of tussock or hillock tundra. Dwarf shrubs, willow, birch, and juniper may be found in warmer parts of the heath tundra.

The Arctic's animal life is influenced both by vegetation characteristics and by the climate. The zonal decrease in vegetation northward is mirrored by decreasing animal populations. The caribou occurs on the North American and Asian continents, and musk-ox roam most of the Arctic tundra. A huge population of geese inhabits eastern Greenland. Carnivores include the Arctic wolf, Arctic fox, and snowy owl. There are no reptiles in the Arctic, owing to the absence of frost-free winter refuges.

The people. Though many nations participated in the exploration of the Arctic, only the Russians, Norwegians, Swedes, and Finns settled; Russians predominate numerically in the Arctic. The region is one of the most sparsely populated in the world. The settlement pattern is varied. Several cities in the Russian Arctic have populations of more than 100,000, while in Greenland and Svalbard, towns have populations of less than 10,000. The chief native population groups are the Sami (Lapps) of Europe, the Nenets of western Russia, the Inuit and Eskimos of North America, the Nordic Caucasians of Iceland, the Greenlanders (also Inuit in heritage) of Greenland, and the Yakuts, Tungus, Yukaghirs, and Chukchis of eastern Russia. There has been considerable immigration since the 1930s, and in the late 20th century immigrants (defined as peoples arriving from a relatively developed southern culture who continue to draw support from that culture) outnumbered natives 7 to 1.

The economy. The inability to plant crops has been a fundamental constraint to economic activity in the Arctic, and yet almost all indigenous populations are self-sufficient, drawing almost entirely on resources from the sea. The waves of economic exploitation that have intruded into the Arctic from the rest of the world, however, are gradually transforming its economic landscape. Oil and other minerals are extracted from the Arctic by North American, European, Russian, and Japanese companies. The coastal Arctic is exploited for seals, and inland areas are exploited for furs.

Arctic development plans of the administrative powers have been markedly different. The Soviet system was based on long-term plan-

ning, supported by massive investment over decades, for large-scale development. In the North American system, planning has tended to follow short-term economic exploitation, and infrastructure investments take place only when necessitated by economic demands. The Danes, by artificially protecting Greenland from the rest of the world, have reduced economic exploitation and enabled themselves to carry out significant infrastructural development. Economic and strategic exploration of the Arctic is closely linked with lines of communication, which run inland from the more populated coastline to areas where one or more resources are exploited.

High labour and transport costs and tremendous capital investment are typical of all areas of the Arctic. Transient labour makes creation of settled communities difficult. The construction of transport arteries to link the Arctic with the main land masses is vital to long-term development. Indigenous populations of the Arctic generally have a low level of participation in development, and many have suffered the loss of land or resources essential to their traditional ways of life.

Government and social conditions. The Russian Arctic, constituting by far the largest national unit within the Arctic region, is administered by Russia, the Alaskan Arctic by the United States, and the Canadian Arctic by Canada. The Norwegian Arctic of the Svalbard archipelago and the northern mainland is subject to the constitutional monarchy of Norway. Iceland is a parliamentary democracy with an elected president as head of state; Greenland is a self-governing part of the Danish realm.

Although the provision of health services is difficult in such terrain, standards in all countries are good. Health services on the North American continent in the early 1980s involved a vigorous attack on tuberculosis, which had become widespread. Nutritional intake is very high, because of the extreme climate; average food supplies per capita in the Arctic region range from 110 percent of the United Nation's recommended requirements in Iceland to as much as 158 percent on the Russian mainland. Average life expectancy in the Arctic ranges from 62 years in Greenland to 75 years in Norway.

The encroachment of the cultural modes and standards of the nations that claim portions of the Arctic has tended to destroy the traditional cultures of the indigenous peoples of the region. Modern Arctic settlements range from isolated scientific-research stations to sizable mining towns and local administrative centres with schools and churches.

History. The earliest inhabitants of the Arctic were probably the Paleo-Siberians, who lived in the unglaciated lowland of northeastern Siberia about 5000 BC. The first of two waves of hunting-and-gathering cultures emerged about 2000 BC, originating in Siberia and sweeping across Arctic Canada to northern Greenland. The second wave originated in the Bering straits about AD 10 and extended along the Canadian straits as far as Greenland. These large-scale migrations were probably due to environmental changes and the availability of game. Hunting and gathering came to be gradually replaced by farming. In some areas the development of reindeer herding, which involved following the reindeer into the tundra in summer and retreating to the forests in winter, necessitated a nomadic existence.

The Russians were the first to explore the Arctic region with an expedition to Russia's northeastern lands in 1733 that lasted more than 10 years. Other smaller expeditions were directed principally toward geographic exploration of coastal lands. By the latter part of the 19th century, most of the Arctic region's

coastline had been charted. The 1879 expedition of G.W. DeLong in search of possible new lands north of Siberia ended when his ship sank, crushed by an ice pack. During 1893–96 the Norwegian explorer Fridtjof Nansen successfully navigated the ocean passage from the New Siberian Islands to Spitsbergen. In 1937 the Soviet Union landed an airplane equipped with skis on Arctic ice and established a scientific station.

The years following World War II (1939–45) led to the establishment and maintenance of Arctic weather and scientific observatories that accumulated an enormous body of data. In 1958 the USS *Nautilus* and *Skate* voyaged beneath the ice cap, and in 1978 the Soviet nuclear ice-breaker *Sibir* opened a southern passage across the coast of northern Siberia.

Arctic Circle, parallel, or line of latitude around the Earth, at approximately 66°30' N. Because of the Earth's inclination of about 23½° to the vertical, it marks the southern limit of the area within which, for one day or more each year, the Sun does not set (about June 21) or rise (about December 21). The length of continuous day or night increases northward from one day on the Arctic Circle to six months at the North Pole. The Antarctic Circle is the southern counterpart of the Arctic Circle, where on any given date conditions of daylight or darkness are exactly opposite.

Arctic fox, also called **WHITE FOX**, or **POLAR FOX** (species *Alopex lagopus*), northern fox of the family Canidae, found throughout the Arctic, usually on tundra or mountains near the sea. In adaptation to the climate, it has short, rounded ears, a short muzzle, and fur-covered soles. Its length is about 50–60 cm (20–24 inches), exclusive of the 30-centimetre tail; and its weight is about 3–8 kg (6.6–17 pounds). Coloration depends on whether the animal is of the "white" or the "blue" colour phase. Individuals of the white phase are grayish brown in summer and white in winter, while those of the blue phase (blue foxes of the fur trade) are grayish in summer and gray-blue in winter.

"White" phase of Arctic fox changing to its summer coat

Russ Kinne—Photo Researchers/EB Inc

The Arctic fox is a burrow dweller and may be active at any time of day. It feeds on whatever animal or vegetable material is available and often follows polar bears to feed on the remains of their kills. It usually breeds once yearly, a litter of up to 14 dark-furred pups being born between April and June; gestation is about 52 days.

Arctic Ocean, smallest of the world's oceans, centring approximately on the North Pole.

A brief treatment of the Arctic Ocean follows. For full treatment, see **MACROPAEDIA: Arctic**.

The Arctic Ocean is almost completely surrounded by the landmasses of Eurasia, North

America, and Greenland and is distinguished by a cover of ice. The ocean is divided into two major basins, the Eurasia and the Amerasia, which are separated by the Lomonosov Ridge. Each is further subdivided—the Eurasia into the Fram and Nansen basins, which are separated by the Nansen Cordillera; and the Amerasia into the Makarov and Canada basins, separated by the Alpha Cordillera. The Eurasia Basin was formed by seafloor spreading along the axis of the Nansen Cordillera, which began under the edge of the Asian continent. The origin of the Amerasia Basin is less clear, but it may have opened by rotation of the Arctic-Alaska lithospheric plate away from the North American Plate during the Cretaceous Period (about 144 to 66.4 million years ago). The sediments of the ocean floor show that at least part of the Arctic Ocean was relatively warm prior to 40 million years ago.

Several factors make the Arctic's physical, chemical, and biological processes significantly different from those of the adjoining North Atlantic and Pacific oceans. The ice pack reduces the exchange of energy between the ocean and atmosphere by a factor of about 100 and reduces the penetration of sunlight necessary for the photosynthetic processes of marine life. The Arctic Ocean is also distinguished by a high ratio of shallow marginal seas to deep basins; the former occupy about 36 percent of the ocean's surface area but contain only 2 percent of its volume.

The major circulation into and from the Arctic Basin is through the Fram Strait, which lies between Svalbard and Greenland. Circulation of this cold water into the Atlantic contributes to the mean temperature of the world ocean and affects the global climate.

All Arctic waters are cold, and variations in their density are determined by changes in their salinity. A thin and less dense surface layer of water is separated by a strong density gradient from the main body of water, which is of uniform density. Three major water masses and one lesser mass may be identified. The Arctic water from the surface to a depth of 650 feet (200 m) is the most variable because of the continual freezing and thawing cycle and because of additions of fresh water from rivers and from precipitation. Its temperatures may vary over a range of 7° F (4° C). Warmer Atlantic water underlies this layer to a depth of about 3,000 feet (900 m). This water is gradually cooled to a maximum of about 33° F (91° C). Bottom water extends to the ocean floor; it is somewhat colder but similar in salinity. An inflow of Pacific water of warmer temperature and greater salinity may be observed in the Chukchi Sea, flowing as a wedge between the Arctic and Atlantic waters.

Between about 60° N and 75° N the occurrence of sea ice is seasonal; above 75° N it is relatively permanent. As sea ice forms the salt is expelled from it as brine. By the time the sea ice is one year old, it is sufficiently salt-free to be melted for drinking. This salt-free ice is referred to as polar pack and is smooth and pale blue in colour. Younger ice is more jagged and grayer; it has a characteristic thickness of about 6 feet (2 m), whereas older ice averages twice that thickness. Area 4,732,000 square miles (12,257,000 square km); maximum depth 18,050 feet (5,502 m).

Arctolepis, extinct genus of Early Devonian fishlike animals (408 to 387 million years ago), considered to be an early and primitive member of a group known as the arthrodires, or jointed-neck fishes. *Arctolepis* had a bony head and trunk shield but was unarmoured behind the trunk region; the body tapered to a pointed tail; a tail fin was developed only on the lower margin of the tail. *Arctolepis* was a small animal, less than 30 cm (12 inches) in length but with enormously developed pectoral spines that must have been some aid to

Arctolepis, of Early Devonian Period

swimming but could hardly have been very efficient.

Arcturus, also called **ALPHA BOÖTIS**, one of the five brightest stars in the night sky, and the brightest star in the northern constellation Boötes, with an apparent visual magnitude of 0.00. It is an orange-coloured giant star about 40 light-years from the Earth. It lies in an almost direct line with the tail of Ursa Major (the Great Bear); hence its name, derived from the Greek words for "bear guard."

Arculf (fl. late 7th century, Germany), bishop who was the earliest Western Christian traveler and observer of importance in the Middle East after the rise of Islām. Although he most likely was connected with a monastery, some believe he was the bishop of Périgueux, Aquitaine.

On his return from a pilgrimage to the Holy Land (c. 680), Arculf was driven by storm to Scotland and so arrived at the Hebridean island of Iona, where he related his experiences to his host, Abbot St. Adamnan. Adamnan's narrative of Arculf's journey, *De locis sanctis*, came to the attention of the Venerable Bede, who inserted a brief summary of it in his *Ecclesiastical History of the English People*. Bede also wrote a separate and longer digest that endured throughout the Middle Ages as a popular guidebook to the Eastern holy places.

Among the places Arculf visited were the sacred sites of Judaea, Samaria, and Galilee; Damascus and Tyre; and the Nile River and the volcanic islands of Aeolia (modern Eolie Islands). He drew plans of the churches of the Holy Sepulchre and of Mount Zion in Jerusalem, of the Ascension on Olivet, and of Jacob's Well at Shechem. His records also include the first form of the story of St. George, patron saint of England.

Ard Mhacha (Northern Ireland): see **Armagh**.

Arda River, Greek **ÁRDHAS**, river in Bulgaria, rising in the central Rhodope Mountains near the town of Smolyan and following a 180-mile (290-kilometre) course eastward past Kürdzhalı and Ivaylovgrad to enter the Maritsa just west of Edirne, Tur., after a 23-mile (37-kilometre) course in Greece. The Bulgarian section has three hydroelectric and irrigation dams, among the largest in Bulgaria. In the upper valley are the mining towns of Rudozem, Madan, and Smolyan on the tributary Cherna River. The Arda River valley is known for its tobacco growing.

Ardaban (Persian statesman): see **Artabanus**.

Ardabil, Turkish **ERDEBİL**, town, northwestern Iran, 38 miles (61 km) from the Caspian Sea. It stands on an open plain 4,500 feet (1,400 m) above sea level, just east of Mount Sabalan (15,784 feet [4,811 m]), where cold spells occur until late spring. Persian historians have ascribed a founding date to the town in the Sāsānian period, but its known history does not begin until the Islāmic period. The town was taken by treaty by 'Alī (c. 600–661), the fourth caliph. It was at that time the residence of the Sāsānian governor. The Umayyad gov-

ernor made Ardabil his capital, but the Arab hold on the region did not last. Local rulers fought continuously in the area until the Mongol conquest in 1220, when the town was destroyed. It lost all importance until Sheikh Šafī od-Dīn made it the centre of his Šūfī order in the 13th century, at the beginning of the rise of the Šafavid dynasty. Ardabil became a Šafavid shrine, especially enriched by gifts from Šafavid rulers. Much of the library of the shrine, once the greatest in Iran, and many of the treasures were looted by the Russians after their sack of Ardabil in 1827.

The town once shared in trade with Russia via the Caspian, but such activity has stagnated. Its industry consists of a cement factory and the making of carpets and rugs. Local warm mineral springs are frequented. The population speaks Azeri, a Turkic language. Pop. (1991) 311,022.

Ardabil Carpet, either of two Persian floor coverings that are among the most famous examples of early classical Persian workmanship. The larger one measures 34 feet by 17.5 feet (10.4 by 5.3 m), and both carpets have a silk warp and wool pile. The carpets were completed in 1539–40, during the reign of the Šafavid ruler Shah Tahmāsp I (1524–76), and they were originally laid in the Mosque of Ardabil, in the Iranian province of Azerbaijan. Both carpets have a rich, exquisitely detailed and organized design in which a deep indigo field is covered with delicate, intricate floral tracery and a central medallion of pale yellow terminates in 16 minaret-shaped points with almond pendants.

Both Ardabil carpets bear the inscription "I have no refuge in the world other than thy threshold; My head has no protection other than this porch way; The work of the slave of the Holy Place, Maksoud of Kashan, in the year 946 [AD 1539–40]." Both carpets had been damaged by the late 19th century, and parts of the smaller one (which is now in the Los Angeles County Museum of Art) were used to mend the larger one (now in the Victoria and Albert Museum, London).

Ardagh Chalice, large, two-handled silver cup, decorated with gold, gilt bronze, and enamel, one of the best-known examples of Irish ecclesiastical metalwork. It was discovered in 1868, together with a small bronze cup

Ardagh Chalice, chased silver with gold inlay, gilt bronze, and enamel, Irish, c. 720; in the National Museum of Ireland, Dublin

By courtesy of the National Museum of Ireland, Dublin

and four brooches, in a potato field in Ardagh, County Limerick, Ire. The decoration consists mainly of panels of fine gold and silver filigree applied to the otherwise plain body of the vessel. Studs set with coloured enamels are arranged at intervals amid the filigree decoration, which combines interlaced animal forms and spirals with repeating abstract patterns. The outside of the bowl is engraved with the Latin names of some of the Apostles. There are similarities between the letters of this inscription and some of the large initials in the

celebrated manuscript known as the Lindisfarne Gospels, which likely dates from about AD 710–720. Thus, the chalice is thought to date from the first half of the 8th century.

It has so far proved impossible to attribute its manufacture to any particular workshop, but affinities do exist between the filigree decoration on the chalice and the decoration of the celebrated Tara brooch. Another well-known example of Irish ecclesiastical metalwork, the Moylough belt-reliquary is also decorated in a similar manner. It is likely that the Ardagh Chalice formed part of the treasury of some early Irish church or monastery, until it was disestablished and the cup was concealed for safekeeping. It is now housed in the National Museum of Ireland at Dublin.

Ardashīr, Old Persian ARTAKHSHATHRA, name of Sāsānian kings, grouped below chronologically and indicated by the symbol ●.

● **Ardashīr I** (fl. mid-3rd century), the founder of the Sāsānian empire in ancient Persia (reigned AD 224–241).

Ardashīr was the son of Bābak, who was the son or descendant of Sāsān and was a vassal of the chief petty king in Persis, Gochīhr. After

Ardashir I, coin, 3rd century; in the British Museum

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd

Bābak got Ardashīr the military post of *ar-gabad* in the town of Dārābgerd (near modern Darab, Iran), Ardashīr extended his control over several neighbouring cities. Meanwhile, Bābak had slain Gochīhr and taken the title of king. Although Bābak's request that the Parthian king Artabanus V allow him to transmit the crown to his eldest son, Shāpūr, was refused, Shāpūr nevertheless succeeded him. In the ensuing struggle between him and Ardashīr, Shāpūr was killed, and Ardashīr was crowned king of Persis in 208. Having suppressed a revolt in Dārābgerd, he gradually conquered the neighbouring province of Kermān and the coastal Persian Gulf lands. He made his capital at Gūr (modern Firūzābād), which he renamed Ardashīr-Kwarrah.

Ardashīr then moved against western Iran, taking Ešfahān, Kerman, Elymais, and Mesene. Withdrawing again to Persis, he met the Parthian army at Hormizdagān (site unknown) in AD 224 and won a decisive victory, slaying Artabanus. Soon after, Ardashīr entered the Parthian capital of Ctesiphon, in Mesopotamia, in triumph and was crowned "king of kings of Iran."

With his son and successor, Shāpūr I, Ardashīr established the Sāsānian empire. Nothing is known of Ardashīr's personal life; his deeds, however, indicate that he was ruthless, a great soldier, and a capable king. He founded or rebuilt many cities and is credited with digging canals and building bridges. Several great rock carvings commemorate his reign.

Ardashīr made Zoroastrianism the state religion, and he and his priest Tosar are credited with collecting the holy texts and establishing a unified doctrine. Two treatises, *The Testament of Ardashīr* and *The Letter of Tosar*, are attributed to them. As patron of the church, Ardashīr appears in Zoroastrian tradition as a sage. As founder of the dynasty, he is cele-

brated in a 5th-century book in Pahlavi, the *Karnamag-i Ardashīr*.

● **Ardashīr II** (fl. late 4th century), king of the Sāsānian empire in ancient Persia (reigned AD 379–383). During the reign of his brother Shāpūr II, he had been king of Adiabene (now a region of northeast Iraq), where he took part in the persecution of Christians. After Shāpūr's death, he was set on the throne by the nobles, presumably at an advanced age. His investiture is commemorated in a rock carving at Tāq-e Bostān. His attempts to assert himself were futile, and he was soon deposed.

Ardea, ancient town of the Rutuli people, and now a modern village in Roma *provincia*, Lazio *regione*, west-central Italy. It lies 23 miles (37 km) south of Rome. In ancient times it was an important centre of the cult of Juno. Ardea developed into one of the most important Latin cities and was a member of the Latin leagues of the 6th and 5th centuries BC. In 444 the town signed a treaty with the Romans, who, according to Livy, colonized it as a barrier against the Volsci. The decline of Ardea, from the 4th century onward, was hastened by malaria and the Roman civil wars under Marius and Sulla in the 1st century BC. Pop. (1993 est.) mun., 18,074.

Ardèche, *département*, Rhône-Alpes *région*, southern France. It was formed in 1790 from the Vivarais district of Languedoc. It occupies the Cévennes edge of the Massif Central and is a highland region that is deeply scored by torrents feeding the Ardèche River flowing to the Rhône, which forms its eastern boundary. North of the Ardèche River valley, the volcanic hills of the Coirons jut out southeast toward the Rhône River valley, and in the west Mount Mézenc, part of the Velay volcanic plateau, rises to 5,755 feet (1,754 m). The upper Allier River forms part of the *département's* western boundary. The sheltered valleys near the Rhône River are warm, but winter is severe on the higher ground.

Fruit trees, vines, and even olives are grown in the lower valleys, and some meadows are irrigated to bring in more than one hay crop each summer. Cereals, potatoes, and fodder crops grow in the bottomlands, and chestnuts are harvested at elevations as high as 2,500 feet (750 m). There are still high summer pastures for sheep and cattle, but the heights are almost denuded of woodlands. The *département* has large cement plants along the Rhône River valley.

The main road from Le Puy to the Rhône valley traverses the region by the Ardèche River valley. Privas, the capital, heads an *arrondissement*, as do Largentière and Tournon. The court of appeal is outside the *département* at Nîmes. The countryside, especially in the west, has become depopulated during the last century. Area 2,135 square miles (5,529 square km). Pop. (1992 est.) 279,793.

Arden, John (b. Oct. 26, 1930, Barnsley, Yorkshire, Eng.), one of the most important of the British playwrights to emerge in the mid-20th century. His plays mix poetry and songs with colloquial speech in a boldly theatrical manner and involve strong conflicts purposely left unresolved.

Arden grew up in the industrial town of Barnsley, the character of which he captured in his play *The Workhouse Donkey* (1963). He studied architecture at the University of Cambridge and at Edinburgh College of Art, where fellow students performed his comedy *All Fall Down* (1955), about the construction of a railway. He continued to write plays while working as an architectural assistant from 1955 to 1957. His first play to be produced professionally was a radio drama, *The Life of Man* (1956), about the fatal voyage of a boat

captained by a madman. *Waters of Babylon* (1957), a play with a roguish but unjudged central character, revealed the moral ambiguity that troubled critics and audiences in later dramas. His next two plays, *Live Like Pigs* (1958) and *Serjeant Musgrave's Dance* (1959), also caused controversy.

In 1957 Arden married Margaretta D'Arcy, actress and playwright, with whom he wrote a number of stage pieces and improvisational works for amateur and student players. *The Happy Haven*, produced in 1960 in London, is a sardonic farce about an old people's home. *The Workhouse Donkey* is a crowded, exuberant, and comic drama of municipal politics. *Armstrong's Last Goodnight* (1964), written in lowland Scots vernacular, is a drama of struggle between a courtier and a freebooter, pointing to resemblances between 16th-century Scotland, its setting, and the contemporary Congo. *Left-Handed Liberty* (1965), written on the occasion of the 750th anniversary of the signing of Magna Carta, characteristically dwells on the failure of the document to achieve liberty. *The True History of Squire Jonathan and His Unfortunate Treasure* (1968) is an erotic "duologue" adapted to the then current fad of nudity on stage, and *The Island of the Mighty* (1972), written in collaboration with Margaretta D'Arcy, is a non-Romantic ballet-drama about King Arthur. Later plays include *The Non-Stop Connolly Cycle* (1975), *Vandaleur's Folly* (1978), and *The Little Gray Home in the West* (1978).

Ardennes, also spelled ARDENNE, wooded plateau covering part of the ancient Forest of Ardennes, occupying most of the Belgian provinces of Luxembourg, Namur, and Liège; part of the Grand Duchy of Luxembourg; and the French *département* of Ardennes. It is an

The wooded hills of the Ardennes in Belgium
Thomas B. Hollyman—Photo Researchers/EB Inc

old plateau comprising the western extension of the Middle Rhine Highlands, stretching in a northeast-southwest direction and covering more than 3,860 sq mi (10,000 sq km). Its geological history is complex; as a result of intense folding, faulting, uplifts, and denudations, some older strata of rock have been thrust over younger strata.

The name Ardennes used in a strict sense refers to the southern half of the area, where the elevations range from 1,150 to 1,640 ft [350 to 500 m], though the high point at Botrange, south of Liège, is 2,277 ft. This part consists of sandstone, quartzite, and some slate and limestone. Its rounded summits are separated by shallow depressions containing peat bogs, from which rise many rivers that cut narrow and sinuous valleys. These High Ardennes form the watershed between rivers flowing north and west to the Meuse River and south and east to the Moselle River. Heavy precipitation, combined with low clouds, fog, and frost, make the uplands distinctly bleak. Although one-half of the area is covered by forest, the thin, acid, and waterlogged soil is generally infertile, supporting only heath.

The northern part is much lower, between 655 and 985 ft. Most of the small farmland is under permanent grass for pasture, but there is some cultivation of oats, rye, potatoes, and clover in the valleys. Cattle are raised mainly for dairy production, pigs for the ham that has long been a local specialty of the Ardennes, and sheep for a small wool industry. Cattle hides are processed with the abundant local supplies of tannin from the oak trees. Stone quarrying is widespread, but mining and manufacturing are limited.

Despite a certain raw inhospitality of the area, its economy increasingly depends upon the development of tourism. The Ardennes has one of the lowest population densities of Europe, but it is located in the middle of the heavily populated triangle of Paris-Brussels-Cologne. Mineral springs at Spa, Belg. (whence the English word spa), have made it a favourite health resort since the 16th century. The lonely forests offer respites for central Europeans from the pressures of the surrounding urbanization.

During World Wars I and II, the Ardennes became a battleground, the scene of bitter fighting in 1914, 1918, and 1944 (Battle of the Bulge; *q.v.*).

Ardennes, *département*, Champagne-Ardennes region, northeastern France, bordering on Belgium, covering an area of 2,015 sq mi (5,219 sq km) and including the southwest margin of the Ardennes highland and the adjacent lowlands in the Meuse and Aisne valleys, which are connected by the Ardennes Canal. The Meuse turns northwest after leaving Lorraine, and from Charleville-Mézières to Givet on the frontier it flows in deeply entrenched meanders, some of which provide defensive points marked by castle towns. The rugged Argonne Massif pushes north into the southeastern part of the *département*, drained by the Aisne River. The Aisne Valley and the flanking chalk country are well cultivated (grains and sugar beets), but there are heavy forests in the Argonne and Ardennes.

Although unfavourable terrain for manoeuvre, the region has been the scene of battles since the French Revolution, including the campaign of 1794, the Franco-German War (with Napoleon III's surrender at Sedan, 1870), the Battle of the Ardennes in World War I and the bitter U.S.-German fighting in the Argonne in 1918, the German breakthrough near Sedan in 1940 that marked the Battle of France, and the final offensive action in France by the Germans in December 1944 (Battle of the Bulge; *q.v.*).

Sedan on the Meuse and Rethel on the Aisne have long-established woollen mills. Charleville-Mézières has wood-working and iron industries. There is a nuclear power plant at Chooz (270 mW; operational since 1967). Charleville-Mézières (the capital), Sedan, Rethel, and Vouziers head *arrondissements*. The appeal court is at Nancy, and education is directed from Reims. Pop. (1982) 302,338.

Ardennes, Battle of the (1944-45): *see* Bulge, Battle of the.

Ardhanārīśvara (Sanskrit: Lord Who Is Half Woman), composite male-female figure of the Hindu god Śiva, together with his consort Pārvatī. As seen in many beautiful Indian and Southeast Asian sculptures, the right (male) half of the figure is adorned with the traditional ornaments of Śiva. Half of the hair is piled in a hairdress of matted locks, half of a third eye is visible on the forehead, a tiger skin covers the loins, and serpents are used as ornaments. The left (female) half shows hair well combed and knotted, half of a *tilaka* (a round dot) on the forehead, the eye outlined in black, one well-developed breast, a silk garment caught with girdles, an anklet, and the foot tinted red with henna.

The symbolic intent of the figure accord-

Ardhanārīśvara, stone sculpture, Cōja period; in the Nāgeśvarasvāmin temple, Kumbakonam, India

By courtesy of the Archaeological Survey of India, New Delhi

ing to most authorities is to signify that the male and female principles are inseparable. A popular explanation, as given in a collection of legends known as the *Śiva-Purāṇa*, is that Brahmā created male beings and instructed them in turn to create others, but they were unable to do so. When Śiva appeared before him in an androgynous form, Brahmā realized his omission and created females. Yet another legend has it that the sage (ṛṣi) Bhṛṅgi had vowed to worship only one deity and so failed to circumambulate and to prostrate himself before Pārvatī. Pārvatī tried to force him to do so by asking to be united with her lord, but the sage assumed the form of a beetle and continued to circumambulate only the male half, whereupon Pārvatī became reconciled and blessed Bhṛṅgi.

Ārdhas (Europe): *see* Arda River.

Ardmore, city, seat (1907) of Carter county, southern Oklahoma, U.S., north of the Red River, near Lake Texoma and the Texas state line. Founded in 1887 in Chickasaw Indian Territory after the arrival of the Santa Fe Railway, the town was named for the Philadelphia, Pa., suburb that was the home of a Santa Fe official. It developed as the business centre of a large cattle and farming region and grew rapidly after the discovery of oil nearby in 1905.

Oil refining, manufacturing, ranching, tourism, and wholesaling are the major economic activities of the city. Ardmore is the site of Carter Seminary for Chickasaw Indian Girls (formerly Hargrove College; Methodist, founded 1895). Lake Murray State Park and the Chickasaw National Recreation Area (embracing Arbuckle Mountains) are nearby. Inc. 1898. Pop. (1990) 23,079.

Consult the INDEX first

Ards, Irish AN AIRD, district, Northern Ireland. Formerly within County Down, in 1973 Ards was established as a district with an area of 139 sq mi (361 sq km). It extends northward from just south of the village of Killinchy along the western shoreline of Strangford Lough (inlet of the sea) to the town of Newtownards and encompasses the peninsula of land east of Strangford Lough. Bordered by North Down and Castlereagh districts to the northwest and Down district to the southwest, Ards is composed of relatively dry, rolling lowlands in the west; the peninsula is characterized by clusters of drumlins (oval mounds of glacial till). Newtownards,

settled about 1608 by Scots of the Montgomery clan at the site of a Dominican friary (now in ruins), is the district's administrative seat and manufacturing centre, with textile, metal, and engineering industries. Much of the district's land is devoted to crops (potatoes and barley) and pastureland. Donaghadee, at the northeastern end of the peninsula, is a popular resort town, and bird sanctuaries are found along the lough-side. Roads extending throughout the district merge with a national highway at Newtownards, then run westward to Belfast. Pop. (2001) 73,244.

Arduino, Giovanni (b. Oct. 16, 1714, Capri-Veronese, Veneto, republic of Venice [Italy]—d. March 21, 1795, Venice), the father of Italian geology, who established bases for stratigraphic chronology by classifying the four main layers of the Earth's crust as Primary, Secondary, Tertiary, and Quaternary.

From an early age, Arduino showed an interest in mining, establishing a reputation throughout northern Italy as a mining expert, and in 1769 the republic of Venice named him director of agriculture and industry. With occasional help from his brother Pietro (1728–1805), a botanist at the University of Padua, Arduino supervised such enterprises as land reclamation, livestock raising, and the construction of improved agricultural equipment. He also did research in mining, metallurgy, and chemistry for the republic.

In the early 1760s Arduino identified four distinct major geologic strata composed of numerous fossil-filled minor strata. He also recognized the significance of the fossil layers and pioneered the use of fossils and chemical methods to determine the age of rock formations.

are, basic metric unit of area measure, equal to 100 square metres. Its multiple, the hectare (*q.v.*: 100 ares), has become the principal unit of land measurement in common use.

area, culture: *see* culture area.

areca nut: *see* betel.

Arecales, order of flowering plants that contains only one family, the palms (Palmae). About 2,800 species are known. *See* palm.

Arecibo, municipality, northern Puerto Rico. It lies on a small inlet near the mouth of the Arecibo River. One of the oldest municipalities in the commonwealth, it was authorized in 1537 by the Spanish crown and settled in 1556. In 1616 it was chartered as a town, and in 1778 it received the royal title *villa*. An official U.S. port of entry, Arecibo has Puerto Rico's largest rum distilleries and produces agricultural machinery, clothing, paper, plastics, and sporting goods; it is linked by rail to San Juan. Arecibo has a regional college of the University of Puerto Rico. South of Arecibo is one of the world's most powerful radar-radio telescopes, a 300-metre (1,000-foot) installation used for astronomical research. Pop. (2004 est.) 102,117.

Arecibo Observatory, astronomical observatory located 16 km (10 miles) south of the town of Arecibo in Puerto Rico; it is the site of the world's largest single-unit radio telescope. This instrument, built in the early 1960s, employs a 300-metre (1,000-foot) spherical reflector consisting of perforated aluminum panels that focus incoming radio waves on movable antenna structures positioned about 168 metres (550 feet) above the reflector surface. The antenna structures can be moved in any direction, making it possible to track a celestial object in different regions of the sky. The observatory also has an auxiliary 30-metre telescope that serves as a radio interferometer and a high-power transmitting facility used to study the Earth's atmosphere.

The Arecibo Observatory has produced detailed radar maps of the surface of Venus

and precise information about that planet's rotation. The observatory also has made such contributions to radio astronomy as the detection of neutron star matter in pulsars.

Arecibo River, Spanish in full RÍO GRANDE DE ARECIBO, river in west-central Puerto Rico. The Arecibo River rises in the Cordillera Central just east of Mount Guilarte. It flows north-northeast about 40 miles (65 km) through a coffee-growing region and descends across the northern coastal plain to empty into the Atlantic Ocean just east of the port of Arecibo. At the northern edge of the cordilleran foothills, the river is impounded by the Dos Bocas hydroelectric dam and reservoir system (1943), which is linked to the even larger Caonillas hydroelectric dam and reservoir upstream on the Caonillas River, a tributary of the Arecibo.

Arecidae, subclass of herbaceous monocotyledonous shrubs, vines, and trees. A brief treatment of the Arecidae follows. For full treatment, *see* MACROPAEDIA: Angiosperms.

The four orders within the subclass—Areciales, Cyclanthales, Pandanales, and Arales—together contain five families and about 5,600 species. Most members are found in the order Arecales, which contains the lone family Arecaceae (palms). The flowers in the subclass are small and are arranged in tight inflorescences, often in the form of a spadix subtended by a spathe. The perianth, which is often small, is arranged in two series of two or three tepals. The stamens are an obvious feature of the group. The leaves are organized either at the base of the plant or in a terminal crown.

Arena Chapel, also called SCROVEGNI CHAPEL (consecrated March 25, 1305), small chapel built in the first years of the 14th century in Padua, Italy, by Enrico Scrovegni and containing frescoes by the Florentine painter Giotto. A "Last Judgment" covers the entire west wall. The rest of the chapel is covered with frescoes in three tiers representing scenes from the lives of Saints Joachim and Anna, the life of the Virgin, the Annunciation, and the Life and Passion of Christ, concluding with Pentecost. Below the three narrative bands is a fourth containing monochrome personifications of the virtues and vices. The frescoes were completed in or before 1309, and they are generally dated about 1305–06.

Arend-Roland, Comet, comet remarkable for its anomalous second tail, which projects toward rather than away from the Sun. It was discovered on the night of Nov. 8–9, 1956, by S. Arend and P. Roland in Belgium. Its perihelion passage (*i.e.*, its closest approach to the Sun) occurred on April 20, 1957. Because it was discovered months before perihelion, lengthy observations could be carried out. The anomalous tail appeared for a few nights late in April, changing direction from night to night and appearing as a sharp spike aimed at the Sun. This was an effect of perspective, of viewing edgewise a fan of debris from the comet, scattered ahead of it along its orbit.

Arendt, Hannah (b. Oct. 14, 1906, Hannover, Ger.—d. Dec. 4, 1975, New York, N.Y., U.S.), German-born American political scientist and philosopher known for her critical writing on Jewish affairs and her study of totalitarianism.

Arendt attended the universities of Marburg, Freiburg, and Heidelberg (from which she received her Ph.D. in 1928). At Marburg she began a romantic relationship with her teacher, Martin Heidegger. In 1933, when Heidegger joined the Nazi Party and began implementing Nazi educational policies as rector of Freiburg, Arendt, who was Jewish, was forced to flee to Paris. She married Heinrich Blücher, a philosophy professor, in 1940. She again became a fugitive from the Nazis in 1941, when she and her husband immigrated to the United States.

Settling in New York City, she became research director of the Conference on Jewish Relations (1944–46), chief editor of Schocken Books (1946–48), and executive director (1949–52) of Jewish Cultural Reconstruction, Inc., which sought to salvage Jewish writings dispersed by the Nazis. She became a U.S. citizen in 1951.

In her monumental *Origins of Totalitarianism* (1951), Arendt related the development of totalitarianism to 19th-century anti-Semitism and imperialism and saw its growth as the outcome of the disintegration of the traditional nation-state. Totalitarian regimes, she argued, because of their pursuit of raw political power and neglect of material or utilitarian considerations, had revolutionized the social structure and made contemporary politics nearly unpredictable. That work established her as a major political thinker. She served on the faculty of the University of Chicago (1963–67) and thereafter at the New School for Social Research, New York City.

In the controversial book *Eichmann in Jerusalem* (1963), based on her reportage of the trial of Adolf Eichmann in 1961, Arendt argued that Eichmann's crimes resulted not from a wicked or depraved character but from "thoughtlessness": he was simply an ambitious bureaucrat who failed to reflect on the enormity of what he was doing. His role in the mass extermination of Jews epitomized "the fearsome, word-and-thought-defying banality of evil" that had spread across Europe. Arendt's refusal to recognize Eichmann as "inwardly" evil prompted fierce denunciations from both Jewish and non-Jewish intellectuals.

Arendt resumed contact with Heidegger in 1950, and she subsequently defended him by claiming that his Nazi involvement had been the "mistake" of a great philosopher. In the late 20th century, some scholars suggested that Arendt's personal and intellectual attachment to her former teacher had led her to adopt a lenient assessment of him that was inconsistent with her condemnation of the collaboration of others and with her insistence in various writings that any act of compromise with evil is wholly immoral.

Among Arendt's other works are *The Human Condition* (1958), *Between Past and Future* (1961), *On Revolution* (1963), *Men in Dark Times* (1968), *On Violence* (1970), and *Crises of the Republic* (1972). Her unfinished manuscript *The Life of the Mind* was published in 1978. *Responsibility and Judgment*, published in 2003, collects essays and lectures on moral topics from the years following publication of *Eichmann in Jerusalem*.

Arenig Series, also called ARENIGIAN SERIES, the second of six divisions (in ascending order) constituting the Ordovician System, representing all those rocks deposited worldwide during the Arenigian Age (488 to 478 million years ago). The series' name is derived from the Arenig mountains in Gwynedd county in North Wales, which serve as the type area in Great Britain for rocks of this age. Welsh rock strata belonging to the series attain a thickness of about 1,200 m (4,000 feet) and are not rich in fossils. One possible alternative global stratotype section is found in western Newfoundland, but a global stratotype section and point (GSSP) has not yet been formally proposed by the International Commission on Stratigraphy. The base of the fossil zone of the graptolite species *Tetragraptus approximatus* is widely accepted as closely approximating the base of the Arenig Series in Britain. This level also corresponds to the base of the fossil zone of the conodont *Paroistodus proteus*. The Arenig Series is overlain by the Llanvirn Series.

arenite, any sedimentary rock that consists of sand-sized particles (0.06–2 millimetres

[0.0024–0.08 inch] in diameter), irrespective of composition. More formal nomenclature of such rocks is based on composition, particle size, and mode of origin—e.g., sandstone, arkose, quartzite, graywacke, and subgraywacke.

Arensky, Anton (Stepanovich) (b. June 30 [July 12, New Style], 1861, Novgorod, Russia—d. Feb. 12 [Feb. 25], 1906, Terijoki, Finland, Russian Empire), Russian composer known especially for his chamber music.

Arensky
Novosti Press Agency

Though a composition student of Nikolay Rimsky-Korsakov, Arensky's work was more akin to that of Peter Ilich Tchaikovsky; the predominant moods of his music are lyrical and elegiac. Of his three operas only the first, *A Dream on the Volga* (Moscow, 1891), was successful. His *Piano Trio in D Minor* and *String Quartet in A Minor* show him at his best. His piano pieces, which exceed 100 in number, include four suites for two pianos. Besides conducting in Moscow, he held teaching posts at the Moscow Conservatory (1882–95) and the directorship of the imperial chapel at St. Petersburg (1895–1901).

Areopagus, earliest aristocratic council of ancient Athens. The name was taken from the Areopagus ("Ares' Hill"), a low hill northwest of the Acropolis, which was its meeting place.

The Areopagite Council probably began as the king's advisers. Early in the Archaic period it exercised a general and ill-defined authority until the publication of Draco's Code of Law (c. 621). Membership continued for life and was secured by having served as archon, an office limited to the eupatrids (Greek: *eupatridai*, "nobles by birth"). Under Solon (archon 594 BC), the composition and authority of the council were materially altered when the archonship was opened to all with certain property qualifications, and a Boule, a rival council of 400, was set up. The Areopagus nevertheless retained "guardianship of the laws" (perhaps a legislative veto); it tried prosecutions under the law of *eisangelia* ("impeachment") for unconstitutional acts. As a court under the presidency of the *archōn basileus*, it also decided cases of murder.

For about 200 years, from the middle of the 6th century BC, the prestige of the Areopagus fluctuated. The fall of the Peisistratids, who during their tyranny (546–510) had filled the archonships with their adherents, left the Areopagus full of their nominees and thus in low esteem; its reputation was restored by its patriotic posture during the Persian invasion. In 462 the reformer Ephialtes deprived the Areopagus of virtually all its powers save jurisdiction on homicide (c. 462). From the middle of the 4th century BC, its prestige revived once again, and by the period of Roman domination in Greece it was again discharging significant administrative, religious, and educational functions.

Arequipa, *departamento* (formed 1822) and *región*, southern Peru, bounded to the southwest by the Pacific Ocean. Its arid coastal and montane landscapes are cut intermittently by streams flowing from glaciers in the Andes Mountains. Irrigated coastal crops include cotton, rice, sugarcane, and olives. Corn (maize), potatoes, leeks, hot peppers, and asparagus are cultivated in the uplands, which are also important for livestock grazing. Gold, silver, and copper are among the leading exports, as are garments of alpaca wool. Matarani and Mollendo are major coastal ports; Ilo, in neighbouring José Carlos Mariátegui *región*, handles most of the mineral exports. The city of Arequipa, the capital, is in the mountains. There are rail and road links with the ports and with the inland cities of Cuzco and Puno. The Pan-American Highway provides access to Lima (the national capital) and Chile. Arequipa *región*, coextensive with the *departamento*, was nominally established in 1987. Area 24,458 square miles (63,345 square km). Pop. (2000 est.) 1,072,958.

Arequipa, city, capital of Arequipa *departamento* and *región*, southern Peru, in the Chili River valley of the Andes Mountains. It lies at more than 7,550 feet (2,300 m) above sea level, at the foot of the dormant cone of Misti Volcano, which reaches an elevation of 19,098 feet (5,821 m). Flanking Misti are Mounts Chachani and Pichupichu. Earthquakes have damaged the city several times, notably in 1600, 1868, 1958, 1979, and 2001. The air is dry and the climate pleasant, with an annual average temperature of 58° F (14° C) and annual precipitation of about 4 inches (100 mm).

Under the Inca empire Arequipa was an important point on the route from Cuzco to the seacoast. The city was refounded in 1540 on orders from the conquistador Francisco Pizarro to establish a stronghold in the region, under the name Nuestra Señora de la Asunción del Valle Hermoso ("Our Lady of the Assumption of the Beautiful Valley").

Arequipa has earned the sobriquet Ciudad Blanca ("White City") because sillar, a local white volcanic stone, is used in many of its buildings. The seat of an archbishopric, Arequipa has a cathedral (founded 1612; rebuilt c. 1845 and 1868) and several churches dating from the Spanish colonial period, including San Francisco (1552), San Agustín (1574), and La Compañía (1595), with its renowned Plateresque facades. Among the city's educational centres are the National University of San Agustín (1828) and the Catholic University of Santa María (1961). The historic city centre, which was designated a UNESCO World Heritage site in 2000, was damaged by a powerful earthquake the following year.

Arequipa has diversified industries and is a major processing centre for alpaca, llama, and sheep's wool. It is the commercial, political, and military centre of southern Peru, easily accessible by air, rail, and highway. Arequipa is also a popular tourist centre, with bathing resorts, hot springs, and Inca remains in the vicinity. The fertile soils of the surrounding district produce a variety of crops. Arequipa, with Peru's second largest metropolitan population (after Lima-Callao), has grown markedly since the 1960s, largely through in-migration. Pop. (1998 est.) 710,103.

Arequipa, Volcán de (Peru): see Misti Volcano.

Ares, in Greek religion, god of war or, more properly, the spirit of battle. Unlike his Roman counterpart, Mars (*q.v.*), he was never very popular, and his worship was not extensive in Greece. He represented the distasteful aspects of brutal warfare and slaughter. From at least the time of Homer, who established him as the son of the chief god, Zeus, and Hera, his consort, Ares was one of the Olympian deities; his fellow gods and even his

parents, however, were not fond of him (*Iliad* v, 889 ff.). Nonetheless, he was accompanied in battle, by his sister Eris (Strife) and his sons (by Aphrodite) Phobos and Deimos (Panic and Rout). Also associated with him were two lesser war deities: Enyalios, who is virtually identical with Ares himself, and Enyo, a female counterpart.

Ares' worship was largely in the northern areas of Greece, and, although devoid of the social, moral, and theological associations usual with major deities, his cult had many interesting local features. At Sparta, in early times, at least, human sacrifices were made to him from among the prisoners of war. At Sparta also a nocturnal offering of dogs—an unusual sacrificial victim, which might indicate a chthonic (infernal) deity—was made to him as Enyalios. During his festival at Geronthrae in Laconia, no women were allowed in the sacred grove, but at Tegea he was honoured in a special women's sacrifice as Gynaikothoinas ("Entertainer of Women"). At Athens he had a temple at the foot of the Areopagus ("Ares' Hill").

The mythology surrounding the figure of Ares is not extensive. He was associated with Aphrodite from earliest times; in fact, Aphrodite was known locally (e.g., at Sparta) as a war goddess, apparently an early facet of her character. Occasionally, Aphrodite was

Ares, classical sculpture; in the National Roman Museum, Rome
Anderson—Alinan from Art Resource

Ares' legitimate wife, and by her he fathered Deimos, Phobos, and Harmonia. By Aglauros, the daughter of Cecrops, he was the father of Alcippe. He was the sire of at least two of Hercules' adversaries: Cycnus and Diomedes of Thrace. On vases, Ares is usually the typical armed warrior. The Parthenon frieze contains a group of Olympians, among whom Ares, in unwarlike garb, has been tentatively identified. He also appears on the great frieze of the altar at Pergamum.

the INDEX
first

Aretaeus OF CAPPADOCIA (fl. 2nd century AD), Greek physician from Cappadocia who practiced in Rome and Alexandria, led a revival of Hippocrates' teachings, and is thought to have ranked second only to the father of medicine himself in the application of keen observation and ethics to the art. In principle he adhered to the pneumatic school of medicine, which believed that health was maintained by "vital air," or *pneuma*. Pneumatists felt that

an imbalance of the four humours—blood, phlegm, cholera (yellow bile), and melancholy (black bile)—disturbed the *pneuma*, a condition indicated by an abnormal pulse. In practice, however, Aretaeus was an eclectic physician, since he utilized the methods of several different schools.

After his death he was entirely forgotten until 1554, when two of his manuscripts, *On the Causes and Indications of Acute and Chronic Diseases* (4 vol.) and *On the Treatment of Acute and Chronic Diseases* (4 vol.), both written in the Ionic Greek dialect, were discovered. These works not only include model descriptions of pleurisy, diphtheria, tetanus, pneumonia, asthma, and epilepsy but also show that he was the first to distinguish between spinal and cerebral paralyses. He gave diabetes its name (from the Greek word for "siphon," indicative of the diabetic's intense thirst and excessive emission of fluids) and rendered the earliest clear account of that disease now known.

arête (French: "ridge"), in geology, a sharp-crested serrate ridge separating the heads of opposing valleys (cirques) that formerly were occupied by Alpine glaciers. It has steep sides formed by the collapse of unsupported rock, undercut by continual freezing and thawing (glacial sapping; see cirque). Two opposing glaciers meeting at an arête will carve a low, smooth gap, or col. An arête may culminate in a high triangular peak or horn (such as the Matterhorn) formed by three or more glaciers eroding toward each other.

Arethusa, in Greek mythology, a nymph who gave her name to a spring in Elis and to another on the island of Ortygia, near Syracuse.

The river god Alpheus fell in love with Arethusa, who was in the retinue of Artemis. Arethusa fled to Ortygia, where she was

Arethusa on a silver coin from the workshop of Euainetos, c. 413 bc; in the National Archaeological Museum, Syracuse, Sicily
Konrad Helbig

changed into a spring. Alpheus, however, made his way beneath the sea and united his waters with those of the spring. According to Ovid's *Metamorphoses*, Arethusa, while bathing in the Alpheus River, was seen and pursued by the river god in human form. Artemis changed her into a spring that, flowing underground, emerged at Ortygia.

In an earlier form of the legend, it was Artemis, not Arethusa, who was the object of the river god's affections and who escaped by smearing her face with mire, so that he failed to recognize her. The story probably originated from the fact that Artemis Alpheiaia was worshipped in both Elis and Ortygia and also that the Alpheus in its upper part runs underground.

Aretino, Leonardo: see Bruni, Leonardo.

Aretino, Pietro (b. April 20, 1492, Arezzo, Republic of Florence [Italy]—d. Oct. 21, 1556, Venice), Italian poet, prose writer, and dramatist celebrated throughout Europe in his time for his bold and insolent literary attacks on the powerful. His fiery letters and dialogues are of great biographical and topical interest.

Aretino, detail of an oil painting by Titian, in the Frick Collection, New York

© the Frick Collection, New York

Although Aretino was the son of an Arezzo shoemaker, he later pretended to be the bastard son of a nobleman and derived his adopted name ("the Aretine") from that of his native city (his real name is unknown). While still very young, he went to Perugia and painted for a time and then moved on to Rome in 1517, where he wrote a series of viciously satirical lampoons supporting the candidacy of Giulio de' Medici for the papacy (Giulio became Pope Clement VII in 1523). Despite the support of the pope and another patron, Aretino was finally forced to leave Rome because of his general notoriety and his 1524 collection of *Sonetti lussuriosi* ("Lewd Sonnets"). From Rome he went to Venice (1527), where he became the object of great adulation and lived in a grand and dissolute style for the rest of his life.

One of Aretino's closest friends in Venice was the painter Titian, for whom he sold many paintings to Francis I, king of France: a great gold chain that Aretino wears in Titian's portrait (c. 1545; Pitti Palace, Florence) was a gift from the king.

Among Aretino's many works, the most characteristic are his satirical attacks, often amounting to blackmail, on the powerful. He grew wealthy on gifts from kings and nobles who feared his satire and coveted the fame accruing from his adulation. His six volumes of letters (published 1537–57) show his power and cynicism and give ample justification for the name he gave himself, "*flagello dei principi*" ("scourge of princes"). Aretino was particularly vicious in his attacks on Romans because they had forced him to flee to Venice. In his *Ragionamenti* (1534–36; modern edition, 1914; "Discussions"), Roman prostitutes reveal to each other the moral failings of many important men of their city, and in *I dialoghi* and other dialogues he continues the examination of carnality and corruption among Romans.

Only Aretino's dramas were relatively free of such venomous assaults. His five comedies are acutely perceived pictures of lower-class life, free from the conventions that burdened other contemporary dramas. Of the five comedies, written between 1525 and 1544 (modern collection, *Commedie*, 1914), the best known is *Cortigiana* (published 1534, first performed 1537, "The Courtesan"), a lively and amusing panorama of the life of the lower classes in papal Rome. Aretino also wrote a tragedy, *Orazia* (published 1546; "The Horatii"), which has been judged by some the best Italian tragedy written in the 16th century.

BIBLIOGRAPHY. Biographies include Thomas Caldecot Chubb, *Aretino, Scourge of Princes* (1940); and James Cleugh, *The Divine Aretino, Pietro of Arezzo, 1492–1556* (1965).

Arevaci, a Celtiberian tribe, formed by the mingling of Iberians and migrating Celts in

the 6th century bc, who inhabited an area near Numantia and Uxama in what is now Spain. The Celtiberians excelled at horsemanship, fighting, and metalworking. They wore sewn garments made of woven and dyed cloth.

The Arevaci and the Belli rose up against the Romans in the Celtiberian War, which lasted from 153 to 133 bc. After such victories as that of 137 bc, in which 20,000 Romans surrendered to between 4,000 and 8,000 Celtiberians at Numantia, the tribes' resistance was broken by the Roman siege and destruction of Numantia in 133 bc.

Arévalo (Bermejo), Juan José (b. Sept. 10, 1904, Taxisco, Guat.—d. Oct. 6, 1990, Guatemala City), president of Guatemala (1945–1951), who pursued a nationalistic foreign policy while internally encouraging the labour movement and instituting far-reaching social reforms.

Arévalo was educated at the University of Guatemala and the University of La Plata (1928–34) in Argentina, where he received a doctorate. After serving in the Guatemalan ministry of education in 1936, he returned to Argentina, where he held a variety of academic positions. After a coup d'état (Oct. 20, 1944) overthrew the military dictatorship of Jorge Ubico, Arévalo was elected president in an election in which, for the first time in Guatemalan history, organized labour played an important part. He received 85 percent of the vote. His policies favoured urban and agricultural workers and the nation's Indian population. During his administration a social-security system was established, a labour code enacted, and important programs in education, health, and road building begun. He allowed freedom of speech and of the press and, in accord with his nationalist policy, reopened the dispute over Belize with the British. He was appointed ambassador at large in 1951. During his term in office he refused to recognize Anastasio Somoza's Nicaragua, Francisco Franco's Spain, and Rafael Trujillo's Dominican Republic. In 1963 he was prevented from running for president after Colonel Enrique Peralta seized the government.

Arévalo was the author of a widely circulated book, *The Shark and the Sardines* (1961), which denounced U.S. domination of Latin America. He served as ambassador to France from 1970 to 1972.

Arévalo Martínez, Rafael (b. July 25, 1884, Quezaltenango, Guatemala—d. 1975), Guatemalan novelist and short-story writer whose work is considered one of the most important precursors of modern Spanish-American fiction.

Arévalo Martínez was appointed director of the Guatemalan National Library in 1926, a post he held until 1946. A short-story writer of marked ability, he introduced a new form known as the "psycho-zoological" tale, the most famous of which, "El hombre que parecía un caballo" (1914; "The Man Who Looked Like a Horse"), deals with the conflict between man's spiritual and animal natures. As a novelist, he attempted to explore social problems and problems of the human personality without resorting to realism. He became one of the foremost writers of what has been called fictional magical realism, a form that eventually led to the novel of the absurd. His best-known novels are *Oficina de paz en Orolandia* (1938; "Office of Peace in Orolandia"), *El mundo de los Maharachías* (1938; "The World of the Maharachías"), and *Viaje a Ipanda* (1939; "Voyage to Ipanda"). *Hondura* (1947) is an autobiographical novel.

Arezzo, Latin ARRETIVM, city, capital of Arezzo provincia, Toscana (Tuscany) regione of north-central Italy, in a fertile plain near

the confluence of the Chiana and Arno rivers southeast of Florence. An important Etruscan city, it was known to the Romans as Arretium and was noted for its red-clay Arretine pottery.

San Domenico church, Arezzo, Italy
John Ross—Photo Researchers

A flourishing commune in the Middle Ages, it fell to Florence in 1384 and later became part of the grand duchy of Tuscany. After a short period of French rule during the Napoleonic Wars, the rule of the Habsburg grand dukes was restored until Arezzo became part of Italy in 1861. The city was severely damaged in World War II.

Arezzo's many old churches include the cathedral, begun in 1286 and finally completed in 1914; the Romanesque Santa Maria della Pieve; San Domenico (begun 1275), with a crucifix by Cimabue; the Renaissance Santa Maria delle Grazie, with an altar by Andrea della Robbia; and San Francesco, with a famous series of frescoes, the "Legend of the True Cross," by Piero della Francesca. There are numerous 14th-century palaces and houses around the former city centre, notably the Palazzo della Fraternità. A collection of Arretine vases is housed in the remains of a Roman amphitheatre, and the Etruscan museum and the picture gallery contain fine collections. Arezzo was the birthplace of the writers Petrarch and Pietro Aretino; the artist Spinello Aretino; Guido d'Arezzo, innovator in musical notation; and the painter, architect, and writer Giorgio Vasari.

A centre of road communications, Arezzo has a basic agricultural economy augmented by railroad construction shops and clothing and footwear factories; goldware and lace are exported. Pop. (1987 est.) mun., 91,681.

Arfersiorfik Fjord, fjord in western Greenland, extending east from Davis Strait to the inland icecap. It is 95 miles (152 km) long with a maximum width of 15 miles (24 km). Its arms receive several glaciers, including the Nordenskiöld's. Niaqornaarsuk, a settlement on the northern shore near the fjord's mouth, was the starting point of an expedition in 1883 led by Adolf Erik Nordenskiöld.

Arfon, district, Gwynedd county, northwest Wales. It was created in 1974, covers an area of 158 square miles (409 square km), and extends southward from just north of the village of Aber along the coast of the Menai Strait of the Irish Sea to a point just south of Llandwrog village and eastward to the Snowdonian range. Snowdon, 3,560 feet (1,085 m) above sea level, the highest mountain in England and Wales lies on the district's southeastern border. Arfon borders the districts of Aberconwy to the east and Dwyfor to the south and southwest, with the Menai Strait constituting the western border. The town of Bangor, at the northern entrance to the Menai Strait, became a centre for Celtic Christianity as early as AD 550, when a church, subsequently enlarged to become the town's present cathedral, was founded by St. Deiniol. Many monks fled

there in the early 600s after the massacre at Bangor Is-coed, near Wrexham. Caernarvon, located farther south of Bangor on the Menai Strait, is the site of an enormous castle built by Edward I of England in 1283 to symbolize the strength and splendour of England and as a base from which to subjugate the Welsh. Although the original wooden castle was burned in a revolt, the castle was rebuilt in stone and withstood numerous attacks from Welsh forces led by Owen Glendower, in 1403 and 1404; today it is one of the best-known castles in Britain, having been the scene of royal investitures in 1911 and 1969.

Arfon district gives tourists access to both the Isle of Anglesey and Snowdonia National Park. The town of Llanberis, between two lakes at the entrance to Llanberis pass, is a tourist centre for Snowdonia National Park. The vast Dinorwic slate quarries face Llanberis across the valley, while the once-thriving Bethesda quarries are to the northwest. The slate industry experienced a rapid decline following the introduction of manufactured roof tile, and some light industries have since been established in the area. The town of Bangor is both the administrative seat of the district and a regional cultural centre. Located in Bangor are the University College of North Wales (1884), a group of denominational theological colleges, and a museum of Welsh antiquities. Caernarvon is the seat of Gwynedd county. Arfon district is traversed by highways, and railway service from Chester extends through Bangor to Holyhead on the Isle of Anglesey to provide a rail-ferry sea link between Dublin and London. Pop. (1986 est.) 53,700.

Arfons, Art, byname of ARTHUR EUGENE ARFONS (b. Feb. 3, 1926, Akron, Ohio, U.S.), American automotive racer, three-time holder of the world's land-speed record for wheeled vehicles.

Arfons worked in his father's feed-mill business in Akron, Ohio, before and after service in the U.S. Navy (1943–46), which trained him in diesel mechanics. He began his career as a drag racer in the early 1950s with his brother Walter, with whom he built a series of racing cars, each called the *Green Monster*; and by 1959 he was involved in car racing full time. In the early 1960s he designed the ultimate *Green Monster*, powered by a J-79 jet aircraft engine, which he drove at the Bonneville Salt Flats, Utah. He reached speeds of 434.02 miles per hour (698.34 km/h), Oct. 5, 1964; 536.71 mile/h (863.56 km/h), Oct. 27, 1964; and 576.533 mile/h (927.64 km/h), Nov. 7, 1965. The last of these records was broken eight days later by Craig Breedlove's attainment of a speed of 600.601 mile/h (966.37 km/h).

Arfons also designed speedboats, using the name *Green Monster Cyclops*.

arfvedsonite, amphibole mineral, an iron-rich sodium silicate. Lithium and magnesium replace iron in the structure to form eckermannite. Both minerals characteristically occur as dark-green crystals in alkali igneous rocks and their associated pegmatites. For chemical formula and detailed physical properties, see amphibole (table).

argali (*Ovis ammon*), the largest living wild sheep, found in the highlands of eastern Central Asia. It may stand 1.3 m (4 feet) high at the shoulders and weigh more than 140 kg (300 pounds). Large horns, present in the rams, are especially massive in the Pamir argali, or Marco Polo sheep, in which they may be 1.8 m (6 feet) or more in length.

Argall, Sir Samuel (b. c. 1572, Bristol, Gloucestershire, Eng.—d. c. 1626), English sailor and adventurer who defended British colonists in North America against the French.

Employed by the Virginia Company of London, Argall was commissioned in 1609 to discover a shorter route to Virginia and to

fish for sturgeon. In 1610 he was named admiral of Virginia and commissioned to expel the French from all territory granted to the English by James I. In 1613 he sailed up the Potomac River, searching for corn for the colonists, and abducted the Powhatan Indian princess Pocahontas, whom he held hostage for the return of seven English prisoners. On venturing farther northward along the coast, Argall discovered a new French settlement at St. Sauveur. He destroyed the settlement and took some French prisoners and goods to Jamestown. The council of the Virginia Company then commissioned him to destroy all French settlements south of the 46th parallel, including Port Royal (now Annapolis Royal, Nova Scotia), which he captured in 1614. He returned in that year to England, where he was cleared of charges of wrongdoing in his actions against the French.

Still in the service of the Virginia Company, Argall was elected deputy governor of the province in 1616 and ruled the colony in 1616–19 during the governor's absence. The harshness of his administration led to another inquiry and exonerated. In 1620 he was made captain of a 24-gun merchant vessel in an expedition against Algiers. He became a member of the Council for New England and was knighted in 1622. In 1625, as a member of the King's War Council, Argall commanded a fleet of 28 vessels and conducted an unsuccessful offensive against Cádiz. He died the following year, possibly at sea, but more likely in retirement.

Argand burner, first scientifically constructed oil lamp, patented in 1784 in England by a Swiss, Aimé Argand. The first basic change in lamps in thousands of years, it applied a principle that was later adapted to gas burners. The Argand burner consisted of a cylindrical wick housed between two concentric metal tubes. The inner tube provided a passage through which air rose into the centre to support combustion on the inner surface of the cylindrical flame in addition to that on the outer surface. A glass chimney increased the draft, allowing more complete burning of the oil; an Argand lamp gave about 10 times the light of an earlier lamp of the same size, as well as a cleaner flame, but its oil consumption was greater.

Argand diagram, graphic portrayal of complex numbers, those of the form $a + bi$, in which a and b are real numbers and i is the square root of -1 ; it was devised by the Swiss mathematician Jean Robert Argand in about 1806. One axis represents the pure imaginary numbers (those consisting of the bi portion only); the second represents the real numbers (a values only). This permits the complex numbers to be plotted as points in the field defined by the two axes.

Argead DYNASTY, ruling house of ancient Macedonia from about 700 to about 311 BC; under their leadership the Macedonian kingdom was created and gradually gained predominance throughout Greece. From about 700 the founder of the dynasty, Perdiccas I, led the people who called themselves Macedonians eastward from their home on the Haliacmon (modern Aliákmon) River. Aegae (Edessa) became the capital, and by the reign of Amyntas I (6th century BC) Macedonian power extended eastward beyond the Axios (Axiós) River to dominate the neighbouring Thracian tribes. Amyntas' successor, Alexander I (reigned before 492–c. 450), advanced his frontiers eastward to the Strymon (Struma) River. His byname, "the Philhellene," indicates his efforts to win Greek sympathies. He spread the legend deriving his Argead house from the Temenids of Argos and thus obtained admission to the Olympic Games.

Alexander's son Perdiccas II (reigned c. 450–c. 413) asserted his succession against various brothers and united the Greek cities of Chal-

cidice in a federation centring on the city of Olynthus. Perdiccas' son Archelaus (reigned c. 413–399) adopted a strongly philhellenic policy, introducing Greek artists to his new capital at Pella. He strengthened Macedonia by building roads and fortresses, improving army equipment, and encouraging city life, and his assassination in 399 was followed by seven years of murder and anarchy.

Finally, a great-grandson of Alexander I, Amyntas III, took the throne in 393/392. Although his reign was filled with anarchy and intrigue, he successfully brought unity to Macedonia. His death in 370/369 left three lawful sons, of whom the first two, Alexander II and Perdiccas III, ruled only briefly. In 359 Amyntas' third son, Philip II, assumed control in the name of Perdiccas' infant heir; having restored order he made himself king (reigned 359–336) and raised Macedonia to a predominant position throughout the whole of Greece. Philip's son Alexander III the Great (reigned 336–323) overthrew the Achaemenian Empire and carried Macedonian arms to the Nile and Indus rivers. On Alexander III's death at Babylon his generals divided up the satrapies of his empire. Although Alexander's two successors, his half-brother Philip III Arrhidaeus and his son Alexander IV, furnished a nominal focus for loyalty until about 311, the real power in the empire lay in other hands.

Argelander, Friedrich Wilhelm August (b. March 22, 1799, Memel, East Prussia—d. Feb. 17, 1875, Bonn), German astronomer who established the study of variable stars as an independent branch of astronomy and is

Argelander, detail from an engraving
By courtesy of the Staatsbibliothek, West Berlin

renowned for his great catalog listing the positions and magnitudes of 324,188 stars. He studied at the University of Königsberg, Prussia, where he was a pupil and later the successor of Friedrich Wilhelm Bessel. Argelander was appointed director of the Abo (Turku) Observatory in Finland in 1823 and of the Helsinki Observatory in 1832. In 1837 he published the first major investigation of the Sun's motion through space and in the same year was appointed director of the new observatory in Bonn. In 1844 he began studies of variable stars.

His greatest achievement was the publication of the *Bonner Durchmusterung* (1859–62), which cataloged stars from the north celestial pole to 2° south of the celestial equator. The result of 25 years' labour, the catalog included all stars down to about the ninth magnitude. This work was reissued in 1950.

Argelander founded the *Astronomische Gesellschaft* (Astronomical Society), whose object was to expand his work in collaboration with many observatories.

Argens, Jean-Baptiste de Boyer, marquis d' (marquess of) (b. June 27, 1703, Aix-en-Provence, Fr.—d. Jan. 12, 1771, Toulon), French writer who helped disseminate the skeptical ideas of the Enlightenment by addressing his polemical writings on philosophy, religion, and history to a popular readership. Argens's writings simplified the unortho-

Marquis d'Argens, detail of an engraving by E.-J. Desrochers after a painting by van Pee
Giraudon—Art Resource/EB Inc

dox empirical reasoning of such Philosophes as Pierre Bayle, Bernard de Fontenelle, and Voltaire; the latter considered him an ally.

Of an aristocratic Catholic family, he led a life of dissipation in his youth. He joined the army and then eloped to Spain; at one time he attempted suicide. He spent 25 years in the court of Frederick the Great as chamberlain, producing 18 volumes of letters, *Correspondance philosophique*. As a freethinker, he challenged authoritarian religion and scholasticism, relying on empirical reason and personal ethics. His *Lettres juives* (1738; "Jewish Letters"), *Lettres cabalistiques* (1741; "Cabalistic Letters"), and *Lettres chinoises* (1739–40; "Chinese Letters") are patterned after Montesquieu's *Lettres persanes*.

Argenson, René-Louis de Voyer de Paulmy, marquis d' (b. Oct. 18, 1694, Paris—d. Jan. 26, 1757, Paris), French minister of foreign affairs under King Louis XV

René-Louis, marquis d'Argenson, engraving, 18th century
By courtesy of the Bibliothèque Nationale Paris

from 1744 to 1747. The son of a lawyer, he received legal training and, from 1720 to 1724, served as intendant (royal agent) in Hainaut. As patron of the Club de l'Entresol in Paris, he discussed the political concepts of the Enlightenment with Voltaire and other *philosophes*. In November 1744, several months after France had officially entered the War of the Austrian Succession (1740–48) on the side of Prussia, Argenson was appointed Louis XV's foreign minister. Aspiring to reestablish French hegemony in Europe, he tried unsuccessfully to implement his own doctrinaire schemes for international arbitration. His plans were directed against Spain, Austria, and Russia; but his program was undermined by Louis's own secret diplomacy—about which the minister was not informed—and by court intrigues. By failing to press the diplomatic advantage that resulted from the victory over the Austrians at Fontenoy (May

1745), he left himself open to criticism. In January 1747 he was compelled to resign. As president of the Académie des Inscriptions et Belles-Lettres, Argenson spent the rest of his life in literary pursuits. His *Journal et mémoires* (published 1859–67) forms one of the major sources for the literary and political history of Louis XV's reign.

Argenta, town, Ferrara province, Emilia-Romagna region, northeastern Italy, on the Fiume (river) Reno, southeast of Ferrara city. It has some fine medieval and Renaissance buildings, including the churches of S. Domenico and S. Francesco, and a notable picture gallery. The town was flooded by the German forces during World War II. It is now mainly an agricultural centre. Pop. (1991 prelim.) mun., 22,593.

argentaffin cell, one of the round or partly flattened cells occurring in the lining tissue of the digestive tract and containing granules thought to be of secretory function. These epithelial cells, though common throughout the digestive tract, are most concentrated in the small intestine and appendix. The cells locate randomly within the mucous membrane lining of the intestine and in tubelike depressions in that lining known as the Lieberkühn glands. Their granules contain a chemical called serotonin, which stimulates smooth muscle contractions. Functionally, it is believed that serotonin diffuses out of the argentaffin cells into the walls of the digestive tract, where neurons leading to the muscles are stimulated to produce the wavelike contractions of peristalsis. Peristaltic movements encourage the passage of food substances through the intestinal tract.

Argentan lace, French POINT D'ARGENTAN, lace made at the French town of Argentan from the 17th century, when Louis XIV's minister Jean-Baptiste Colbert founded the lace industry. Characteristic of this lace is a net background consisting of a large hexagonal mesh, the six sides of which are worked over with buttonhole stitching. Flower patterns are similar to those of Alençon, 25 miles away, but are more solid-looking than their Alençon

Argentan lace from Argentan, Fr., mid-18th century; in the Institut Royal du Patrimoine Artistique, Brussels

By courtesy of the Institut Royal du Patrimoine Artistique Brussels photograph © A.C.L. Brussels

counterparts. Argentan lace making declined after the Revolution but was revived briefly in the 1870s.

Argenteau, Florimund Mercy d': see Mercy d'Argenteau, Florimund, Graf von.

Argentera (France-Italy): see Maddalena Pass.

Argenteuil, town, Val-d'Oise *département*, Île-de-France *région*, France. It lies along the north bank of the Seine River, northwest of Paris. Its name comes from silver (*argent*) deposits exploited there by the Gauls. Argenteuil grew up around a convent that was founded in the 7th century and of which Charlemagne's daughter Théorade may have been an early abbess. Héloïse, of the tragic Héloïse-Abelard romance, became the convent's prioress about 1118 but was expelled in 1129, and the convent became a monastery. Enshrined in the monastery's Church of Saint-Denis is the putative seamless robe of Christ, given to the convent by Charlemagne. In the 20th century industrial development and suburban housing almost obliterated the vineyards and asparagus fields that once surrounded Argenteuil. Now many of the industries are gone, replaced by service and commercial activities. Argenteuil's proximity to Paris makes it an important commuter settlement. Pop. (1999) 93,961.

Argentina, village, southeastern Newfoundland, Canada. The village is situated along the west coast of the Avalon Peninsula just to the north of the town of Placentia and overlooks Placentia Bay.

Formerly a herring- and salmon-fishing port known as Little Placentia, it was renamed Argentina (derived from *argentum*, Latin for "silver") when silver was discovered in the vicinity. Most of its inhabitants moved to the nearby community of Freshwater in 1941, when Argentina became the site of the first U.S. lend-lease military base acquired from Great Britain. In August 1941 the Atlantic Charter on the sovereign rights of nations was signed by Franklin D. Roosevelt and Sir Winston Churchill aboard warships anchored offshore; a memorial chapel on the base commemorates the event. The village is a coastal-boat terminus, connected by highway and railroad to St. John's, 81 miles (131 km) east-northeast. Pop. (2001) 450.

Argentièrre, L' (France-Italy): see Maddalena Pass.

Argentina, officially ARGENTINE REPUBLIC, Spanish REPÚBLICA ARGENTINA, country occupying most of the southern portion of South America. The eighth largest country in the world, Argentina is shaped like an inverted triangle with its base at the top; it is some 880 miles (1,420 km) across at its widest from east

Argentina

to west and stretches 2,360 miles (3,800 km) from north to south. Argentina has an undulating Atlantic coastline of some 2,900 miles (4,700 km). It also claims a portion of Antarctica and several islands in the South Atlantic, including the British-ruled Falkland Islands (Islas Malvinas). It is bounded by Chile to the south and west, Bolivia and Paraguay to the north, and Brazil, Uruguay, and the Atlantic Ocean to the east. Buenos Aires is the capital. Area 1,073,399 square miles (2,780,092 square km). Pop. (2003 est.) 36,846,000.

A brief treatment of Argentina follows. For full treatment, see MACROPAEDIA: Argentina.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

The land. Argentina can be divided into at least four major regions: the North, the Andes, the Pampa, and Patagonia. The North is commonly characterized by its two main divisions: The Gran Chaco, or Chaco, made up of dry lowlands between the Andes and the Paraná River, and Mesopotamia, an area between the Paraná and the Uruguay rivers.

The Andean region (commonly divided into the Northwest and the Patagonian Andes) runs along the entire western border of Argentina and contains some of the world's most rugged mountain terrain, with ranges varying in elevation from 16,000 to 22,000 feet (4,900 to 6,700 m). The mountains gradually decrease in size and elevation southward from Bolivia. South America's highest mountain, Aconcagua (22,831 feet [6,959 m]), lies in the northwest, together with a number of other peaks that exceed 21,000 feet (6,400 m).

The Pampa lies to the south and west of the Paraná River and extends to the Atlantic coast between the Río de la Plata in the north and the Colorado River in the south. The region, which was previously a sparsely settled prairie, has become one of the world's most productive agricultural areas. It is also the country's most densely populated region.

Patagonia consists of an Andean zone (also called Western Patagonia) and the main Patagonian plateau south of the Pampa, which extends to the tip of South America. The region provides pastureland for huge herds of sheep. Much of Argentina's extensive reserves of petroleum and natural gas lie in Patagonia. The country's chief coal deposits are also found in southern Patagonia.

Argentina's hydrology is dominated by the rivers that drain into the Río de la Plata. Its basin drains an area of some 6,000,000 square miles (4,100,000 square km), which includes northern Argentina, all of Paraguay, eastern Bolivia, most of Uruguay, and much of Brazil. The river is an estuary formed by the confluence of the Paraná and Uruguay rivers. The system's other tributaries include the Iguazú (Iguaçu), Paraguay, and Pilcomayo.

Argentina lies almost entirely within the temperate zone of the Southern Hemisphere, unlike the rest of the continent to the north, which lies within the tropics. The southern extremes of Argentina also have predominantly temperate conditions, rather than the cold continental climate of comparable latitudes in North America. The temperate climate is interrupted by a long, narrow north-south band of semiarid to arid conditions and by tundra and polar conditions in the high Andes and in southern portions of Tierra del Fuego.

Precipitation is moderate to light in most of the country, with the driest areas in the far northwest and in southern Patagonia. Most rainfall occurs in the northeast, in the Humid Pampa portion of the Pampa, Mesopotamia, and the eastern Chaco.

The people. Argentina's original Indian inhabitants were much reduced in numbers in the centuries after the Spanish first arrived (1516), and by the 19th century the population was largely Spanish in character. A great wave of southern European immigrants began

arriving in the 1880s to work the farms and cattle ranches of the Pampa. Almost half of the European immigrants in the late 19th and early 20th centuries were Italian, and about one-third were Spanish. Many also came from France, Poland, Russia, Germany, and Britain. Spanish is the official language of Argentina. The vast majority of Argentine people are Roman Catholics.

Argentina's population growth was rapid through the first part of the 20th century but declined thereafter as both the birth rate and immigration dropped off. The country's rates of birth and population growth are now among South America's lowest. Life expectancy is about 72 years for males and 79 years for females. Argentina's population density is among the continent's lowest, although areas such as the Humid Pampa, Mesopotamia, and parts of the eastern Northwest are heavily populated. Nine-tenths of the people live in urban areas, about a third in the greater Buenos Aires region alone.

The economy. Argentina has a developed, free-market economy that is based largely on services and manufacturing. Agriculture and ranching, formerly dominant, also continue to be important. The gross national product (GNP), GNP per capita, and value added from manufacturing are among the highest in Latin America. Services constitute some three-fifths of the gross domestic product, and another one-fifth originates from manufacturing. Smaller contributions are made by agriculture, mining, and utilities. Tourism is significant and growing in importance.

Argentina is Latin America's largest exporter of food and other agricultural goods. Wheat is the principal cash crop and is grown mainly in the Pampa. Corn (maize), soybeans, sorghum, sunflower seeds and flax (both grown for oil), fruits and vegetables, and sugarcane are also grown in large quantities. Argentina's vast pasturelands make it a world leader in the production and export of beef and hides from cattle and wool from sheep.

Argentina has extensive forests, but lumbering is confined mostly to the Northwest highlands and to pine and broad-leaved stands in Mesopotamia. A noted Argentine forest product is red quebracho, used to make tannin. Despite Argentina's long coastline, the fish catch is relatively small.

With the exception of petroleum and natural gas, Argentina's exploitable mineral reserves are small and widely scattered. Reserves of iron ore, uranium, lead, zinc, silver, copper, manganese, and tungsten are worked, and materials such as clay, limestone, granite, and marble supply construction needs. Argentina's industries are well served by its abundant energy resources. Petroleum deposits are scattered throughout the country and are particularly rich in east-central Patagonia; the country has become self-sufficient in, and an exporter of, oil. Major rivers are important sources of hydroelectricity, which constitutes a large portion of the country's power production. Thermal plants generate much of the rest. The country is also one of the main producers of nuclear power in Latin America.

Argentina has one of the most highly developed manufacturing sectors of any Latin American country. The processing of beef initiated industrialization early in the 20th century, but increasingly Argentina has tried to break away from its dependence on meat-packing, flour-milling, sugar refining, and other food-processing industries. The national government played a strong role in the diversification process beginning in the 1940s, but by the 1990s efforts were being made to privatize inefficient state-run industries. The country's manufacturing is now well diversified; the principal products include refined petroleum products, portland cement, crude steel, pig and sponge iron, steel tubes, wine, beer, cigarettes, refined sugar, cattle hides, wood pulp, paper,

particleboard, ovens, automobiles, tractors, ovens and stoves, and electrical appliances.

The economy periodically suffered from runaway inflation in the 1970s and '80s. The military government introduced drastic reforms that reduced the rate of inflation, but the Falklands (Malvinas) war of 1982 again caused a sharp rise. It was not until the early and mid-1990s, under civilian rule, that hyperinflation was brought under control. Rising unemployment was another concern of the 1990s.

Argentina's transportation system includes a well-developed railroad system and road network; nearly one-third of the roads are paved. There are some 6,800 miles (11,000 km) of internal waterways on the Paraguay, Paraná, and Uruguay rivers and the Río de la Plata. Argentina has several major seaports, including Buenos Aires, Quequén, Rosario, and Bahía Blanca. There are numerous international airports and permanent-surface airfields.

Argentina's exports consist primarily of cereals; fresh fruits and vegetables; petroleum and petroleum products; animal feed; live animals, meat, and meat products; iron and steel products; and skins, hides, and leather goods. Principal imports consist of machinery and transport equipment, industrial chemicals, and petroleum and petroleum products. Brazil and the United States are the main trading partners of Argentina.

Government and social conditions. Argentina is a federal republic governed under the constitution of 1853, which has been amended many times, often to accommodate military juntas and dictatorships. One such junta ruled Argentina from 1976 until 1983, after which democratic rule was restored.

Executive power is vested in the office of the president, who is elected, with the vice president, to a four-year term. The president may serve for only two consecutive terms but may seek other nonconsecutive terms. The National Congress is a bicameral legislature. The Senate is composed of three representatives from each *provincia* and the Federal Capital, elected for six-year terms. The Chamber of Deputies is apportioned according to population; its members serve four-year terms. The highest judicial body is the Supreme Court; its judges are appointed for life by the president.

Argentina's social-welfare system covers retirement, disability, and survivors' pensions; family allowances; and health insurance. Many of the country's health indicators, such as the proportion of doctors to the total population, are favourable. Argentine cities suffer from a severe housing shortage, caused mostly by the large influx of migrants from the rural areas.

Education in Argentina is free from preschool to the university level and is compulsory for children between the ages of 6 and 14. Virtually the entire population is literate. The University of Buenos Aires (1821) is the country's largest institution of higher education.

The press in Argentina is one of the largest and most sophisticated in Latin America, and some of its dailies, such as *La Prensa* and *La Nación*, both of Buenos Aires, are highly respected internationally. More than two-thirds of the radio and television stations in the country are privately owned. Radio Nacional is the main government-owned radio station.

Cultural life. The traditions of Argentina's various nationalities remain strong, sustained in fairs, fiestas, and regional folklore. The urban population of Argentina boasts a distinctly European influence. Buenos Aires, the national capital, is Argentina's most important cultural centre, with dozens of art galleries and numerous theatres, museums, and concert halls. One of the most prominent cultural institutions in Buenos Aires is the Colón Theatre, a large and beautiful opera house featuring artists from Argentina and abroad.

The tough and resourceful gaucho (ranch hand or cowboy) of the Pampas and Patagonia is a traditional symbol of national character.

History. Little is known of the precolonial history of Argentina. In the south the indigenous Indians were mostly nomadic hunters and fishers; in the northwest, where the Incas had penetrated, they were agriculturists. The Incas had built a highway as far south as what is now the city of Mendoza.

The first Europeans to arrive were the Spanish, but their settlement of Argentina was slow. Buenos Aires, founded in 1536, was abandoned a year later because of attacks from Indians and a lack of fresh water. Subsequent Spanish settlements in Argentina originated from other Spanish colonies in South America, such as those in Chile, Peru, and Paraguay (Asunción), and intermarriage with the Indians was widespread. A simple but vigorous society developed on the basis of Indian labour and the horses, cattle, and sheep imported by the Spaniards, as well as native products such as corn (maize) and potatoes.

Until 1776 Argentina was part of the Viceroyalty of Peru; after 1776 it became part of the newly created Viceroyalty of the Río de la Plata, with Buenos Aires as the capital. This new status, and the exposure to European intellectual and social ideas that resulted, gave Buenos Aires a position of leadership among Spain's colonies in South America.

In 1816 a congress meeting at Tucumán declared the United Provinces of the Río de la Plata to be independent from Spain. A national government was attempted, but several caudillos (regional dictators or strongmen) competed for power, and a brief but destabilizing war was fought with Brazil. In the Pampas, bloody campaigns against nomadic Indians opened up vast tracts of land to ranchers and settlers. In 1829 Juan Manuel de Rosas firmly established himself in the province of Buenos Aires, and by 1835 he had extended his control over the rest of the country. His dictatorship fell in 1852. A constitutional convention was held at Santa Fe, and the new constitution was adopted in 1853. The province of Buenos Aires refused at first to join the union but did so in 1860 after its defeat by the armed forces of other provinces. With the aid of foreign capital and technology, railroads were built; barbed wire, better breeds of cattle and sheep, and the refrigeration of meat were introduced. Argentina became a large-scale exporter of pastoral products to Europe. As commerce grew, so did the revenues of the government, which used them to foster the rising tide of immigration and to establish a public-education system.

In 1880 a period of conservative oligarchical rule, which had as its core the big ranchers, or *estancieros*, began; this gave way in 1916 to a series of moderate, democratically elected governments, but a military coup in 1930 effectively ended this civilian rule. A troubled decade followed, and Juan Perón emerged as a charismatic populist leader in the early 1940s and was elected president in 1946. His policies of encouraging rapid industrial expansion and state intervention in the economy, together with reforms aimed at increasing social benefits for the workers, resulted in lasting economic and social problems. He was ousted by the military and fled the country in 1955. The next 20 years were marked by runaway inflation, strikes, high unemployment, and frequent changes in government.

In 1973 Perón returned from exile and was reelected president. On his death in 1974, he was succeeded by his third wife, who was deposed by military officers in 1976. Amid continuing economic distress, political instability, and mounting terrorist acts by political extremists, a military junta seized power and ruled from 1976 to 1983. During this period the military carried out the notorious "Dirty War," which involved the disappearance (clandestine capture and killing) of at least 10,000 people suspected of subversion. In April 1982 the Argentine armed forces took

possession of the Falkland (Malvinas) Islands, which Argentina had claimed for more than a century. When a British force retook the islands in June, the military junta relinquished its rule in disgrace and permitted a general election in 1983.

Raúl Alfonsín won the presidency and began a program designed to correct the human rights abuses committed by the military governments. Alfonsín also attempted unsuccessfully to reduce the country's high annual inflation rate and its huge foreign debt. More successful was the Peronist Carlos Saúl Menem, who was elected president in 1989 and reelected in 1995 after the constitution had been revised (1994) to permit the president to serve two consecutive terms.

Menem soon faced an economic downturn and charges of corruption against his government. Abroad, Argentina and Chile agreed on the demarcation of their southern borders, and from 1998 relations also improved with Great Britain. A coalition led by Fernando de la Rúa defeated the Peronists in the presidential elections of 1999. At the beginning of the 21st century, Argentina continued to face economic uncertainty.

Argentina, La, byname of ANTONIA MERCÉ Y LUQUE (b. Sept. 4, 1890, Buenos Aires, Arg.—d. July 18, 1936, Bayonne, France), dancer who originated the Neoclassical style of Spanish dancing and helped establish the Spanish dance as a theatrical art.

La Argentina
Dance News

She studied ballet with her parents, both of whom were professional dancers of Spanish birth. At the age of 11 she became premiere danseuse at the Madrid Opera, but she resigned at 14 to study the native dances of Spain. For many years her style was not accepted for concert performance, and her dancing was limited mainly to cafés and music halls. After World War I she was acclaimed in Paris, where she danced at the Moulin Rouge, among other places.

Her first successful solo concert was in 1927 at the Théâtre des Champs-Élysées in Paris, and, from that time until her death, she gave concerts and recitals in Europe, America, and the East, acclaimed as the finest Spanish dancer of the era. Her interpretation of *El amor brujo* (by Manuel de Falla), with its "Ritual Fire Dance" and "Dance of Terror," was one of her most famous creations. Her choreography, derived rather than copied from traditional Hispanic dances, displayed the creative possibilities of Spanish dance. Although

she eventually formed a small company, she is remembered primarily as a master of the solo. Her technique, particularly on the castanets, was outstanding.

argentine, any fish of the family Argentinidae, small, outwardly smeltlike fishes found in deeper waters of the Atlantic and Pacific oceans. The family is usually placed in the order Salmoniformes. Argentines of the species *Argentina silus* are silvery fishes about 45 cm (18 inches) long; they live about 145–545 m (480–1,800 feet) below the surface and are sometimes caught by fishermen.

The true smelts (family Osmeridae) were formerly considered part of the Argentinidae.

Argentine Basin, submarine basin in the floor of the Atlantic Ocean, lying directly east of Argentina. Its deepest sections, the western and southwestern margins, are called the Argentine Abyssal Plain and reach a maximum depth of 20,381 feet (6,212 m). The basin is bounded by the Rio Grande Rise (north), the Mid-Atlantic Ridge (east), the Falkland Rise (south), and the South American continental shelf (west).

Argentine Museum of Natural Sciences, Spanish MUSEO ARGENTINO DE CIENCIAS NATURALES "BERNARDINO RIVADAVIA," national museum (founded 1823) in Buenos Aires. It has zoological, botanical, and geological departments.

The museum has about 2,000,000 exhibits and a library of more than 500,000 volumes. Areas of expertise include archaeology, botany, ecology, entomology, hydrobiology, mineralogy, paleontology, and zoology.

argentite, a silver sulfide mineral (Ag_2S) that is the most important ore of silver. It is abundant, with other silver minerals, in the sulfide mineral deposits of Kongsberg, Nor.; Kremnica, Slovakia; Zacatecas, Mex.; and the Comstock Lode, Nev., U.S.

Argentite, like several other sulfides, selenides, and tellurides of silver and copper, forms isometric crystals at high temperatures, but upon cooling the crystals invert from isometric (cubic) to nonisometric structures while remaining unchanged in external appearance. For example, argentite gives an X-ray pattern identical to that of acanthite, its orthorhombic modification (stable below 91° C, or 196° F). This shows that despite its isometric appearance argentite consists of lamellae of orthorhombic crystals, formed after the overall crystal shape was determined. For detailed physical properties, see sulfide mineral (table).

Argeş, judeţ (district), southern Romania. The Transylvanian Alps (Southern Carpathians) and the sub-Carpathians rise above the settlement areas that are found in intermontane valleys. The district is drained eastward by the Argeş, Cotmeana, and Teleorman rivers. It was formerly included in feudal Walachia. Agricultural activities consist of vineyard and orchard cultivation and livestock raising. Piteşti (*q.v.*), an oil-processing centre, is the district capital. Manufactures of Piteşti and other towns in the district include machinery, textiles, and paper. Coal and lignite are mined north of Mihăieşti, and salt mines, located near Apa Sărată, were worked from the Roman occupation until the 12th century. A hydroelectric dam, measuring 541 feet (165 m) high and 1,007 feet (307 m) long impounds Lake Vidraru. Curtea de Argeş town has a 16th-century church that, according to legend, contained the body of the church architect's wife inhumed in the walls. Cimpulung, a former Roman fortified settlement, has a 13th-century monastery; and Goleşti town is known for a 17th-century manor that was owned by the Goleseu family. A 16th-century sandstone

church and hermitage and the house of the poet George (or Gheorghe) Topîrceanu (1886–1937) are found in Namaeşti. Topoloveni town has a craft cooperative that makes traditional costumes and wood carvings. The 15th-century fortress of Poenari was constructed, overlooking the Argeş River valley, by Vlad Ţepeş, or Vlad the Impaler, a prince known for executing his enemies by impalement, who was the prototype for Count Dracula in Bram Stoker's novel (1897). The fortress has a stairway of 1,400 steps. An arboretum, a forestry experimental station, and a roe deer reserve are found in Mihăieşti; and ancient limestone quarries, designated a natural monument, are located near Albeşti. The road between Piteşti and Cimpulung was a former Roman-Dacian route. Most of the district's railway lines and highways parallel river courses. Area 2,626 square miles (6,801 square km). Pop. (1992 prelim.) 680,600.

Argeş River, river, that rises in the Southern Carpathians, on the southern faces of Moldoveanu and Negoiu peaks in the Făgăraş Range, southern Romania. The river's principal tributaries from the mountains include the Vilsan, Doamnei, and Ţîrgului rivers. It flows southward through Curtea de Argeş and Piteşti, in the sub-Carpathians, and then southeastward across the Danube Plain to enter the Danube near Olteniţa. Its length is 203 miles (327 km), and the area of its basin is 4,850 square miles (12,550 square km). Its major tributary is the Dîmboviţa, which flows through Bucharest on a parallel course. A dam on the Argeş at Căpâşineni creates Lake Vidraru, which is a reservoir for the Gheorghe Gheorghiu-Dej hydroelectric power station.

Arghūn (b. c. 1258—d. March 10, 1291, Bāghcha, Arrān, Iran), fourth Mongol Il-Khan (subordinate *khan*) of Iran (reigned 1284–91). He was the father of the great Maḥmūd Ghāzān (*q.v.*).

Upon the death of his father, Il-Khan Abagha (reigned 1265–82), Prince Arghūn was a candidate for the throne but was forced to yield to a stronger rival, his uncle Tegüder. Arghūn thereafter accused Tegüder's followers of having poisoned his father, protested Tegüder's conversion to Islām, and, by the beginning of 1284, was at the head of a rebellion. After some reverses, he succeeded in overthrowing Tegüder and having him executed (Aug. 10, 1284); Arghūn was formally enthroned the following day and, as an ardent Buddhist, countermanded the Islāmic policies of his predecessor.

In 1289 Arghūn appointed an anti-Islāmic Jew, Sa'd ad-Dawlah, first as his minister of finance and then (in June) as vizier of his entire empire. The predominantly Muslim population may have resented the rule of a Buddhist and a Jew, but their administration proved lawful and just and restored order and prosperity.

In hopes of renewing the war against the Egyptian Mamlūks, Arghūn sought alliances with the Christian West—first, in 1285, writing Pope Honorius IV and then, in 1287, sending emissaries to such leaders as Pope Nicholas IV, Edward I of England, and Philip IV of France. Except for an exchange of letters, however, nothing came of this diplomacy, and the war was not resumed. Arghūn also showed interest in sciences and such pseudo-sciences as alchemy.

While he was dying, fevered and bedridden, in the winter of 1290–91, those factions opposed to Sa'd ad-Dawlah and Arghūn's other favourites rose up and put them to death. After Arghūn's own death, he was succeeded by his brother Gaykhatu (1291–95), his cousin Baydū (1295), and his son Ghāzān (1295–1304).

arginine, an amino acid obtainable by hydrolysis of many common proteins but partic-

ularly abundant in protamines and histones, proteins associated with nucleic acids. First isolated from animal horn (1895), arginine plays an important role in mammals in the synthesis of urea, the principal form in which these species excrete nitrogen. Arginine is one of several nonessential amino acids for adult mammals; *i.e.*, they can synthesize it from glutamic acid and do not require dietary sources.

Argirocastro (Albania): see Gjirokastrë.

Argolis, nomós (department), northeastern Peloponnese, southern Greece. It is a narrow, mountainous peninsula projecting eastward into the Aegean Sea between the Saronic Gulf, (to the northeast) and the Gulf of Argolis (to the southwest). Bordered on the north by Kórinthos (Corinth) and on the west by the mountains of Arcadia, it has been inhabited since Neolithic times. A limestone plateau comprises the highland areas of Argolis, while its lowland plain is alluvial and fertile, though too dry to cultivate without irrigation. The main natural vegetation is macchie, but with cultivation the land supports vegetables, olives, citrus, and grapes. On the coast trees are cultivated for resin. Goats and sheep are raised, especially for milk, which is used in the production of cheese.

The Argolid is an archaeological treasure house and thus a tourist trade centre: Mycenae was the home of Agamemnon, Tiryns the birthplace of Heracles, Epidaurus the home of an ancient healing cult. In ancient times the Gulf of Argolis gave Greece access to trade and exchange of ideas from Crete and Egypt. The city of Argos gave its name to the plain; Nauplia, the chief town of the *nomós*, is a seaport and seaside resort. It was also the first capital of an independent Greece in the 19th century. Area 855 square miles (2,214 square km). Pop. (1991 prelim.) 97,250.

Argolis, Gulf of, Modern Greek ARGOLIKÓS KÓLPOS, deep inlet of the Mirtóön Sea, a western arm of the Aegean, eastern Peloponnese, Greece; it is separated from the Gulf of Saronikós by the Argolis peninsula. Some 30 miles (50 km) long and 20 miles (30 km) wide, it includes some small islands off the eastern shore, notably Psilí and Platiá. At the head of the gulf are its principal port, Nau-

The Greek Gulf of Argolis from the Palomedes fort

plia, and the mouth of the Ínakhos River. Just north of the head of the gulf is Árgos (*q.v.*), an important Mycenaean and Dorian centre continuously occupied since the Early Bronze Age (c. 3500 BC). At the entrance to the gulf is the island of Spétsai, an Athenian summer resort.

argon (Ar), chemical element, inert gas of Group 0 (noble gases) of the periodic table, terrestrially the most abundant and industrially the most frequently used of the noble gases. Colourless, odourless, and tasteless, argon gas was isolated (1894) from air by the British scientists Lord Rayleigh and Sir William Ramsay. Henry Cavendish, while investigating atmospheric nitrogen ("phlogisticated air"), had

concluded in 1785 that not more than $\frac{1}{120}$ part of air might be some inert constituent. His work was forgotten until Lord Rayleigh, more than a century later, found that nitrogen prepared by removing oxygen from air is always about 0.5 percent more dense than nitrogen derived from chemical sources such as ammonia. The heavier gas remaining after both oxygen and nitrogen had been removed from air was the first of the noble gases to be discovered on Earth and was named argon because of its chemical inertness. (Helium had been spectroscopically detected in the Sun in 1868.)

Argon constitutes 1.3 percent of the atmosphere by weight and 0.94 percent by volume and is found occluded in rocks. A major portion of terrestrial argon has been produced, since the Earth's formation, in potassium-containing minerals by decay of the rare, naturally radioactive isotope potassium-40. The gas slowly leaks into the atmosphere from the rocks in which it is still being formed. The production of argon-40 from potassium-40 decay is utilized as a means of determining the Earth's age (potassium-argon dating). On Earth, naturally occurring argon is a mixture of three stable isotopes: argon-36 (0.34 percent), argon-38 (0.06 percent), and argon-40 (99.60 percent).

Argon is isolated on a large scale by the fractional distillation of liquid air. It is used in gas-filled electric light bulbs, radio tubes, and Geiger counters. It also is widely utilized as an inert atmosphere for arc-welding metals, such as aluminum and stainless steel; for the production and fabrication of metals, such as titanium, zirconium, and uranium; and for growing crystals of semiconductors, such as silicon and germanium.

Argon gas condenses to a colourless liquid at -185.8°C (-302.4°F) and to a crystalline solid at -189.4°C (-308.9°F). The gas cannot be liquefied by pressure above a temperature of -122.3°C (-188.1°F), and at this point a pressure of at least 48 atmospheres is required to make it liquefy. At 12°C (53.6°F), 3.94 volumes of argon gas dissolve in 100 volumes of water. An electric discharge through argon at low pressure appears pale red and at high pressure, steely blue.

The outermost (valence) shell of argon has eight electrons, making it exceedingly stable and, thus, chemically inert. Argon atoms do not combine with one another; nor have they been observed to combine chemically with atoms of any other element. Argon atoms have been trapped mechanically in cage-like cavities among molecules of other substances, as in crystals of ice or the organic compound hydroquinone (called argon clathrates).

atomic number	18
atomic weight	39.948
melting point	-189.2°C (-308.6°F)
boiling point	-185.7°C (-302.3°F)
density (1 atm, 0°C)	1.784 g/litre
valence	0
electronic configuration	2-8-8 or $1s^2 2s^2 2p^6 3s^2 3p^6$

Argonaut, in Greek legend, any of a band of 50 heroes who went with Jason (*q.v.*) in the ship *Argo* to fetch the Golden Fleece. Jason's uncle Pelias had usurped the throne of Iolcos in Thessaly, which rightfully belonged to Jason's father, Aeson. Pelias promised to surrender his kingship to Jason if the latter would retrieve the Golden Fleece from Colchis.

The Golden Fleece had originated in the following manner. Jason's uncle Athamas had had two children, Phrixus and Helle, by his first wife, Nephele, the cloud goddess. Ino, his second wife, hated the children of Nephele and persuaded Athamas to sacrifice Phrixus as the only means of alleviating a famine. But before the sacrifice, the shade of Nephele appeared to Phrixus, bringing a ram with a

SCALA—Art Resource

golden fleece on which he and his sister Helle tried to escape over the sea. Helle fell off and was drowned in the strait that after her was called the Hellespont. Phrixus safely reached the other side, and, proceeding to Colchis on the farther shore of the Euxine (Black) Sea, he sacrificed the ram and hung up its fleece in the grove of Ares, where it was guarded by a sleepless dragon.

Jason, having undertaken the quest of the fleece, called upon the noblest heroes of Greece to take part in the expedition. According to the original story, the crew consisted of the chief members of Jason's own race, the Minyans; later, other and better-known heroes, such as Castor and Polydeuces, were added to their number.

The Argonauts arrived at Lemnos, which was occupied only by women, and remained there several months. Proceeding up the Hellespont, they sailed to the country of the Doliones, by whose king, Cyzicus, they were hospitably received. After their departure, however, they were driven back to the same place by a storm and were attacked by the Doliones, who did not recognize them, and in the ensuing battle Jason killed Cyzicus. On reaching the country of the Bebryces, the Argonauts were challenged by the king Amycus, who forced all passing travelers to box with him in the hope of killing them. Polydeuces accepted the challenge and slew him. At the entrance to the Euxine Sea the Argonauts met Phineus, the blind and aged king whose food was constantly polluted by the Harpies. After being freed by the winged sons of Boreas, Phineus told them the course to Colchis and how to pass through the Symplegades, or Cyanean rocks—two cliffs that moved on their bases and crushed whatever sought to pass. Following his advice, Jason sent ahead a dove that was damaged between the rocks, but the *Argo* slipped through while the rocks were rebounding. From that time the rocks became fixed and never closed again.

When the Argonauts finally reached Colchis, they found that the king, Aetes, would not give up the fleece until Jason yoked the king's fire-snorting bulls to a plow and plowed the field of Ares. That accomplished, the field was to be sown with dragon's teeth from which armed men were to spring. Aetes' daughter, the sorceress Medea, who had fallen in love with Jason, gave him a salve that protected him from the bulls' fire and advised him to cast a stone at the newborn warriors to cause them to fight to the death among themselves. After these tasks were accomplished, Aetes

still refused to give over the fleece. Medea, however, put the dragon to sleep, and Jason was able to abscond with the fleece and Medea. Various accounts are given of the homeward course; eventually the *Argo* reached Iolcos and was placed in a grove sacred to Poseidon in the Isthmus of Corinth.

The story of the expedition of the Argonauts was known at least as early as Homer, and the wandering of Odysseus may have been partly founded on it. In ancient times the expedition was regarded as a historical fact, an incident in the opening up of the Black Sea to Greek commerce and colonization.

Argonaut, first submarine to navigate extensively in the open sea, built in 1897 by the American engineer and naval architect Simon Lake. Designed to send out divers rather than to sink ships, the *Argonaut* was fitted with

The Argonaut in dry dock; sketch in McClure's Magazine, 1899, from original photographs by Simon Lake, inventor and builder of the boat

Culver Pictures

wheels for travel on the bottom of the sea and had an airtight chamber with a hatch that could be opened to the sea when the air pressure of the chamber and of the water outside were made equal. In 1898 the *Argonaut* traveled from Norfolk, Va., to New York through heavy storms, proving the seaworthiness of this type of submarine construction.

Argonne, wooded, hilly region in eastern France that forms a natural barrier between Champagne and Lorraine. The Argonne is about 40 miles long and 10 miles wide (65 by 15 km). The hilly massif rarely exceeds 650 feet (200 m) in elevation but is slashed with numerous deep valleys formed by water-courses associated with the Aire and Aisne rivers, which constitute a barrier to transportation. The area has little but strategic importance. It was here the Prussians were repulsed in 1792 by the French at Valmy and where U.S. forces swept over the Germans (Meuse-Argonne Offensive) in 1918.

Argonne National Laboratory, laboratory of the U.S. Department of Energy in Argonne, Ill., that is operated by the University of Chicago and the Argonne Universities Association. It was founded in 1946 to conduct basic atomic research and to develop the peaceful uses of nuclear energy. Argonne National Laboratory now carries out research on a broad range of science and engineering topics, including high-temperature superconductors, advanced computers, and the causes and cures of cancer.

The Argonne laboratory houses several major research facilities, one of the most recent

being the Advanced Photon Source (APS), a 7-GeV synchrotron that is designed to produce intense beams of high-energy X rays. Another facility, ATLAS, is a superconducting linear accelerator that uses beams of heavy ions up to and including uranium. The Intense Pulsed Neutron Source provides a powerful source of neutrons for structural studies. (Ch.Su.)

Argos, Modern Greek *ÁRGOS*, city in the *nomós* (department) of Argolis, northeastern Peloponnese, Greece. It lies just north of the head of the Gulf of Argolis.

The name Argos (adjectival form Argive) apparently signified an agricultural plain and was applied to several districts in ancient Greece. Historically, the Argolis was the easternmost portion of the Peloponnesian peninsula, and the city of Argos was its capital. Agamemnon, Diomedes, and other heroes from Argolis' fertile plain figure prominently in the *Iliad* of Homer. The present town of Argos lies about 4 miles (6.5 km) from the gulf below Kástro hill (ancient Larissa), a site probably occupied since the Early Bronze Age and very prominent in Mycenaean times (c. 1300–1200 BC). A small market town on the Corinth-Náplion rail line, it is built over much of the site of the classical city.

Argos was probably the base of Dorian operations in the Peloponnese (c. 1100–1000 BC), and from that time onward it was the dominant city-state of Argolis. Under the Argive king Pheidon (7th century BC), Argos was the dominant city-state in all the Peloponnese until the rise of Spartan power. The Argives defeated the Spartans at Hysiae (669). In 550 and again in 494, however, Sparta defeated Argos, which took no part in the Greco-Persian Wars. As Spartan power continued to grow, Argos allied with Athens in 461 and again during the Peloponnesian War in 420, but, after the defeat of the Athenian League in 418 and an oligarchic revolution in Argos, the city allied itself with Sparta. Peace with Sparta was broken when Argos united federally with Corinth (392) as the Corinthian War started. Argive loyalty to Corinth soon wavered, and, when Thebes revolted against Sparta (379), democrats took power in Argos and participated in Theban victories over Sparta at Leuctra (371) and Mantinea (362).

Waning Theban power brought renewed Spartan aggression that forced the Argives to appeal to Philip II of Macedonia, who restored to them their old province of Cynuria on the western side of the Gulf of Argolis. After several more incursions, principally Macedonian, into its territory, Argos joined the Achaean League in 229, remaining active except during brief Spartan occupations of the city (225 and 196).

The Roman conquest and the destruction of Corinth (146) increased the importance of Argos, which became the centre of the Achaean League. The city flourished in Byzantine times, but when the Frankish principality of Achaia was established (AD 1204) after the Fourth Crusade with Nauplia as its capital, Argos consequently declined. In 1397 the Turks captured Argos, and again in 1500, massacring the inhabitants and replacing them with Albanians. During the War of Greek Independence (1821–29), the first free Greek Parliament was convened at Argos (1821 and 1829).

Archaeological excavations began on the site—just northeast of the present town, on a rocky spur of Mount Euboea near the ruins of Mycenae—in 1854, and the American School of Classical Studies at Athens began excavations on the Argive Heraeum (Heraion) in

1892 and 1895. The Heraeum had been the centre of the worship of the mother-goddess Hera and the natural sanctuary of the Argolis long before the Dorians came (c. 1100–1000 BC).

After the Dorian invasion a large temple was erected on the Heraeum, probably in the late 7th century BC, but nothing survives of this except the limestone platform and a part of the column-supporting pavement, or stylobate. The Greek geographer Pausanias records the burning of the temple (423 BC) through its priestess's negligence. A more splendid temple was begun by the local architect Eupolemus, designed in limestone with Doric columns. This temple was flanked by impressive stoas, or colonnaded halls.

The French School at Athens conducted various excavations at Argos before and after World War II, uncovering the remains of a temple of Apollo. On the lower ground their researches uncovered another temple site, as well as the site of what was in all probability the Bouleuterion (council house) of the Greek city, city baths and a Heroon (hero-cult shrine) of Roman date, and a cemetery with graves extending from the middle Hellenic period (c. 2000–c. 1600 BC) to late Roman times.

In the early classical period, prominent Argive sculptors included Ageladas and his student Polyclitus, who executed a colossal gold and ivory cult statue of Hera in the temple at the Heraeum, since lost—though some idea of the head may be gained from certain Argive coins of this period. Today, Argos is a prosperous agricultural and commercial centre for vegetables and fruits grown in the plain and for food-processing industries based on them. Pop. (1991) 21,901.

Argostólion, also spelled ARGOSTÓLI, chief port and capital, *nomós* (department) of Cephalonia, which is the largest of the Ionian Islands of Greece. The town is the seat of a bishop of the Greek Orthodox church. It was founded in 1757 by the Venetians when an earthquake destroyed the former capital. The port's well-protected harbour is situated on the eastern prong of a large inlet. The island produces olive oil, wine, currants, and vegetables. Argostólion and its sister port, Sámi, on the east coast were completely devastated by an earthquake in 1953 and were subsequently rebuilt. Pop. (1991) 6,815.

Argovie (Switzerland): *see* Aargau.

Arguedas, Alcides (b. July 15, 1879, La Paz, Bolivia—d. May 8, 1946, Chulumani), Bolivian novelist, journalist, sociologist, historian, and diplomat whose sociological and historical studies and realistic novels were among the first to focus attention on the social and economic problems of the South American Indian.

Arguedas studied sociology in Paris and pursued an active career in government. He represented Bolivia in London, Paris, Colombia, and Venezuela and was a leader of Bolivia's Liberal Party, serving as a national deputy and a senator and becoming minister of agriculture in 1940. Throughout his public career he explored in his own works the plight of the Indians, sympathetically portraying their manners and customs and documenting the social and economic forces that had brought about their exploitation and decline.

Though noted for such sociological studies as *Pueblo enfermo* (1909; "Dying Pueblo") and for his *Historia general de Bolivia* (1922; "General History of Bolivia"), Arguedas is best remembered for his novels about the Indians, especially *Raza de bronce* (1919; "Race of Bronze"), an epic portrayal of the travels of a group of Bolivian Indians, ending with their extermination by white men. His exploration of the Indian problem foreshadowed the Indianist novel of the 1930s and '40s in Latin America.

Arguedas, José María (b. Jan. 18, 1911, Andahuaylas, Peru—d. Nov. 28, 1969, Lima), Peruvian novelist, short-story writer, and ethnologist whose writings capture the contrasts between the white and Indian cultures.

Arguedas was the son of a white traveling judge and a Quechuan Indian. Though his mother died when he was only three years old, Arguedas learned to speak Quechua before he learned Spanish while accompanying his father on his journeys. As a youth he studied Quechua music and customs as well as familiarizing himself with the dominant Spanish culture. All his works reflect the tensions that underlie Peruvian society, in which the Indians, who constitute the majority of the population, are still often considered marginal beings.

Arguedas attended the University of San Marcos in Lima, worked in the post office (1932–37), and taught at the National University in Sicuani (1939–41). After holding a series of administrative positions, he began teaching Peruvian regional cultures at the University of San Marcos in 1959. He also served as the director of the House of Culture (1963–64) and later of the National Museum of History (1964–69).

Agua (1935; "Water"), a collection of three stories, depicts the violent injustices and disorder he saw in the white world as opposed to the peaceful and orderly existence he found in the lives of the exploited but passive Indians. *Yawar fiesta* (1941; "Bloody Feast") treats in detail the ritual of a primitive bullfight symbolizing the social struggle of the Indians and the whites. Arguedas' masterpiece is the novel *Los ríos profundos* (1958; *Deep Rivers*), an autobiographical work that reiterates themes previously treated. The novel *El sexto* (1961; "The Sixth One") is based on Arguedas' imprisonment (1937–38) during Oscar Benavides' dictatorship. *Todas las sangres* ("All the Races") appeared in 1964 and was followed by an unfinished novel, *El zorro de arriba y el zorro de abajo* (1971; "The Fox from Above and the Fox from Below"), the writing of which was prescribed to him by his psychiatrist. It relates the agony of a man completely shattered and disillusioned by life. Arguedas methodically and passionately discusses the events leading to his final day—he committed suicide in a deserted classroom in Lima.

argument, in logic, reasons that support a conclusion, sometimes formulated so that the conclusion is deduced from premises. Erroneous arguments are called fallacies in logic (*see* fallacy). In mathematics, an argument is a variable in the domain of a function and usually appears symbolically in parentheses following the functional symbol.

Argun River, Russian ARGUN, Wade-Giles romanization O-ERH-KU-NA HO, Pinyin ERGUN HE, river rising in the Inner Mongolian autonomous *ch'ü* (region), China, on the western slope of the Greater Khingan Range, where it is known as the Hai-la-erh River. Its length is 1,007 miles (1,620 km), of which about 600 miles (965 km) form the boundary between China and Russia. The confluence of the Argun with the Shilka is regarded as the beginning of the Amur River. The Argun flows for the most part through a wide valley; it has a drainage basin of 63,000 square miles (163,000 square km). In years of abundant rainfall, the Argun overflows into the basin of Hu-lun (Mongol Dalay) Lake in Inner Mongolia. Navigation on the river is irregular.

Argungu, town and traditional emirate, Kebbi state, northwestern Nigeria. The town is on the Sokoto (Kebbi) River and lies at the intersection of roads from Birnin Kebbi, Gwandu, Sokoto town, Augi, and Kaingwa. The town is a collecting point for tobacco, grown in the surrounding riverine floodplains,

and peanuts (groundnuts) and is a major local market centre for rice, millet, sorghum, fish, cotton, cattle, goats, and sheep.

Argungu is noted for its Fashin Ruwa, an annual fishing festival usually held in February, and for its Kanta Museum, which houses 16th-century artifacts. The ruins of the walled town of Surame, the 16th- and 17th-century capital of the Hausa kings of Kebbi, are 35 miles (56 km) east-northeast. In addition to the government school (1919) and Kanta College (1970), Argungu has a health office and a medical centre. Most of its Muslim inhabitants are Kebbawas (a subgroup of the Hausa), but there are clusters of Fulani, Arewa (Ariwa), and Tienga (Kengawa) peoples. The traditional ruling family, the Lekawa, selects the emir, the *sarkin Kebbi*. Pop. (latest est.) town, 26,268.

Argus PANOPTES (Greek: "All Seeing"), figure in Greek legend described variously as the son of Inachus, Agenor, or Arestor or as an aboriginal hero (autochthon). His surname derives from the hundred eyes in his head or all over his body. Argus was appointed by the goddess Hera to watch the cow into which Io (Hera's priestess) had been transformed, but he was slain by Hermes. His eyes were transferred by Hera to the tail of the peacock. This Argus was often confused with the son of Niobe who gave his name to the city of Argos.

Argyll, also called ARGYLLSHIRE, Gaelic EAR-RAGHAIDHEAL ("Coastland of the Gael"), former county, western Scotland, since the reorganization of 1975 largely in Argyll and Bute (*q.v.*) district, of Strathclyde (*q.v.*) region.

In the 2nd century AD Argyll was invaded by Scots (Celts) who came from Ireland, then known as Scotia. The earliest Celtic settlement is assigned to the 3rd century, when a victorious chief, Cairbre Riada, occupied lands in the area later known as Mid Argyll. These lands, called Dalriada, were reinforced from time to time by new bands of immigrants from Celtic Ireland. Dalriada developed gradually as an independent kingdom under ambitious rulers and maintained a separate existence until 843, when one of them, Kenneth I MacAlpin, united the men of Dalriada with the Picts of central Scotland and founded a new hybrid kingdom from which Scotland ultimately emerged. Later, Norsemen obtained control and held sway until 1266, when Argyll was added to the Scottish kingdom. Prior to this, however, semi-independent chiefs of mixed Celtic and Norse ancestry acquired power in Argyll and the Western Isles. One of them, Somerled, really the first lord of the Isles, was killed near Renfrew in 1164 on an expedition against the Scottish king, but the lordship of the Isles was held by his descendants until 1493, when John, the last MacDonald lord of the Isles, was deprived of his vast estates by King James IV. The Campbells of Lochow (now Lochawe) rose on the ruin of the MacDonalds, and their chiefs became earls of Argyll. The combined prominence of the 9 Campbell earls of Argyll in Scottish history and the subsequent 11 dukes of Argyll in the history of Great Britain is perhaps unsurpassed by any other single noble British family.

The failure of the second Jacobite rising (1745), in which the people of Argyll with few exceptions fought for the Hanoverian George II and against the Stuart pretender, was followed by important political and economic changes. The abolition of the heritable jurisdictions in 1747, prior to which Highland lords and chiefs had been petty kings over their tenants and followers, led to the development of new relationships. The rents of tenants became of greater importance to their masters than the former friendly loyalties. Sentimental ties were broken, and the small farms and holdings that had supported large numbers of occupants on a meagre scale of subsistence had to give way to larger farms stocked with flocks

of sheep, immediately but only temporarily more profitable to their owners. Throughout the Highlands, including Argyll, thousands of small tenants were displaced.

In religious history, St. Columba and other Celtic Irish missionaries from Iona spread the Gospel throughout the kingdom of Dalriada in the 6th century. During the first Scottish Reformation (1560), the 5th Earl of Argyll played a prominent part as the most influential Protestant layman in Scotland. In subsequent conflicts between episcopacy and presbyterianism, the latter prevailed and is still the most common form of church government in the Argyll region.

Argyll, EARLS, MARQUESSSES, AND DUKES OF, titled Scottish nobility, in the families Campbell of Lochow and Campbell of Mamore, grouped below chronologically and indicated by the symbol ●.

● **Argyll, Archibald Campbell, 5th Earl of, LORD CAMPBELL, LORD LORNE** (b. c. 1532—d. Sept. 12, 1573), Scottish Protestant who supported Mary, Queen of Scots.

Campbell succeeded his father, Archibald, the 4th earl, in 1558. He was an adherent of John Knox and assisted Lord James Stewart (afterward the regent Moray) in the warfare of the lords of the congregation against the regent Mary of Lorraine, the mother of Mary Stuart. Argyll's support of Mary Stuart after her return to Scotland (1561) gradually separated him from John Knox's party. When Mary escaped from Lochleven Castle in 1568, he commanded her forces during the few days that preceded her flight to England. He then made his peace with Moray, although he may have connived at Moray's murder in 1570. He became lord high chancellor of Scotland in 1572. His first wife was an illegitimate daughter of James V, and he was thus half brother-in-law to Mary and Moray.

● **Argyll, Archibald Campbell, 1st Marquess and 8th Earl of, LORD CAMPBELL, LORD LORNE, LORD OF KINTYRE** (b. 1607?—d. May 27, 1661, Edinburgh, Scot.), leader of Scotland's anti-Royalist party during the English Civil Wars between King Charles I and Parliament. He guided his country to a brief period of independence from political and religious domination by England.

He was the eldest son of Archibald, 7th Earl of Argyll, and took over the management of the family estates in 1619 after his father had renounced Protestantism and become a Roman Catholic. Entering politics as a privy councillor in 1626, Campbell fell out of royal favour in 1637–38 by calling for the abolition of episcopacy in Scotland and by signing the National Covenant pledging to defend Scottish Presbyterianism against Charles I's attempts to impose Anglican forms of worship. As he gained political ascendancy he earned the bitter enmity of James Graham, 5th Earl of Montrose, leader of the Scottish Royalists, whom Campbell consistently managed to outmaneuver. Campbell inherited the earldom of Argyll from his father in 1638, and, as part of Charles I's concession to the Covenanters in 1641, he was created a marquess. He then set about forging an alliance with the Presbyterian-dominated English Parliament.

While his army was occupying northern England for Parliament in 1644, Argyll remained in Scotland to hold Montrose in check. Montrose defeated him at Inverlochy in February 1645 and at Kilsyth in August, but Argyll helped rout the Royalist general in a decisive battle at Philiphaugh on September 13.

In 1648, after the Scottish Royalists had met defeat in their invasion of England, Argyll established a new government at Edinburgh and allied himself with the Parliamentary commander Oliver Cromwell. But the execution of Charles I (Jan. 30, 1649) by Cromwell's Independents horrified the Scots and ruined

the alliance. In desperation, Argyll allowed the Covenanters to invite Charles I's son to Scotland and on Jan. 1, 1651, crowned him King Charles II. The defeat of Charles II in England in September 1651 caused Argyll to submit to Cromwell.

1st Marquess and 8th Earl of Argyll, detail of a portrait after D. Scougall; in the National Portrait Gallery, London
By courtesy of the National Portrait Gallery, London

When Charles finally came to power in England in 1660, following Cromwell's death, he at once arrested Argyll for collaborating with the Commonwealth and had him beheaded at Edinburgh the following year.

BIBLIOGRAPHY. Argyll's career is recounted in John Willcock, *The Great Marquess* (1903).

● **Argyll, Archibald Campbell, 9th Earl of, LORD CAMPBELL, LORNE, AND KINTYRE** (b. Feb. 26, 1629, Dalkeith, Midlothian, Scot.—d. June 30, 1685, Edinburgh), Scottish Protestant leader who was executed for his opposition to the Roman Catholic James II of Great Britain.

In his youth Campbell studied abroad but returned to Scotland in 1649. He fought at Dunbar (Sept. 3, 1650) and, after the Battle of Worcester, joined the Royalist leader Glencairn in the Highlands. Ultimately he fell foul of both the Royalists and their opponents; he was imprisoned in 1657 during the Commonwealth for refusing to renounce allegiance to the Stuarts and again in 1661 for incautious criticisms of the government of Charles II. He was released in 1663, and his father's earldom and lands were restored to him. However, his staunch Protestantism and great territorial influence made him suspect to James, Duke of York (the future James II), who became high commissioner in Scotland in 1680. He was sentenced to death on a dubious charge of high treason in 1681 but escaped to Holland and there joined the conspiracy to procure the succession of the Duke of Monmouth. He led an unsuccessful invasion of Scotland in 1685, was captured at Inchinnan on the River Clyde on June 18, and was beheaded at Edinburgh on June 30.

● **Argyll, Archibald Campbell, 10th Earl and 1st Duke of, MARQUESS OF KINTYRE AND LORNE, EARL OF CAMPBELL AND COWALL, VISCOUNT OF LOCHOW AND GLENYLA, LORD OF INVERARY, MULL, MORVERN, AND TIRIE** (b. 1651?—d. Sept. 25, 1703, Cherton House, near Newcastle-upon-Tyne, Northumberland, Eng.), one of the Scottish leaders of the Revolution of 1688.

Campbell was the eldest son of the 9th earl, and he tried to get his father's attainder reversed by seeking the favour of King James II. Being unsuccessful, however, he went over to The Hague and joined William of Orange as an active promoter of the Revolution of 1688. In spite of the attainder, he was admitted in 1689 to the convention of the Scottish estates as Earl of Argyll, and he was deputed, with Sir James Montgomery and Sir John Dalrym-

ple, to present the crown to William III in its name and to tender him the coronation oath.

In 1690, after the Revolution, an act was passed restoring his title and estates, and it was in connection with the refusal of the Macdonalds of Glencoe to join in the submission to him that he organized a terrible massacre that made his name notorious. In 1696 he was made a lord of the treasury, and his political services were rewarded in 1701 by his being created Duke of Argyll. He had two sons by his wife Elizabeth: John (the 2nd duke) and Archibald (the 3rd duke).

• **Argyll, John Campbell, 2nd Duke of, DUKE OF GREENWICH, MARQUESS OF KINTYRE AND LORNE, EARL OF CAMPBELL AND COWALL, EARL OF GREENWICH, VISCOUNT OF LOCHOW AND GLENYLA, BARON OF CHATHAM, LORD OF INVERARY, MULL, MORVERN, AND TIRIE** (b. Oct. 10, 1678, Petersham, Surrey, Eng.—d. Oct. 4, 1743, Petersham), Scottish supporter of the union with England and commander of the British forces in the Jacobite rebellion of 1715.

The son of the 1st Duke of Argyll (in the Scottish peerage), he actively furthered the union of England and Scotland and was created a peer of England (1705), with the titles Earl of Greenwich and Baron of Chatham. He served under the Duke of Marlborough from 1706 in the War of the Spanish Succession, gaining distinction at the Battle of Malplaquet in 1709. He acted as commander in chief in Spain and as ambassador to the archduke Charles in 1711. Argyll's intervention at Queen Anne's last council meeting helped to ensure the Hanoverian succession (August 1714), and during the early years of George I's reign he stood in high favour at court.

As commander in chief of the forces in north Britain during the Jacobite rebellion of 1715, he managed with very little bloodshed to suppress the rising in Scotland. After a temporary eclipse, caused by disagreement with the ministry rather than the disfavour of the king, he regained his influence and was created Duke of Greenwich (1719). He held various offices and in 1736 was made a field marshal. He strenuously opposed in 1737 the bill to penalize the city of Edinburgh over the Porteous riots, and a violent speech against the government in April 1740 led again to his dismissal from office. Apart from one further short period of power, he spent the remainder of his life in retirement.

• **Argyll, Archibald Campbell, 3rd Duke of, DUKE OF GREENWICH, MARQUESS OF KINTYRE AND LORNE, EARL OF CAMPBELL AND COWALL, EARL OF GREENWICH, VISCOUNT OF LOCHOW AND GLENYLA, BARON OF CHATHAM, EARL AND VISCOUNT OF ILAY, LORD OF INVERARY, MULL, MORVERN, AND TIRIE, LORD ORANSAY, DUNOON, AND ARASE** (b. June 1682, Ham House, Petersham, Surrey, Eng.—d. April 15, 1761, London), brother of the 2nd Duke of Argyll, and a prominent politician during the early Hanoverian period in Britain.

Campbell served in the army for a short time under the Duke of Marlborough, but he was appointed treasurer of Scotland in 1705 and the following year was one of the commissioners for negotiating the union of the two kingdoms, Scotland and England. Raised to the peerage of Scotland as Earl of Ilay, he was among the 16 Scottish peers chosen to sit in the first Parliament of Great Britain. He became a privy councillor in 1711, keeper of the privy seal of Scotland in 1721, and keeper of the Great Seal of Scotland in 1733. He played an important part in the movement led by Duncan Forbes of Culloden to promote Scottish loyalty to the Hanoverians by

raising Highland regiments from among the Whig clans.

Succeeding his brother as duke in 1743, he rebuilt Inveraray castle and collected one of the most valuable private libraries in Great Britain. He died without legitimate issue, and the title descended to his cousin John Campbell, son of John Campbell of Mamore, second son of the 9th Earl of Argyll.

Argyll and Bute, council area, western Scotland, extending from the southwestern Grampian Mountains into the waters of the Atlantic Ocean and North Channel in ragged peninsulas indented and separated by deep-water lochs (sea inlets). Freshwater lochs (lakes) dot the inland areas. It includes many islands of the Inner Hebrides—notably Mull, Islay, and Jura. The council area incorporates most of the historic county of Argyllshire, the islands of Bute and Inchmarnock in the historic county of Buteshire, and the western portion of Dunbartonshire.

The area is part of the wet, deeply dissected northwest Highlands, whose short, vigorous rivers drain westward to the Atlantic Ocean. There is a marked southwest-northeast trend in the structure of the landscape. The mountains, ranging from 1,000 to 3,000 feet (300 to 900 m) in height, have been eroded by ice and water, forming spectacular scenery. Glacial action has sculpted corries, or hillside hollows, created lakes (Lochs Awe and Lomond) and sea lochs (Lochs Fyne and Long), and left deposits of coarse moraines and boulder clay on lower land. The deeply indented, complex coastline of peninsulas and sea lochs has resulted from postglacial drowning. Coastal Argyll and Bute has a cool, damp climate, while inland conditions are much wetter and colder.

Farming, including sheep and cattle raising, remains important to the economy. Less than 5 percent of the total area is under cultivation, mainly oats and hay for fodder. Crofting (small-scale tenant farming) is widespread in the north. Whiskey distilling is important in several places, especially in Campbeltown and on Islay. The estates of the Forestry Commission cover large areas. Industries include the manufacture of chipboard, paper pulp, pit props, and fence posts from local timber. The once-important herring fisheries have declined and have been replaced to some extent by the whitefish. Argyll and Bute includes Finnart, an oil port on Loch Long, and several hydroelectric power stations. Tourism is vital to the economy of Argyll and Bute. Helensburgh, on the River Clyde estuary in the southeast, is a residential suburb of Glasgow and a popular holiday resort. Lochgilphead is the administrative centre. Area 3,110 square miles (8,055 square km). Pop. (1999 est.) 89,730.

argyrodite, heavy, dark sulfosal mineral, a silver and germanium sulfide (Ag_8GeS_6), in which the element germanium was discovered (1886). It is a relatively scarce mineral found in sulfide veins in Germany and in Bolivia. It forms a solid solution series with canfieldite in which tin replaces germanium in the crystal structure, which belongs to the isometric system. For detailed physical properties, see sulfosal (table).

arhat (Sanskrit), Pāli ARAHANT ("one who is worthy"), in Buddhism, a perfected person, one who has gained insight into the true nature of existence and has achieved nirvana (spiritual enlightenment). The arhat, having freed himself from the bonds of desire, will not be reborn again.

The state of an arhat is considered in the Theravāda tradition to be the proper goal of a Buddhist. Four stages of attainment are described in Pāli texts: (1) the state of the "stream-enterer"—i.e., a convert (*sotāpanna*)—achieved by overcoming false beliefs and doubts regarding the Buddha, the teaching (*dhamma*), and the order (*saṅgha*); (2) the

"once-returner" (*sakadāgāmin*), who will be reborn only once again, a state attained by diminishing lust, hatred, and illusion; (3) the "nonreturner" (*anāgāmin*), who, after death, will be reborn in a higher heaven, where he will become an arhat, a state attained by overcoming sensuous desire and ill will, in addition to the attainments of the first two stages; and (4) the arhat. Except under extraordinary circumstances, a man or woman can become an arhat only while living in a monastery.

Mahāyāna Buddhists criticize the arhat ideal on the grounds that the bodhisattva (*q.v.*) is a higher goal of perfection, for the bodhisattva vows to remain within the cycle of rebirths, even though capable of enlightenment, in order to work for the good of others. This divergence of opinion continues to be one of the fundamental differences between the Theravāda and Mahāyāna traditions.

In China, as well as in Korea, Japan, and Tibet, arhats (Chinese: *lohan*; Japanese: *rakan*) were often depicted on the walls of temples in groups of 16 (later enlarged to 18, or even 500). They represent 16 close disciples of the Buddha who were entrusted by him to remain in the world and not to enter nirvana until the coming of the next buddha, in order to provide people with objects of worship.

Århus, amtskommune (county commune), eastern Jutland, Denmark. It was created in 1970 from the former county communes of Århus, Randers, and part of Skanderborg. It extends along Jutland's eastern coast between Mariager and Horsens fjords. The northern part of the county commune is dominated by the Djursland Peninsula, an area of castles and estates, including Rosenholm Castle (home of the Rosenkrantz nobles) and Gammel Estrup, an early 17th-century manor house converted into the Museum of the Jutland Estates. In the southwest, between Silkeborg and Skanderborg, lie the Silkeborg Lake district and the Hill of Heaven. Most of the county commune is fertile lowland forming a prosperous agricultural region. Area 1,761 square miles (4,561 square km). Pop. (1997 est.) 628,725.

Århus, also spelled AARHUS, city, seat of Århus amtskommune (county commune), eastern Jutland, Denmark. It lies along Århus Bay and has an extensive harbour. Its origin is unknown, although traces of a Viking settlement have been found near the outflow of the now-covered Århus stream. The oldest existing charter for the town (1441) refers to a still-earlier charter. Århus became a bishopric in 948 and prospered during the European Middle Ages, having many religious institutions at that time, but the city declined after the Reformation. Beginning in the 19th century, industrialization, the extension of the Danish railway system, and the expansion of its harbour stimulated the city's growth to the point that Århus became Jutland's foremost city and the second largest city in Denmark. It is a busy port and is the centre of commerce and industry in Jutland. Århus' manufactures include metals, chemicals, machinery, beer, and tobacco products, and there are shipbuilding facilities.

Many old buildings can be found in the Old Town section of the city. Medieval landmarks include the 11th-century crypt of St. Nicholas under the Church of Our Lady and the 13th-century Århus Cathedral dedicated to St. Clement, which has a 312-foot- (95-metre-) high tower and is the longest church (305 feet [93 m]) in Denmark. It was built in the Flamboyant Gothic style. The town hall (1938–42) and the university buildings (1933–46) are examples of modern Danish architecture. The Århus Art Museum (1858) includes a display of runic stones, and Den Gamle By is a unique open-air museum (1909) of an early Danish town. The Viking Museum contains exhibits of Viking artifacts. In addition to Aarhus University (opened 1928), there are

Section of the open-air museum "Den Gamle By," Århus, Den.

Toni Schneiders

several specialized colleges and an academy of music in the city. Pop. (1990 est.) 261,437.

Ari THORGISSON THE LEARNED (b. c. 1067—d. Nov. 9, 1148), Icelandic chieftain, priest, and historian whose *Íslendingabók* (*Li-bellus Islandorum; The Book of the Icelanders*) is the first history of Iceland written in the vernacular. Composed before 1133 and covering the period from the settlement of Iceland up to 1120, it includes information on the founding of the Althing (Parliament) and on the settlement of Greenland and Vinland. Ari is also believed to have written much of the original version of *Landnámabók* ("Book of Settlements"), a work listing the genealogies and histories of noble Icelandic settlers. It served as a source for many of the 12th-century "Icelander," or family sagas.

Ari, ha-: see Luria, Isaac ben Solomon.

aria, solo song with instrumental accompaniment, an important element of opera but also found extensively in cantatas and oratorios. The term originated in Italy in the 16th century and first gained currency after 1602, when Giulio Caccini published *Le nuove musiche* (*The New Music*), a collection of solo songs with continuo (usually cello and harpsichord) accompaniment. Caccini called his strophic, or stanza-form, songs *arie* (singular *aria*). Most serious strophic songs published in Italy after 1602 were called arias, and in 1607 the form made its way into opera, in *Orfeo* by Claudio Monteverdi (1567–1643).

Instead of using the same music for every stanza, some composers placed variations of a melody over a repeated, steadily moving bass line. Arias of a popular or frivolous cast were often called canzonetta, or arietta. After about 1620, arias nearly always were composed in triple time (e.g., $\frac{3}{4}$) and also were longer and in new musical forms, often suggested by the texts. By the mid-17th century the leading form had become the da capo aria, in which the initial melody and text were repeated after an intervening melody and text had been sung (i.e., ABA). Often the inner B section was set in duple time (e.g., $\frac{2}{4}$), the outer A sections in triple time (e.g., $\frac{3}{4}$).

During the later 17th and early 18th centuries, the da capo aria was an extremely popular musical form, particularly as a part of Italian operas and cantatas. Aria texts written to the ABA form became shorter in comparison to strophic songs, with only a few lines to each section. The central B section was usually terse and often in a related key, with contrasting mood and tempo. While the story of an opera was advanced through recitative (dialogue sung in quick, speechlike rhythms), the arias, by contrast, were dramatically static,

allowing individual characters to reflect upon the immediately preceding action, after which they perhaps left the stage.

Arias might assume different moods and were classified as *aria cantabile* (lyric aria), *aria di bravura* (virtuoso aria), *aria parlante* (speechlike aria), and so on. These were supposed to be carefully distributed throughout an opera, although such composers as George Frideric Handel and Alessandro Scarlatti did not observe this convention rigidly. The most highly acclaimed singers of the age decorated the reprise of the A section with brilliant improvised embellishments, culminating in an unaccompanied cadenza. The da capo aria was also a staple constituent of cantatas and to a lesser extent of oratorios.

By the late 18th century, a reaction had set in against the da capo form, and it went into sharp decline. Such influential persons as the philosopher Jean-Jacques Rousseau and the composer Christoph Willibald Gluck protested the da capo aria, objecting to its excessive coloratura (or florid singing), to the dramatic impropriety of returning to the mood of section A after the contrasting mood of section B, and to the absurdity often resulting from the repeated section of text.

The aria continued to be prominent in opera after about 1770, but in many different, less stereotyped musical forms, ranging from simple strophic songs to long, elaborate scenes. The operas of Gluck were the first important ones to utilize such a variety of arias. The aria also enjoyed a vogue as a concert piece. Operatic arias (e.g., Leporello's "Catalogue Aria" in W.A. Mozart's *Don Giovanni*) were often written in two parts, one dramatic and one lyrical.

In Italian opera up to *Aida* (1871), the aria was cultivated over a longer period than in German opera. Richard Wagner in his operatic reforms utilized a continuous musical texture in place of separate numbers, using arias only in special instances (e.g., the "Prize Song" in *Die Meistersinger*). In the 20th century, arias occur largely in operas by composers uninfluenced by or hostile to Wagner (e.g., Igor Stravinsky's *Rake's Progress* and the operas of Benjamin Britten). The word aria is occasionally used for instrumental pieces of a songlike nature, as the two middle movements of Stravinsky's *Violin Concerto*.

Ariadne, in Greek mythology, daughter of Pasiphae and the Cretan king Minos. She fell in love with the Athenian hero Theseus and, with a thread or glittering jewels, helped him escape the Labyrinth after he slew the Minotaur, a beast half bull and half man that Minos kept in the Labyrinth. Here the legends diverge: she was abandoned by Theseus and

hanged herself; Theseus carried her to Naxos and left her there to die or to marry the god Dionysus; or she died in childbirth on Cyprus.

Ancient Greek poets and artists liked to portray Ariadne asleep on the shore of Naxos while Dionysus gazes at her with love and admiration. Ariadne's story was later taken up by European artists, writers, and composers,

Ariadne with Dionysus and a satyr, antique bas-relief; in the Vatican Museum

Anderson—Alinari from Art Resource/EB Inc

including Richard Strauss in his opera *Ariadne auf Naxos* (1912; *Ariadne on Naxos*).

Arianism, a Christian heresy first proposed early in the 4th century by the Alexandrian presbyter Arius. It affirmed that Christ is not truly divine but a created being. Arius' basic premise was the uniqueness of God, who is alone self-existent and immutable; the Son, who is not self-existent, cannot be God. Because the Godhead is unique, it cannot be shared or communicated, so the Son cannot be God. Because the Godhead is immutable, the Son, who is mutable, being represented in the Gospels as subject to growth and change, cannot be God. The Son must, therefore, be deemed a creature who has been called into existence out of nothing and has had a beginning. Moreover, the Son can have no direct knowledge of the Father since the Son is finite and of a different order of existence.

According to its opponents, especially the bishop Athanasius, Arius' teaching reduced the Son to a demigod, reintroduced polytheism (since worship of the Son was not abandoned), and undermined the Christian concept of redemption since only he who was truly God could be deemed to have reconciled man to the Godhead.

The controversy seemed to have been brought to an end by the Council of Nicaea (AD 325), which condemned Arius and his teaching and issued a creed to safeguard orthodox Christian belief. This creed states that the Son is *homoousion tō Patri* ("of one substance with the Father"), thus declaring him to be all that the Father is: he is completely divine. In fact, however, this was only the beginning of a long-protracted dispute.

From 325 to 337, when the emperor Constantine died, the Arian leaders, exiled after the Council of Nicaea, tried by intrigue to return to their churches and sees and to banish their enemies. They were partly successful.

From 337 to 350 Constantius, sympathetic to the orthodox Christians, was emperor in the West, and Constantius II, sympathetic to the Arians, was emperor in the East. At a church council held at Antioch (341), an affirmation of faith that omitted the *homoousion* clause was issued. Another church council was held at Sardica (modern Sofia) in 342, but little was achieved by either council.

In 350 Constantius became sole ruler of the empire, and under his leadership the Nicene party (orthodox Christians) was largely crushed. The extreme Arians then declared that the Son was "unlike" (*anómotos*) the Father. These anomoeans succeeded in having their views endorsed at Sirmium in 357, but their extremism stimulated the moderates, who asserted that the Son was "of similar substance" (*homoiousios*) with the Father. Constantius at first supported these homoiousians but soon transferred his support to the homoians, led by Acacius, who affirmed that the Son was "like" (*homoios*) the Father. Their views were approved in 360 at Constantinople, where all previous creeds were rejected, the term *ousia* ("substance," or "stuff") was repudiated, and a statement of faith was issued stating that the Son was "like the Father who begot him."

After Constantius' death (361), the orthodox Christian majority in the West consolidated its position. The persecution of orthodox Christians conducted by the (Arian) emperor Valens (364–378) in the East and the success of the teaching of Basil the Great of Caesarea, Gregory of Nyssa, and Gregory of Nazianzus led the homoiousian majority in the East to realize its fundamental agreement with the Nicene party. When the emperors Gratian (367–383) and Theodosius I (379–395) took up the defense of orthodoxy, Arianism collapsed. In 381 the second ecumenical council met at Constantinople. Arianism was proscribed, and a statement of faith, the Nicene Creed, was approved.

Although this ended the heresy in the empire, Arianism continued among some of the Germanic tribes to the end of the 7th century. In modern times some Unitarians are virtually Arians in that they are unwilling either to reduce Christ to a mere human being or to attribute to him a divine nature identical with that of the Father. The Christology of Jehovah's Witnesses, also, is a form of Arianism; they regard Arius as a forerunner of Charles Taze Russell, the founder of their movement.

Arianism, Semi-: *see* Semi-Arianism.

Ariano Iripino, town, Avellino *provincia*, Campania *regione*, southern Italy. It is situated on a rocky eminence in the Apennines, east of Benevento, in a fertile district that has often been devastated by earthquakes. There is a castle of Norman origin and a 16th-century cathedral in Ariano Iripino. Cave dwellings can still be seen in the vicinity. Cement, pottery, and textiles are manufactured locally, and gypsum mines are nearby. Pop. (1988 est.) mun., 23,312.

Ariaramnes, also spelled *ARIYARAMNA* (fl. late 7th century BC), early Achaemenid king of Persia (reigned c. 640–c. 615).

The son of the previous king, Teispes, Ariaramnes ruled over Persis (modern Fārs, in southwestern Iran); his brother Cyrus I was given control of Anshan in Elam, north of the Persian Gulf. A campaign by the Medes, however, broke the power of Ariaramnes, and he and his son Arsames, who succeeded him, became vassals of Media (in modern northwest Iran). Dating to the reign of Ariaramnes is an important gold tablet written in cuneiform—the first historical inscription in Old Persian from Achaemenid times. The tablet not only traces the royal line of Ariaramnes but also provides the first Persian mention of Ahura Mazda, the supreme god.

Arias (Madrid), Arnulfo (b. Aug. 15, 1901, Penonomé, Panama—d. Aug. 10, 1988, Miami, Fla., U.S.), three times president of Panama (June 1940–October 1941, November 1949–May 1951, and Oct. 1–12, 1968) and three times deposed.

The younger brother of Harmodio Arias (Panamanian president, 1932–36), Arias was educated at the University of Chicago and Harvard Medical School (to become a surgeon) and was minister of agriculture and public works in the 1930s during the presidency of his brother. During his first term, he forced foreign businessmen to transfer their companies to Panamanian ownership and divested black West Indians in Panama of their citizenship. He sympathized with the Axis powers in World War II and opposed U.S. requests for defense installations. After the coup that deposed him (probably supported by the United States), he went into exile until 1945. During his dictatorial and corrupt second term, he replaced the constitution, dissolved the National Assembly and the Supreme Court, and was finally deposed by the police. Denied political rights from 1951 to 1960, Arias ran unsuccessfully for president in 1964, was elected in 1968, and was deposed by the military 11 days after taking office. He ran unsuccessfully for president in 1984.

Arias Dávila, Pedro, also called *PEDRARIAS DÁVILA* (b. 1440?, Segovia, Castile [Spain]—d. March 6, 1531, León, New Spain [now in Nicaragua]), Spanish soldier and colonial administrator who led the first Spanish expedition to found permanent colonies in the New World.

A soldier in his youth, Arias Dávila served with distinction in wars against the Moors in Granada in the 1490s and in North Africa in 1508–11. It is believed that he owed his appointment as captain general of the Spanish lands in the New World, which he received in 1513, to the bishop of Burgos. Arias Dávila sailed for the New World in 1514 with 19 ships and about 1,500 men.

Arias Dávila's accomplishments include establishing colonies in what are now Panama (1514) and Nicaragua (1522), serving as governor of Panama (1514–26) and Nicaragua (1527–31), and founding Panama City (1519). He also sent out expeditions of conquest, such as that led by Hernán Ponce and Bartolomé Hurtado to what are now Costa Rica and Nicaragua in 1516 and that led by Francisco Pizarro and Diego de Almagro, which conquered the Inca empire in what is now Peru in 1524. Arias Dávila, however, has been described both as being too old and as lacking the intellectual and moral capacity needed by a captain general. He seems to have deliberately promoted discord among the captains placed under his command, and he was held responsible for the trial and execution of the explorer Vasco Núñez de Balboa in 1519.

Arias de Saavedra, Hernando, byname *HERNANDARIAS* (b. 1561?, Asunción [now in Paraguay]—d. 1634, Santa Fe [now in Argentina]), Spanish-American explorer, soldier, and lieutenant governor (1591–93) and governor (1602–09, 1614–18) of the Spanish district of Río de la Plata in South America.

Hernandarias was known for his protection of the Indian population, for establishment of closer ties between the church and the civil authorities, and for encouraging the establishment of Jesuit and Franciscan missions. An efficient and incorruptible official, he inadvertently caused economic setbacks to the area by rigidly enforcing the laws against smuggling, an activity that had become virtually institutionalized under more lenient governors. Hernandarias founded the city of Corrientes (now in Argentina) and helped develop Buenos Aires, Santa Fe, and Asunción. During his second term as governor, the Río de la Plata was divided into two administrative units, one in Buenos Aires and another in Asunción, each with its own governor.

Arias Sánchez, Oscar (b. Sept. 13, 1941, Heredia, Costa Rica), politician and official, president of Costa Rica (1986–90), who was

awarded the Nobel Prize for Peace in 1987 for his Central American peace plan.

Born into one of the wealthiest coffee-growing families in Costa Rica, Arias Sánchez studied economics at the University of Costa Rica and earned a Ph.D. from the University of Essex in England. In the 1960s he began working for the moderate socialist National Liberation Party (Partido de Liberación Nacional; PLN), and in 1972 he was appointed minister of planning in the government of President José Figueres, a post he held until 1977. He was elected secretary-general of the PLN in 1979, and in 1986 he won the general election to become president of Costa Rica.

As president, Arias Sánchez took measures to cope with Costa Rica's heavy foreign indebtedness and other economic problems, but his main interest was in trying to restore peace and political stability to the strife-torn countries of Central America. While harshly critical of the Sandinista government in neighboring Nicaragua, he forbade that regime's guerrilla opponents (the "Contras") from operating militarily on Costa Rican soil. In February 1987 he proposed a regional peace plan for the Central American countries that would set a date for ceasefires between government and rebel forces, ensure amnesty for political prisoners, and schedule free and democratic elections in those countries. Arias and the leaders of Guatemala, El Salvador, Honduras, and Nicaragua signed this plan in August 1987. In October of that year Arias was awarded the Nobel Prize for Peace in recognition of his efforts to achieve the beginnings of peace in the region.

Aribau, Buenaventura Carles (b. Nov. 4, 1798, Barcelona, Spain—d. Sept. 17, 1862, Barcelona), economist and author whose poem *Oda a la patria* (1832; "Ode to the Fatherland") marked the renaissance of Catalan literature in the 19th century in Spain.

After working in Madrid at the banking establishment of Gaspar Remisa (1830–41), Aribau became the director of the treasury and financial secretary to the royal household. Animated by a deep patriotism, Aribau's work is marked by the early Romanticist concern with history. He was one of the editors of *El Europeo* and *El vapor*, two of the most important periodicals of the Romantic movement, the latter heavily reflecting the medievalist influence of the British novelist Sir Walter Scott. His *Oda a la patria*, upon which his fame rests, was a defense of regional feeling, written in the vernacular of Catalan, which attempted to unite contemporary intellectual trends with

Aribau, oil painting by J.E. Rull; in the Real Academia de Bellas Artes de San Jorge de Barcelona
Archivo Mas, Barcelona

native tradition. Aribau also edited, along with Manuel de Rivadeneyra, the first four volumes of the famous *Biblioteca de autores españoles* ("Library of Spanish Authors"), a monumental attempt to bring together all the important literature of Spain. (It filled 71 volumes upon completion in 1880.)

Ariböx (Mongol ruler): *see* Arigböge.

Arica, capital of Arica province, Tarapacá region, Chile. The city lies along the Pacific coast, at the foot of El Morro (a precipitous headland), and is fringed on its southern edge by sand dunes of the rainless Atacama Desert.

The harbour at Arica, Chile
Jacques Jangoux—Photo Researchers

Arica is situated near the Peruvian border and is the northernmost Chilean seaport. Founded as San Marcos de Arica in 1570 on the site of a pre-Columbian settlement, it belonged to Peru until 1879, when it was captured by the Chileans, who gained control of the locality under the Treaty of Ancón (1883). The question of Chile's legal possession was not finally resolved until 1929.

Until the mid-20th century, Arica served as a free port and handled considerable Bolivian transit trade. It is still a free port for Bolivia and a commercial centre for Peru and northern Chile, and various industries, chiefly fish meal processing and automobile assembly, have developed in the city. It is the terminus of an oil pipeline from Oruro, Bolivia. The irrigated Azapa and Río Lluta valleys yield farm produce for Arica and olives and citrus fruit for export. With its seaport, international airport, railways to Tacna, Peru, and La Paz, Bolivia, and its location on the Pan-American Highway, Arica is a transportation hub. It is also a beach resort for Bolivian society. Pop. (2002) 175,441.

aridisol, the dominant soil type of deserts and other relatively arid regions. First in abundance among the 10 orders of soil taxonomy, the aridisols cover about one-sixth of the total area of the world's soils. Supporting far less vegetation than the soils of humid regions, they have a low organic matter content. Winds play a major role in their development by blowing away fine particles, leaving a concentration of gravel or producing a desert pavement.

In areas where aridisols form, little water is available for leaching soluble salts or moving clay minerals. Most aridisols, at a certain depth, display a calcic horizon—a layer of calcium carbonate deposited by what little water manages to percolate downward from the surface. Although aridisols are unsuitable for cultivation in their natural state, they become highly productive when they are irrigated (as in the valleys of the western United States). Surface salinization can result, however, from excessive irrigation of aridisol soils that do not have adequate permeability.

Ariège, *département*, Midi-Pyrénées region, southern France, bordering Andorra and Spain. It embraces the widest and highest points of the Pyrenees, including many peaks over 9,000 feet (2,700 m) and passes above 6,000 feet, which remain snow-blocked for many months of the year. North of the core of the Pyrenees lie systems of parallel ridges and valleys. The outermost of these ridges, the

Montagne du Plantaurel, intersected by the Ariège River, drops steeply to the lowlands of Aquitaine. The outer limestone ranges have picturesque gorges, river tunnels, and caves. The town of Foix controls the Ariège gateway

into the mountains and the approach to the Col (pass) de Puymorens; this mountain pass has long provided an important road route into Spain. The lands of the ancient countship of Foix now form the nucleus of the *département*, which also includes parts of Languedoc and Gascony. Although it largely comprises the upper basin of the river Ariège, the *département* extends westward into that of the Salat headstream of the Garonne.

A pastoral economy prevails in the high mountains, and, as use of the summer pastures from the French side has decreased, more use has been made of them by Spanish shepherds. Corn (maize), haricot beans, potatoes, and deciduous fruits are cultivated in the lower valleys, and the mixed farming (wheat and corn) that is so typical of the lowlands of Aquitaine is practiced in the lower country in the north of the *département*. Although the mountains' pockets of high-grade iron ore have largely been depleted, lead and zinc deposits continue to be exploited. Gypsum and anhydrite mining are important at Tarascon, and talc at Luzenac. Hydroelectric power is an increasingly important economic factor, sup-

The Col (pass) de Puymorens, Ariège, France
Club Ins

porting aluminum refining at Sabart. A growing tourist industry has revived old spas such as Ax-les-Thermes. The limestone grottoes of Le Mas-d'Azil and Niaux are rich in Paleolithic archaeological remains.

Foix (the capital), Pamiers, and Saint-Girons head the *arrondissements*. Pamiers is the seat of the bishopric that is coextensive with the *département*. The court of appeal and the edu-

cational headquarters are outside the *département* at Toulouse. Area 1,888 square miles (4,890 square km). Pop. (2003 est.) 139,612.

Ariel, second nearest of the five major moons of Uranus. It was discovered in 1851 by the English astronomer William Lassell.

Ariel revolves around Uranus at a mean distance of 191,240 km (118,830 miles), taking 2.52 Earth days to complete one orbit. Its mean diameter is about 1,160 km (720 miles), and it is thought to consist of roughly equal parts water ice and rock, perhaps intermixed with a small amount of frozen methane.

Photographs taken by the Voyager 2 spacecraft in 1986 show that Ariel's surface is crisscrossed with scarps and long valleylike formations. Some of the latter are partially filled with materials that may have upwelled from the moon's interior in the past. In a few cases, ice appears to have spread from the valleys across broad plains, much like glacier flows on Earth. These features and the lack of large impact craters suggest that Ariel has the youngest surface of all of Uranus's major moons.

Ariel, the first international cooperative Earth satellite, launched April 26, 1962, as a joint project of agencies of the United States and the United Kingdom. Design, construction, telemetry, and launching of the 14.5-kilogram (32-lb) satellite was handled in the United States by the National Aeronautics and Space Administration. The United Kingdom was responsible for designing the equipment and the experiments to measure electron density and temperature and composition of positive ions, intensity of solar radiation in ultraviolet Lyman-alpha line, and cosmic rays.

Aries (Latin: "Ram"), in astronomy, zodiacal constellation lying between Pisces and Taurus, at about 3 hours right ascension (the coordinate on the celestial sphere analogous to longitude on the Earth) and 20° north declination (angular distance from the celestial equator).

Aries contains no very bright stars. The first point of Aries, or vernal equinox, is an intersection of the celestial equator with the apparent annual pathway of the Sun and the point in the sky from which celestial longitude and

right ascension are measured. It no longer lies in Aries but has been moved into Pisces by the precession of the equinoxes.

In astrology, Aries is the first sign of the zodiac, considered as governing the period *c.* March 21–*c.* April 19. Its representation as a ram is identified with the Egyptian god Amon and, in Greek mythology, with the ram with the golden fleece, on the back of which

Phrixus, the son of King Athamas, safely fled Thessaly to Colchis, where he sacrificed the

Aries, illumination from a Book of Hours, Italian, c. 1475; in the Pierpont Morgan Library, New York City (MS. G.14)

ram to Zeus, who placed it in the heavens as the constellation. The ram's golden fleece was recovered by Jason, leader of the Argonauts.

Arigböge, also spelled **ARIKBÖGE**, or **ARIBÖX** (d. 1266), brother of the great Mongol leader Kublai Khan and the Mongol chief most disposed toward Christianity.

As commander of the Mongol homeland when the great khan Mangu died in 1259, Arigböge had himself proclaimed the chief Mongol leader. Meanwhile, his elder brother, Kublai, returned from his campaigns in China and also assumed the title. A series of battles ensued, and Arigböge was finally defeated in 1264. Kublai held him prisoner until his death.

Arikara, American Plains Indian people of the Caddoan linguistic family who lived along the Missouri River between the Cheyenne River in South Dakota and Fort Berthold in North Dakota. The cultural roots of Caddoan-speaking peoples lay in the prehistoric mound-building societies of the lower Mississippi River valley. The Arikara were cultur-

"Bear's Belly—Arikara," photograph by Edward S. Curtis, 1908; from *The North American Indian*

Courtesy of the Edward E. Ayer Collection, The Newberry Library, Chicago

ally related to the Pawnee, from whom they broke away and moved gradually northward, becoming the northernmost Caddoan tribe.

The Arikara were expert in raising corn (maize), which they traded with other tribes for meat and robes. In addition, they raised beans, squash, tobacco, and sunflowers. The women did the farming; the men hunted deer, elk, and some buffalo. They lived in semipermanent villages of earth-covered lodges. Village activities were controlled by reference to a sacred bundle in the hands of a priest. This office and the posts of chiefs tended to be the hereditary prerogative of a few leading families. Lower posts were associated with organized military, dancing, and curing societies. The Arikara shared with other Plains tribes the practice of self-torture in tribal sun-dance ceremonies.

The Arikara became an obstacle to white trading parties moving up the Missouri River; a battle with traders in 1823 resulted in the first U.S. Army campaign against a Plains tribe. Although the Arikara had numbered between 3,000 and 4,000 near the end of the 1700s, wars and smallpox epidemics had severely reduced their numbers by the 19th century. In the 1860s they banded together with the Mandan and Hidatsa tribes at Fort Berthold, and a reservation was created for them there. By 1885 they had taken up farming on scattered family farmsteads. In the 1950s construction of Garrison Dam and the discovery of oil in the Williston Basin forced another removal to new homes.

aril, special covering of certain seeds that commonly develops from the seed stalk. It is often a bright-coloured fleshy envelope, as in such woody plants as the yews and nutmeg and in members of the arrowroot family, the genus *Oxalis*, and the castor bean. Animals are attracted to arils and eat the seeds, dispersing them in their wastes. In the castor bean, the aril is spongy and absorbs water during germination. The aril of nutmeg is the source of the spice known as mace.

Ariminum, Council of, also called **COUNCIL OF RIMINI** (AD 359), in early Christianity, one of the several 4th-century church councils concerned with Arianism; it was called by the pro-Arian Roman emperor Constantius II and held at Ariminum (modern Rimini, Italy).

It was attended by some 400 bishops of the Western Roman Empire, with the Eastern bishops simultaneously meeting at Seleucia (now Silifke, Turkey). The majority of bishops at Ariminum were orthodox and accepted the faith of Nicaea, but the Arian minority included skilled diplomats who successfully undid the orthodox decision of the majority when it reached the emperor. The orthodox bishops remaining at Ariminum were then forced to recant and subscribe to an Arian creed drawn up at Nice in Thracia. Pope Liberius soon repudiated this creed and declared the Council of Ariminum without authority.

Arinnitti, Hittite **WURUSEMU**, Hittite sun goddess, the principal deity and patron of the Hittite empire and monarchy. Her consort, the weather god Taru, was second to Arinnitti in importance, indicating that she probably originated in matriarchal times. Arinnitti's precursor seems to have been a mother-goddess of Anatolia, symbolic of earth and fertility. Arinnitti's attributes were righteous judgment, mercy, and royal authority. The powerful Hittite queen Puduhepa adopted Arinnitti as her protectress; the queen's seal showed her in the goddess' embrace.

Arinos River, Portuguese **RIO ARINOS**, river, west-central Brazil. It rises in the Araporé Mountains northeast of Diamantino and flows west for a short distance and then north-northwest across the Mato Grosso Plateau to its junction with the Juruena River, which is a major headstream of the Tapajós River.

Ariobarzanes (d. c. 360 bc), Persian satrap (provincial governor) of Phrygia after about 387. The son of a nobleman, he cultivated the friendship of Athens and Sparta and, about 366, led the unsuccessful revolt of the satraps of western Anatolia against the Persian king Artaxerxes II (reigned 404–359/358 bc).

Arion, semilegendary Greek poet and musician of Methymna in Lesbos. He is said to have invented the dithyramb (choral poem or chant performed at the festival of Dionysus); that is, he gave it literary form. His father's name, Cycleus, indicates the connection of the son with the cyclic or circular chorus of the dithyramb. None of his works survives, and only one story about his life is known.

After a successful performing tour of Sicily and Magna Graecia, Arion sailed for home. The sight of the treasure he carried roused the cupidity of the sailors, who resolved to kill him and seize his wealth. Arion, as a last favour, begged permission to sing a song. The sailors consented, and the poet, standing on the deck of the ship, sang a dirge accompanied by his lyre. He then threw himself overboard; but he was miraculously borne up in safety by a dolphin, which had been charmed by the music. Thus he proceeded to Corinth, arriving before the ship. There Arion's friend Periander, tyrant of Corinth, eventually learned the truth by a stratagem. Summoning the sailors, he demanded what had become of the poet. Upon affirming that he had remained behind, they were suddenly confronted by Arion himself. The sailors confessed and were punished, and Arion's lyre and the dolphin became the constellations Lyra and Delphinus.

Ariosto, Ludovico (b. Sept. 8, 1474, Reggio Emilia, duchy of Modena [Italy]—d. July 6, 1533, Ferrara), Italian poet remembered for his epic poem *Orlando furioso* (1516), which is generally regarded as the finest expression of the literary tendencies and spiritual attitudes of the Italian Renaissance.

Ariosto, woodcut after a drawing by Titian from the third edition of *Orlando furioso*, 1532

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd

Ariosto's father, Count Niccolò, was commander of the citadel at Reggio Emilia. When Ludovico was 10, the family moved to his father's native Ferrara, and the poet always considered himself a Ferrarese. He showed an inclination toward poetry from an early age, but his father intended him for a legal career, and so he studied law, unwillingly, at Ferrara from 1489 to 1494. Afterward he devoted himself to literary studies until 1499. Count Niccolò died in 1500, and Ludovico, as the eldest son, had to give up his dream of a peaceful life devoted to humanistic studies in order to provide for his four brothers and five sisters. In 1502 he became commander of the citadel of Canossa and in 1503 entered the service of Cardinal Ippolito d'Este, son of Duke Ercole I.

Ariosto's duties as a courtier were sharply at odds with his own simple tastes. He was expected to be in constant attendance on the cardinal and to accompany him on dangerous expeditions as well as travel on diplomatic missions. In 1509 he followed the cardinal in Ferrara's campaign against Venice. In 1512 he went to Rome with the cardinal's brother Alfonso, who had succeeded Ercole as duke in 1505 and had sided with France in the Holy League war in an attempt to placate Pope Julius II. In this they were totally unsuccessful and were forced to flee over the Apennines to avoid the pope's wrath. In the following year, after the election of Leo X, hoping to find a situation that would allow him more time to pursue his literary ambitions, Ariosto again went to the Roman court. But his journey was in vain, and he returned to Ferrara.

So far Ariosto had produced a number of Latin verses inspired by the Roman poets Tibullus and Horace. They do not compare in technical skill with those by Pietro Bembo, a contemporary poet and outstanding scholar, but they are much more genuine in feeling. Since about 1505, however, Ariosto had been working on *Orlando furioso*, and, indeed, he continued to revise and refine it for the rest of his life. The first edition was published in Venice in 1516. This version and the second (Ferrara, 1521) consisted of 40 cantos written in the metrical form of the ottava rima (an eight-line stanza, keeping to a tradition that had been followed since Giovanni Boccaccio in the 14th century through such 15th-century poets as Politian and Matteo Maria Boiardo). The second edition shows signs of Bembo's influence in matters of language and style that is still more evident in the third edition.

Orlando furioso is an original continuation of Boiardo's poem *Orlando innamorato*. Its hero is Orlando, whose name is the Italian form of Roland. *Orlando furioso* consists of a number of episodes derived from the epics, romances, and heroic poetry of the Middle Ages and Early Renaissance. The poem, however, achieves homogeneity by the author's skill and economy in handling the various episodes. Despite complete disregard of unity of action (which was to become compulsory in the second half of the century), it is possible to identify three principal nuclei around which the various stories are grouped: Orlando's unrequited love for Angelica, which makes him go mad (*furioso*); the war between Christians (led by Charlemagne) and Saracens (led by Agramante) near Paris; and the secondary love story of Ruggiero and Bradamante. The first is the most important, particularly in the first part of the poem; the second represents the epic background to the whole narrative; and the third is merely introduced as a literary courtesy, since the Este family was supposed to owe its origin to the union of the two lovers. The main unifying element, however, is the personality of Ariosto himself, who confers his own refined spirituality on all his characters. Sensual love is the prevailing sentiment, but it is tempered by the author's ironical attitude and artistic detachment. Upon its publication in 1516, *Orlando furioso* enjoyed immediate popularity throughout Europe, and it was to influence greatly the literature of the Renaissance.

In 1517 Cardinal Ippolito was created bishop of Buda. Ariosto refused to follow him to Hungary, however, and in the following year he entered the personal service of Duke Alfonso, the cardinal's brother. He was thus able to remain in Ferrara near his mistress, Alessandra Benucci, whom he had met in 1513. But, in 1522, financial necessity compelled him to accept the post of governor of the Garfagnana, a province in the wildest part of the Apennines. It was torn by rival political factions and overrun by brigands, but Ariosto showed great administrative ability in maintaining order there.

During this period, from 1517 to 1525, he composed his seven satires (titled *Satire*), modeled after the *Sermones* (satires) of Horace. The first (written in 1517 when he had refused to follow the cardinal to Buda) is a noble assertion of the dignity and independence of the writer; the second criticizes ecclesiastical corruption; the third moralizes on the need to refrain from ambition; the fourth deals with marriage; the fifth and sixth describe his personal feelings at being kept away from his family by his masters' selfishness; and the seventh (addressed to Pietro Bembo) points out the vices of humanists and reveals his sorrow at not having been allowed to complete his literary education in his youth.

Ariosto's five comedies, *Cassaria* (1508), *I suppositi* (1509), *Il negromante* (1520), *La lena* (1529), and *I studenti* (completed by his brother Gabriele and published posthumously as *La scolastica*), are based on the Latin classics but were inspired by contemporary life. Though minor works in themselves, they were among the first of those imitations of Latin comedy in the vernacular that would long characterize European comedy.

By 1525 Ariosto had managed to save enough money to return to Ferrara, where he bought a little house with a garden. Probably between 1528 and 1530 he married Alessandra Benucci (though secretly, so as not to forego certain ecclesiastical benefices to which he was entitled). He spent the last years of his life with his wife, cultivating his garden and revising the *Orlando furioso*. The third edition of his masterpiece (Ferrara, 1532) contained 46 cantos (a *giunta*, or appendix, known as the *Cinque canti*, or "Five Cantos," was published posthumously in 1545). This final version at last achieved perfection and was published a few months before Ariosto's death. (G.A.)

BIBLIOGRAPHY. Marinelli, *Ariosto and Boiardo: The Origins of Orlando furioso* (1987); Marianne Shapiro, *The Poetics of Ariosto* (1988); and Daniel Javitch, *Proclaiming a Classic: The Canonization of Orlando furioso* (1991).

Arisaema, genus of stemless, tuberous-rooted herbs, comprising about 190 species in the arum family (Araceae), native mostly to the Old World but including a few notable wildings of North America.

Of the hardy species often planted in the shady wild garden, two are especially familiar. The jack-in-the-pulpit, or Indian turnip (*A. triphyllum*), native to eastern North America, usually has two leaves, each about 25 cm (10 inches) long, three-parted, and on a leaf stalk up to 60 cm (24 inches) tall. The blossom consists of a greenish to purple tubelike spathe (the "pulpit"), 10 to 18 cm (4 to 7 inches) long, surrounding and covering with a drooping hood the green to purple rodlike spadix ("Jack"), which bears the small unisexual flowers. Varieties have colourful white to bronzy spathe markings and variant leaf shapes and sizes.

The green dragon, or dragonroot (*A. draconitium*), with leaves up to 25 cm in length on petioles up to 90 cm (35 inches) long, has an 8-centimetre-long greenish spathe, with an erect hood, surrounding a spadix that extends beyond the spathe by several times its length.

The rootstocks of both species are acrid, but those of *A. triphyllum* when cooked provided an Indian food. The red berries formed on the spadix are poisonous to humans but are eaten by many wild animals.

The curious cobra lily (*A. speciosum*), from Nepal and Sikkim state of India, has a slightly drooping spathe and a spadix decorated by a long threadlike extension. *A. fimbriatum*, from the Malay Peninsula, has a tasseled spadix.

'**Arish, Al-**, also spelled EL-ARISH, town and largest settlement of the Sinai Peninsula in the northeastern section, on the Mediterranean coast, the capital of Egypt's Shamāl Sinā' (Northern Sinai) *muḥāfaz̄ah* (governorate). It was under Israeli military administration from 1967 to 1979, when it returned to Egyptian rule. It is near the mouth of the Wadi al-'Arish, which is the longest seasonal watercourse of the Sinai.

Known as Rhinocorura (or Rhinocolura) to classical authors, the town is mentioned from at least the 2nd century BC. The Roman general Titus prepared his invasion of Judaea there (1st century AD). Later, Baldwin I, crusader king of Jerusalem, died there while returning from an Egyptian expedition (1118). It was prosperous as a Muslim trade centre in the European Middle Ages. Taken by Napoleon during his unsuccessful Palestine campaign (1799), Al-'Arish was the site of the signing of an abortive treaty providing for the French evacuation of Egypt.

In the early 20th century Al-'Arish and its environs were proposed as a site for Zionist colonization near, but not in, Palestine; the scheme was vetoed by Lord Cromer, British administrator of Egypt (1902). In 1906, when the administrative boundary between Egypt and Ottoman dominions proper was demarcated from the Mediterranean to the Gulf of Aqaba, Al-'Arish was placed definitively in Egypt. The town was formerly a station on the trans-Sinai railway, built by Britain in World War I; after 1967, however, Israel destroyed the line from Al-'Arish to the Suez Canal for security reasons.

The local economy is based on agriculture (date palms, castor beans), fishing, and quail trapping; there is a small castor-oil-producing plant. Commercial fishing in Lake al-Bardawil began in the late 1970s. Coal deposits just to the south of the town are used to fuel an electric-power plant that was started in the early 1980s. The governorate's offices are headquartered there, and the town has become a transfer point for materials passing between Egypt and Israel overland. Tourist facilities were opened in 1980 as well. Al-'Arish is linked by highway to the Suez Canal zone and Israel. It also has an airfield. Pop. (1986 prelim.) 67,638.

Arishima Takeo (b. March 4, 1878, Tokyo, Japan—d. June 9, 1923, Karuizawa), Japanese novelist known in his country as "the man of love" for his humanitarian idealism.

Arishima was the eldest son of a talented and aristocratic family; his younger brothers included the painter Arishima Ikuma and the novelist Satomi Ton. He went to the Peers School, where he was chosen as a companion to the crown prince. He went on to Sapporo Agricultural School (now Hokkaido University), which was noted in the late 19th century as a centre of modern thought. There he was awakened to the plight of the lower classes. Arishima had studied English from childhood, and, after graduating in 1896, he went to the United States, where he spent three years at Harvard University.

After returning to Japan, Arishima taught school in Sapporo and Kyōto; but in 1910 he joined his brothers and their friends Shiga Naoya and Mushanokōji Saneatsu in publishing the journal *Shirakaba* ("White Birch"), which was dedicated to disseminating the humanistic and benevolent ideals shared by the young men. Arishima seems to have struggled most deeply with the social contradictions inherent in his position as a wealthy aristocrat that conflicted with his ideal of universal love. His novel *Kain no matsuei* (1917; *Descendants of Cain*), dealing with the miserable condition of tenant farmers, attracted little attention,

but he soon received recognition with the novel *Aru oma* (1919; *A Certain Woman*, 1978). In 1922 he published *Sengen hitotsu* ("A Manifesto"), in which he expressed his despairing conviction that only the labouring classes could help themselves and that there was nothing he as a bourgeois ideologist could do for them. That year he distributed his land and farms in Hokkaido among the tenants; the following year he committed suicide with his mistress at a mountain retreat.

Aristaeus, Greek divinity whose worship was widespread but concerning whom myths are somewhat obscure. The name is derived from the Greek *aristos*, "best." According to the generally accepted account, Aristaeus, son of Apollo and the nymph Cyrene, was born in Libya but later went to Thebes, where he received instruction from the Muses in the arts of healing and prophecy and became the son-in-law of Cadmus and the father of Actaeon. After travelling extensively, Aristaeus reached Thrace, where he finally disappeared near Mt. Haemus.

Aristaeus was essentially a benevolent deity; he introduced the cultivation of bees and the vine and olive and was the protector of herdsmen and hunters. He was often identified with Zeus, Apollo, and Dionysus. He was represented as a young man dressed like a shepherd and sometimes carrying a sheep.

Ariṣṭanemi, also called NEMINĀTHA, 22nd of the 24 Tirthankaras, or saviours, of Jainism, a religion of India.

Though the last two saints (the 23rd and 24th) may be considered historical personages, the details of Ariṣṭanemi's life are obscured in legend. He is said to have lived 84,000 years before the coming of the next saint, Pārśvanātha; he is also said to have been a contemporary of the Hindu god Krishna, who was his cousin. On his marriage day, Ariṣṭanemi heard the cries of the animals that were to be slaughtered for the marriage feast and immediately renounced the world. The name Ariṣṭanemi is attributed to his mother's dream before he was born in which she saw a wheel of black jewels (Ariṣṭanemi, "the rim [*nemi*] of whose wheel is unhurt [*ariṣṭa*]"). In paintings he is always shown black in colour (in paintings of the Digambara sect, blue), and his symbol is the conch. He attained *mokṣa* (release from earthly existence) on the Girnār Hills in Kāthiāwār (western India), which has become a place of pilgrimage for the Jainas.

Aristarchus OF SAMOS (c. 310–230 BC), Greek astronomer, first to maintain that the Earth rotates and revolves around the Sun. On this ground, Cleanthes the Stoic declared that he ought to be indicted for impiety.

Aristarchus' advanced ideas on the movement of the Earth are known from Archimedes and Plutarch; his only extant work is a short treatise, "On the Sizes and Distances of the Sun and Moon." The values he obtained, by using geometry, are inaccurate, because of faulty observations.

Aristarchus found a more precise value for the length of the solar year. A lunar crater is named for him; a peak in its centre is the brightest formation on the Moon.

Aristarchus OF SAMOTHRACE (b. c. 217 BC—d. 145 BC, Cyprus), Greek critic and grammarian, noted for his contribution to Homeric studies.

Aristarchus in Alexandria, where he was a pupil of Aristophanes of Byzantium, and, c. 153 BC, became chief librarian there. Later he withdrew to Cyprus. He founded a school of philologists, called after him Aristarchians, which long flourished in Alexandria and afterward at Rome. Cicero and Horace regarded him as the supreme critic. His works fall

into three categories: (1) two editions of the text of Homer and editions of Hesiod, Pindar, Archilochus, Alcaeus, and Anacreon; (2) numerous commentaries on these poets and on Aeschylus, Sophocles, Aristophanes, and Herodotus; (3) critical brochures, especially on Homeric problems.

Aristeas, Letter of, pseudepigraphal work of pseudo-history produced in Alexandria, probably in the mid-2nd century BC, to promote the cause of Judaism. Though the size and prestige of the Jewish community had already secured for itself a definite place in Alexandrian society and serious anti-Semitism had not yet gained currency, the Jewish community was in conflict. While some Jews embraced Greek culture and philosophy, others refused any rapprochement with Hellenistic culture. The author's purpose was to present Judaism in a favourable light to pagans and make strict observance of religious laws attractive to Hellenistic Jews. The author assumed the name of a 2nd-century-BC writer and purported to give a contemporary account of the translation of the Hebrew Pentateuch, the first five books of the Bible, into Greek. He presented himself as a pagan admirer of Judaism who held a high position in the court of Ptolemy II Philadelphus (285–246 BC) in Alexandria. The writer used current Hellenistic literary conventions and the technical language of the Alexandrian court, but his Greek style and several historical inaccuracies indicate that he was a deliberate archaist. His concern for the welfare of Jewish slaves, his romantic picture of Palestinian Jewry, and his efforts to explain the theory behind Jewish dietary laws mark him as a Jew rather than a pagan.

Modern scholars call this work a "letter" because it was addressed by Aristeas to his brother Philocrates. The narrative draws upon a wide variety of sources: a report on Egyptian Jews from official archives, texts of Ptolemaic legal decrees, administrative memoranda preserved in royal files or in the Alexandria library, accounts of pilgrimages to Jerusalem, a treatise on the ideals of kingship, and an apology for Jewish law. The first writer to quote directly from the *Letter* was the Jewish historian Josephus (1st century AD). Several early Christians also used the book, ignoring its Jewish apologetic features.

Aristeides THE JUST: see Aristides.

Aristides (fl. 2nd century), Athenian philosopher, one of the earliest Christian Apologists, his *Apology for the Christian Faith* being one of the oldest extant Apologist documents. Known primarily through a reference by the 4th-century historian Eusebius of Caesarea, Aristides addressed his *Apology* either to the Roman emperor Hadrian (reigned 117–138) or to his successor Antoninus Pius (reigned 138–161). A primitive, general apology, Aristides' simple argument was the forerunner of the more personal and literary apologies in the late 2nd and early 3rd centuries, such as those produced by Athenagoras and Tertullian.

In the perspective of a pagan philosopher, Aristides' *Apology* begins with a discussion of the harmony in creation and, in the manner of the Stoic philosophers, establishes a correlation with the Divine Being responsible for the creation and preservation of the universe. Aristides reasons that such a Being would need to be eternal, perfect, immortal, all-knowing, the Father of mankind, and sufficient to himself. He then divides the pre-Christian human race into three categories according to their idea of deity and religious practices. In his judgment, all were inadequate: the barbarians, including the Babylonians (Chaldeans) and the Egyptians, with their cults of the elements of the universe and animals; the Greeks with their worship of anthropomorphic gods whose infamies made them anything but divine; and the Jewish monotheistic ideal, deserving re-

spect because of its faith in the Creator, genuine prophets, superior standards of morality, and social conscience, but excessive in devotion to angels and external ceremonies. Only the "new nation," as Aristides called the Christians, has a true idea of God, who creates all things through his Son and the Holy Spirit. Christian worship of God is manifested by a highly moral life based upon the commandments of Christ, to whom they look for the resurrection of the dead and life in the world to come. Profoundly impressed by the lofty mission of the new religion, Aristides stressed the charity of the Christian community and insisted that, although few in number, Christians were justifying the continued existence and salvation of the world by their intercession before God.

Long considered lost, Aristides' *Apology* was discovered in the late 19th century in fragmentary Armenian and Syriac versions. With the subsequent identification of a complete Greek version contained in the medieval Christian legend of Barlaam and Josaphat, the reconstruction of Aristides' original text finally was achieved. English translations were done by J.R. Harris (1893) and by D.M. Kay in *The Ante-Nicene Fathers* (1924).

Aristides QUINTILIANUS (fl. 2nd or 3rd century AD), Greek author of a treatise on music (*Peri musikês*), one of the principal sources of modern knowledge of ancient Greek music. The work deals with scales, metres, and the composition of melodies, as well as with the educational value of music and the relation of music, through mathematics, to phenomena in nature. It was regarded by Byzantine and Arab scholars as a basic work, and its importance is generally accepted by modern scholars. It was published in 1652, edited by Marcus Meibom; in 1882 in a critical edition by Albert Jahn; and in 1937, in German translation with commentary, by Rudolf Schäfke.

Aristides THE JUST, Aristides also spelled ARISTEIDES (fl. 5th century BC), Athenian statesman and general and founder of the Delian League, which developed into the Athenian Empire.

Little is known of Aristides' early life. He appears to have been prominent within the party that favoured resistance to Persia, but in 482 he was ostracized, probably because he opposed Themistocles' plan to use the silver from a new vein of the mines at Laurium to build a large fleet. Recalled in 480, Aristides distinguished himself in the decisive victory over the Persians near the island of Salamis (480) and commanded the Athenian army at the Battle of Plataea (479) when the Persians were driven from Greece.

The following year Aristides commanded the Athenian contingent of 30 ships in the fleet that the Spartan Pausanias led to free the Greek cities of Cyprus and capture Byzantium. Toward the end of the year the eastern Greek allies revolted from Spartan control and at Delos offered their allegiance, through Aristides, to Athens. The Delian League, based on Athenian naval power and the trust Aristides inspired, was his greatest achievement. Entrusted with the assessment of the members' contributions, Aristides carried out his task to general satisfaction, using as his basis the assessment imposed by the Persians on the Ionians in 493.

The military command of the league's forces passed to Cimon, and there is no reliable information about Aristides' later career or the date of his death. The view that Aristides was a democratic reformer is contradicted by the fact that his main associations were with Miltiades and Cimon, the enemies of the democratic leaders Xanthippus and Ephialtes.

Aristippus (b. c. 435 BC, Cyrene, Libya—d. 366, Athens), philosopher who was one of Socrates' disciples and the founder of the

Cyrenaic school of hedonism, the ethic of pleasure (*see* Cyrenaics). The first of Socrates' disciples to demand a salary for teaching philosophy, Aristippus believed that the good life rests upon the belief that among human values pleasure is the highest and pain the lowest (and one that should be avoided). He also warned his students to avoid inflicting as well as suffering pain. Like Socrates, Aristippus took great interest in practical ethics. While he believed that men should dedicate their lives to the pursuit and enjoyment of pleasure, he also believed that they should use good judgment and exercise self-control to temper powerful human desires. His motto was, "I possess, I am not possessed." None of his writings survives.

Aristo (philosopher): *see* Ariston of Chios.

Aristobulus I, also called JUDAS ARISTOBULUS (d. 103 BC), Hasmonean (Maccabean) Hellenized king of Judaea (104–103 BC).

The son of Hyrcanus I, he broke his late father's will and seized the throne from his mother and jailed or killed his brothers. According to the historian Josephus, Aristobulus conquered the Ituraeans of Lebanon and forcibly converted them to Judaism. He was the first of his house to adopt the title of king (*basileus*).

Aristobulus II (d. 49 BC), last of the Hasmonean (Maccabean) kings of Judaea.

On the death (67 BC) of his mother, Salome Alexandra, he succeeded to the throne, defeating his brother and rival, John Hyrcanus II (*q.v.*). When Hyrcanus sought help from the Nabataeans, the Romans under Pompey intervened and subjected Judaea to their rule (63 BC). After an unsuccessful attempt to regain power in 56, Aristobulus was sent to Rome as a prisoner and remained there until his death.

aristocracy, government by a relatively small privileged class or by a minority consisting of those felt to be best qualified to rule.

Politically, as conceived by Plato and Aristotle, aristocracy means the rule of the best few, the morally and intellectually superior, governing in the interest of the people. Such a form of government differs from the rule of one (monarchy or tyranny), of many (democracy), or of the selfish or militarily ambitious few (oligarchy or timocracy). Unfortunately, because "the best" is an evaluative and somewhat subjective notion, it is difficult objectively to distinguish aristocratic from oligarchic or timocratic governments. Because monarchy has its own aristocracy and because, in democracies, the people try to elect the best as their rulers, the aristocratic element is also present in these regimes. For these reasons aristocracy, in a more objective sense, means the upper layer of a stratified group. Thus, the upper ranks of the government form the political aristocracy of the state. The stratum of the highest dignitaries constitutes the aristocracy of the church. The richest captains of industry and finance constitute an aristocracy of wealth in an economic group.

The Brahman caste in the caste society of India, the Spartiates in Sparta, the eupatridae in Athens, the patricians or optimates in Rome, and the medieval nobility in Europe are examples of the social aristocracy or nobility in these groups and societies. Moreover, most such social aristocracies have been—both legally and factually—hereditary aristocracies (*i.e.*, those by reason of birth). Other aristocracies have been nonhereditary, recruited from different strata of the population, such as the upper stratum of the Roman Catholic Church, the ruling aristocracy of elective republics and monarchies, the leaders of scientific and artistic organizations, certain aristocracies of wealth, and even some emperors like the emperors of the Roman Empire, of whom about 43 percent were "upstarts."

The distinction between aristocracy of birth

and nonhereditary aristocracy is relative, however, because even in a caste society some lowborn persons climb into the higher castes and some of the highborn members slide down into the lower castes. On the other hand, even in open aristocracies there is always a tendency for the upper stratum to become a hereditary group filled mainly by the offspring of the aristocratic parents. In the United States, for example, among the living multimillionaires—the aristocracy of wealth—the percentage of those born of wealthy parents is notably higher than among the American multimillionaires of the middle of the 19th century.

Aristogiton: *see* Harmodius and Aristogiton.

Aristolochiales, the birthwort order of flowering plants, containing one family, Aristolochiaceae, which consists of 10 genera and about 600 species. *See* birthwort.

Aristomenes, traditional hero of an unsuccessful revolt against the Spartans by the Messenians, who had been enslaved by Sparta in the 8th century BC. Although Aristomenes is probably a historical figure, his career has been heavily overlaid with legend; the standard version makes him a leader of a rebellion about 650 BC—the so-called Second Messenian War. After several victories he was betrayed by King Aristocrates of Arcadia at the battle of "the Great Trench." For about 11 years he was besieged in Eira, Messenia. When the Spartans finally conquered that stronghold, Aristomenes escaped to live in exile on the island of Rhodes.

This tradition can probably be traced to the Greek historian Callisthenes of the 4th century BC. Rhianus, a Cretan poet of the 3rd century BC, wrote an epic in six books, placing Aristomenes in a revolt of 490 BC. In the 2nd century BC the historian Myron of Priene connected him with the original 8th-century Spartan conquest of Messenia. From these and other sources the Greek geographer Pausanias in the 2nd century AD compiled the longest surviving account, a story of the 7th-century rebellion with romantic embellishments drawn largely from Rhianus.

Ariston OF CHIOS, Ariston also spelled ARISTO (fl. mid-3rd century BC), Greek philosopher who studied under Zeno, the founder of the Stoic school of philosophy; he combined Stoic and Cynic ideas in shaping his own beliefs. Ariston believed that the only topic of genuine value in philosophy is the study of ethics and went even further in claiming that only general and theoretical issues are worth discussing in ethics and that there is only one true virtue in life—an intelligent, healthy state of mind.

Aristophanes (b. c. 450 BC—d. c. 388 BC), the greatest representative of ancient Greek comedy, and the one whose works have been preserved in the greatest quantity.

A brief treatment of Aristophanes follows. For full treatment, *see* MACROPAEDIA: Greek Dramatists, The Classical.

The little that is known of his life is derived mainly from Aristophanes' own words in the plays themselves. Aristophanes, son of Philippos, was an Athenian citizen belonging to the tribe named Pandionis. He began his career as a comic dramatist in 427 BC, and he is thought to have written about 40 plays in all.

Only 11 plays by him survive intact: *Acharnians*, *Knights*, *Clouds*, *Wasps*, *Peace*, *Birds*, *Lysistrata*, *Women at the Thesmophoria*, *Frogs*, *Women at the Ecclesia*, and *Wealth*. The early comedy *Babylonians* is extant only in fragments. Two posthumous comedies, *Aeolusicon* (probably a skit on Euripides' *Aeolus*) and *Kokalos* (also, presumably, a mythological burlesque), were produced in or about the year of his death by his son, Araros.

Aristophanes' dramatic activity covered the

end of the period of Old Comedy and the start of the so-called Middle Comedy; and though the line of demarcation between these two is shadowy, it is not unreasonable to say that the first 10 of Aristophanes' 11 surviving plays belong to the Old and the last to the Middle. Aristophanes' comedies are notable for their bold fantasy, merciless invective, outrageous satire, licentious humour, and marked freedom of political criticism. Among his special satirical targets were contemporary Athenian society, its fashionable philosophies and literature, and the aggressive foreign policy of Athens during the Peloponnesian War. His plays are still produced on the 20th-century stage in numerous translations that attempt to make the playwright's puns, witticisms, and topical allusions accessible to modern audiences.

Aristophanes OF BYZANTIUM (b. c. 257 BC—d. 180 BC, Alexandria), Greek literary critic and grammarian who, after early study under leading scholars in Alexandria, was chief librarian there c. 195 BC.

Aristophanes was the producer of a text of Homer and also edited Hesiod's *Theogony*, Alcaeus, Pindar, Euripides, Aristophanes, and perhaps Anacreon. Many of the *Arguments* prefixed in the manuscripts to Greek tragedies and comedies are ascribed to Aristophanes, and his study of Greek comedy led to separate works on Athenian courtesans and on character types. He revised and continued the *Pinakes* of Callimachus, a biographical history of Greek literature. As a lexicographer he compiled collections of archaic and unusual words, technical terms, and proverbs.

As a grammarian Aristophanes founded a school and wrote a treatise, *About Analogy*, which laid down rules for declension, etc. In editing the work of lyric and dramatic poets he introduced innovations in metrical analysis and textual criticism that were widely adopted by later scholars. Aristophanes also was responsible for arranging Plato's dialogues in trilogies, and he is generally credited with the foundation of the so-called Alexandrian Canon, a selection in each genre of literary work that contemporaries considered to be models of excellence.

Aristotelianism, the philosophy of Aristotle, and of those later philosophic movements based on his thought.

A brief treatment of Aristotelianism follows. For full treatment, *see* MACROPAEDIA: Aristotelianism, Aristotle and.

The range of Aristotle's thought was vast, covering logic, epistemology, metaphysics, ethics, physics, biology, zoology, psychology, literary theory, and politics. To Aristotle, logic was the basis for enunciating the conditions whereby thought can ascertain the causes of things. Aristotle was the first philosopher to have a clear understanding of some of the processes used in logic. He developed the system of syllogistic logic, whereby two valid propositions (the major and minor premises) give rise to a third and equally valid proposition (the conclusion). Aristotle also used inductive reasoning to try to establish the basic premises from which to make syllogistic deductions. He also mastered an extremely wide body of empirical data in the natural sciences, and much of his writing is descriptive in approach.

Aristotle created an extremely broad ontology, or theory of the nature and relations of being, in which individual substances interact in various ways to produce objects differing in such properties as substance, quantity, quality, time, position, and condition of action. The resulting framework enabled Aristotle to devise a philosophy of nature in which matter, or material constituents, undergo processes of dynamic and spontaneous change that are

in turn mediated by preexisting principles of form or structure. From this, Aristotle developed a hierarchy of existences that begin with the four primary bodies (earth, water, fire, and air), which make up more complex inorganic substances and then on to living organisms: plants possess the functions of growth, nutrition, and reproduction; animals possess in addition the functions of sensation, desire, and locomotion; and human beings in their turn possess the faculty of reason. With rational souls, humans can perform the highest activity, which is that of obtaining knowledge. Aristotle asserted that human goodness consists in the active exercise or use of the rational faculties.

Aristotle's philosophy was continued after his death by other members of his school such as Theophrastus and Eudemos of Rhodes. After the rediscovery and editing of Aristotle's works by Andronicus of Rhodes about 50 BC, Aristotelian thought was the subject of many expositions and commentaries in the Greco-Roman world. With the fall of the Roman Empire, most of Aristotle's works were lost in the West, though the logical works were known; others were preserved by Arabic, Syriac, and Jewish scholars and commentators, chief among whom were Avicenna and Averroës. Indeed, Islâmic philosophy between the 9th and 13th centuries was based on various interpretations of Aristotle's thought. Muslim scholars kept alive the Aristotelian heritage and passed it in the 12th and 13th centuries back to Europe, where Thomas Aquinas made Aristotelianism the philosophical basis for Christian theology (see Thomism). The authority of Aristotelianism declined with the rise of modern science, but it still subtly affects the orientation of Western modes of thought.

Aristotle, Greek ARISTOTELES (b. 384 BC, Stagira, Chalcidice, Greece—d. 322, Chalcis, Euboea), ancient Greek philosopher, scientist, and organizer of research, one of the two greatest intellectual figures produced by the Greeks (the other being Plato). He surveyed the whole field of human knowledge as it was known in the Mediterranean world in his day; and his writings long influenced Western and Muslim thought.

A brief treatment of Aristotle follows. For full treatment, see MACROPAEDIA: Aristotelianism, Aristotle and.

The son of the court physician to the king of Macedonia, Aristotle was probably introduced to Greek medicine and biology at an early age. Following the death of his father, he was sent to the Athenian Academy of Plato (367) and there engaged in dialogue for 20 years. On Plato's death in 348/347 he left Athens and traveled for 12 years, establishing new academies at Assus and at Mytilene. He lived at Pella, the capital of Macedonia, for about three years (beginning in 343/342), tutoring the future Alexander the Great, and retired to his paternal property at Stagira about 339. In 335 he returned to Athens and, at nearly the age of 50, opened the Lyceum, an institution to rival the Academy. For the next 12 years he organized it as a centre for speculation and research in every department of inquiry; the chief contributions of the Lyceum lay in biology and history. On the death of Alexander in 323, an anti-Macedonian agitation broke out in Athens, and Aristotle withdrew to Chalcis, north of Athens, where he died the following year.

Aristotle's extant works comprise mostly, it seems, notes used in giving Lyceum courses and are of a concentrated, academic nature. The form, titles, and order of the texts were given to them by Andronicus of Rhodes, the last head of the Lyceum, almost three centuries after the philosopher's death.

Aristoxenus (fl. late 4th century BC), Greek Peripatetic philosopher, the first authority for musical theory in the classical world.

Aristoxenus was born at Tarentum (now Taranto) in southern Italy and studied in Athens under Aristotle and Theophrastus. He was interested in ethics as well as in music and wrote much, but most of his work is lost. Apart from his musical treatises, fragments remain of his reconstruction of the old Pythagorean ethics as well as of his biographies of Pythagoras, Archytas, Socrates, and Plato. His theory that the soul is related to the body as harmony is to the parts of a musical instrument seems to follow early Pythagorean doctrine. In musical theory, Aristoxenus held that the notes of the scale should not be judged by mathematical ratio but by the ear. His remaining musical treatises include parts of his *Elements of Harmonics* (edited by P. Marquard, 1868, and by H. Macran, 1902) and of his *Elements of Rhythm* (edited by R. Westphal, 1861 and 1893) that are extant. The fragments of his other works were edited by F. Wehrli in *Aristoxenos, being part 2 of Wehrli's Die Schule des Aristoteles; Texte und Kommentar* (1945; "The School of Aristotle; Text and Commentary").

Arita ware: see Imari ware.

Aritan Stage, major division of Cretaceous rocks and time in Japan (the Cretaceous Period began about 144 million years ago and lasted until about 66.4 million years ago). Rocks of the Aritan Stage overlie those of the Kochian Stage and underlie those of the Lower Miyakoan Stage. The Aritan is correlated with the upper part of the Neocomian Stage, the lowermost standard worldwide division of the Cretaceous. The Aritan is characterized by distinctive ammonite cephalopods (mollusks).

arithmetic, branch of mathematics in which numbers, relations among numbers, and operations on numbers are studied and used to solve problems.

A brief treatment of arithmetic follows. For full treatment, see MACROPAEDIA: Arithmetic.

The numbers under consideration may be the natural numbers (1, 2, 3, . . .), the whole numbers or integers (. . . -3, -2, -1, 0, 1, 2, 3, . . .), the rational numbers (positive and negative fractional or decimal numbers, such as $\frac{1}{3}$, 0.68, $2\frac{2}{3}$, 3.7, $-\frac{7}{9}$, along with the integers), the real numbers (irrational numbers, such as $\sqrt{3}$, π , $\sin 32^\circ$, along with the rational numbers), or various more exotic number systems. The choice of number system depends on the physical situation that is to be dealt with by the arithmetic.

Virtually every known society has had some method of dealing with numbers. Very primitive systems may be as simple as having a name for "one" and a name for "more than one." A system of arithmetic developed among the Sumerians of Mesopotamia more than 5,000 years ago, and other societies in various parts of the world independently developed sophisticated systems of arithmetic.

The numeration system (or system for writing number symbols) widely used throughout the world today is a place-value system based on the number 10 and usually called the Arabic, or Hindu-Arabic, numeration system. In this system the position a symbol occupies helps determine the value of the symbol. For example, in 333, the 3 on the right means three, but the 3 in the middle means three tens and the 3 on the left means three hundreds. In modern Roman numerals (where I, V, X, L, C, D, and M are 1, 5, 10, 50, 100, 500, and 1,000, respectively), on the other hand, CCC means 300—each C stands for one hundred, and the relative position of the C's is of no importance. There are some rules regarding the order of symbols in the Roman numeral system, however (for example, IX means 9,

while XI means 11), though generally position is not as important as in place-value systems.

A place-value system, such as the Arabic numeral system, has clear advantages in economy of symbolism and in efficiency of computation. Only the 10 symbols 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9 and the decimal point are needed to write numbers of any size.

Arithmetic includes such esoteric subjects as the arithmetic of complex numbers and of quaternions, and number theory; but, for most practical purposes, the arithmetic of whole numbers and of rational numbers and the relation of these to the real world is sufficient.

arithmetic function, any mathematical function defined for integers, and dependent upon those properties of the integer itself as a number, in contrast to the algebraic functions or functions of analysis, which depend upon algebraic or limiting operations performed on numbers. Examples of arithmetic functions

n	$f(n)$
1	0
2	1
3	1
4	1
5	1
6	2
7	1
8	1
9	1
10	2
11	1
12	2

An arithmetic function; $f(n)$ equals the number of primes dividing n

include the following functions, which associate with each integer n one of the following numbers: (1) the number of divisors of n ; (2) the number of ways n can be represented as a sum or product of a specified number of integers; (3) the number of primes (integers not divisible by any number greater than one, except themselves) dividing n (including n itself). Arithmetic functions have applications in number theory, combinatorial analysis, counting, probability, and mathematical analysis, in which they arise as the coefficients of power series.

Arius (b. c. 250, Libya—d. 336, Constantinople [now Istanbul, Tur.]), Christian priest of Alexandria, Egypt, whose teachings gave rise to a theological doctrine known as Arianism (*q.v.*), which, in affirming the created, finite nature of Christ, was denounced by the early church as a major heresy.

An ascetical, moral leader of a Christian community in the area of Alexandria, Arius attracted a large following through a message integrating Neoplatonism, which accented the absolute oneness of the divinity as the highest perfection, with a literal, rationalist approach to the New Testament texts. This point of view was publicized about 323 through the poetic verse of his major work, *Thalia* ("Banquet"), and was widely spread by popular songs written for labourers and travelers.

The Council of Nicaea, in May 325, declared Arius a heretic after he refused to sign the formula of faith stating that Christ was of the

same divine nature as God. Influential support from colleagues in Asia Minor and from Constantia, the emperor Constantine I's daughter, succeeded in effecting Arius' return from exile and his readmission into the church after consenting to a compromise formula. Shortly before he was to be reconciled, however, Arius collapsed and died while walking through the streets of Constantinople.

Arius (river, Afghanistan): see Harīrūd.

ariya-puggala (Pāli: "noble person"), abbreviation ARIYA, Sanskrit ARYA-PUDGALA, in Theravāda Buddhism, a person who has attained one of the four levels of holiness. A first type of holy person, called a *sotāpanna-puggala* ("stream-winner"), is one who will attain Nirvana (the supreme goal of Buddhist thought and practice) after no more than seven rebirths. Another type of holy person is termed a *sakadāgamin* ("once-returner"), or one who is destined to be reborn in the human world only once more before reaching Nirvana. A third type of *ariya-puggala* is the *anāgamin* ("never-returner"), or one who will not be reborn in the human realm and will enter the realm of the gods at the time of death. The never-returner, however, is still not considered to have reached Nirvana.

The Theravāda Buddhist at the highest level of holiness is the arhat, one who has reached final and absolute emancipation from all rebirths in any human or superhuman realm. The arhat—a model person for Theravāda Buddhists—is to be distinguished from the personal ideal of the Mahāyāna Buddhist schools, the bodhisattva (*q.v.*, "buddha-to-be"). The latter is a holy person who has reached enlightenment but refuses to enter Nirvana, choosing rather to teach his insights until all creatures have similarly been liberated.

ʿarīyah (Arabic: "gratuitous loan"), in Islāmic law, the gratuitous loan of some object to another person for a specific period of time, upon which the lender recovers the object; *ʿarīyah* never involves the loan of money. The recipient is required under law to restore the object after use. Under an *ʿarīyah* contract, a Muslim may pay a debt by allowing his debtor to use, for example, his house or his land for a certain period of time while maintaining full ownership of the premises. *ʿArīyah* also enables an individual to lend possessions to another at a time when he would not be able to take care of them himself. The borrower is not, in principle, responsible for damage to the object arising from his authorized use of it, though the various schools of Islāmic law differ from each other in their doctrines on this point.

Ariyaramna (king of Persia): see Ariaramnes.

Arizona, constituent state of the United States of America, lying in the southwestern mountain region of the country.

A brief treatment of Arizona follows. For full treatment, see MACROPAEDIA: United States of America: *Arizona*.

Facing the Mexican state of Sonora to the south, Arizona is bounded by the U.S. states of New Mexico to the east, Colorado to the northeast, Utah to the north, and Nevada and California to the west. The capital is Phoenix. Roughly rectangular in shape, the state extends about 400 miles (650 km) from north to south and 340 miles (550 km) from east to west.

Human settlement in the area has spanned more than 25,000 years. The nomadic Apache and Navaho Indians arrived long after the collapse of the Anasazi and Hohokam civilizations and only a few centuries before the Spanish.

Spanish treasure seekers from Mexico, most notably Marcos de Niza and Francisco Coronado, made the initial European contact with the Indians of the region early in the 16th cen-

ture, thus establishing Mexico's claim to the area. In 1692 Father Eusebio Kino founded the first of many missions, and in 1776 the Mexican army built the first presidio, or fort, at Tucson. After the Mexican War, Arizona was ceded to the United States as part of New Mexico in 1848, and the Gadsden Purchase, an area south of the Gila River, was added in 1853. Arizona was organized as a territory in 1863 and became the 48th state in 1912.

Physiographically Arizona can be divided into three main regions: the Colorado Plateau of the north, containing large and often spectacular canyons, mesas, and remnants of volcanic mountains; the Basin and Range Province of the south, where isolated mountains rise from the desert plain; and the Transition Zone between them. Virtually all of Arizona's rivers are part of the Colorado River drainage system.

The climate of Arizona is mostly semiarid or arid. The southern Basin and Range Province has an average annual temperature of about 70° F (21° C), with annual rainfall in the west of about 3 inches (75 mm) increasing to 12 inches (300 mm) in the east. Year-round temperatures in the northern Colorado Plateau average 30 degrees cooler, with rainfall varying between 10 and 15 inches (250 and 380 mm). Summer thunderstorms, especially in July and August, are the main source of precipitation throughout most of the state.

Between 1970 and 1980 Arizona experienced a population increase of more than 50 percent, largely due to immigration there from other areas of the country that had a less benign climate or fewer economic opportunities. In spite of the tremendous growth, Arizona remains one of the least densely populated states. About one-sixth of the population is Spanish-speaking, most identifying themselves as Mexican. Another one-twentieth is Indian, thus constituting one of the largest Indian populations of any U.S. state. The largest Indian tribal groups are the Navajo, Hopi, Apache, Papago, and Pima.

Arizona's economy is well-diversified. Agriculture is based primarily on citrus fruits, cotton, and livestock. The main mining products are coal and copper ore. Arizona is the leading U.S. producer of copper ore. Lighter industries such as aerospace, electronics, and communications have developed rapidly and overtaken mining in importance. Large tourist expenditures in the state are a result of the warm winter climate and the scenery afforded by the natural landscape. About one-half of Arizona's land is owned by the federal government, including Grand Canyon and Petrified Forest national parks, seven national forests, and many national monuments, recreation areas, and historic sites. In addition to that role in Arizona's economy, the federal government also holds another one-quarter of Arizona's land in trust as Indian reservations and operates numerous military facilities.

Major universities in the state include the University of Arizona and Arizona State University. Art museums and symphony orchestras are located in both Tucson and Phoenix. The Arizona-Sonora Desert Museum near Tucson demonstrates the implications of human occupancy of the desert. Area 114,000 square miles (295,260 square km). Pop. (2000) 5,130,632.

Arjun (b. 1563, Goindwal, Punjab, India—d. May 30, 1606, Lahore, Punjab, Mughal Empire [now in Pakistan]), the Sikh religion's fifth Gurū and its first martyr.

Arjun compiled the *Adi Granth*, or *Granth Sāhib* ("Lord Book"), the sacred scripture of the Sikhs, a book revered almost as a god. One of the greatest of the Sikh Gurūs, he quickly completed the Harimandir, or the Golden Temple, at Amritsar, where all Sikhs could worship as they pleased. He expanded that great Sikh centre commercially and thus

was the first Gurū to serve as both temporal and spiritual head of the Sikhs. The social reform and missionary efforts by earlier Gurūs were extended under him.

Gurū Arjun prospered until the Mughal emperor Akbar died and his successor Jahāngir began to oppress the Sikhs. Rumours against the Gurū were spread by persons jealous of Arjun's popularity, and he was brought before Jahāngir, who fined him 200,000 rupees and ordered the elimination of all sections of the *Adi Granth* that gave offense to either Vedānta (Hinduism) or Islām. Gurū Arjun refused and was tortured to death. From that time on, the Sikhs, recognizing that they would be subject to further persecution by Mughal rulers, became more militaristic.

Arjuna, one of the five Pāṇḍava brothers, who are the heroes of the Indian epic the *Mahābhārata* ("Great Epic of the Bharata Dynasty"). Arjuna's hesitation before a battle became the occasion for his friend and charioteer, the god Krishna, to deliver a discourse on duty, or the right course of human action. These verses, which are in the form of a quasi-dialogue between Krishna and Arjuna, are collectively known as the *Bhagavadgītā*, which is the most celebrated religious text of India. See also Mahābhārata.

ark, also called ARK OF THE LAW, Hebrew ARON, or ARON HA-QODESH ("holy ark"), in Jewish synagogues, an ornate cabinet that enshrines the sacred Torah scrolls used for public worship. Because it symbolizes the Holy of Holies of the ancient Temple of Jerusalem, it is the holiest place in the synagogue and the focal point of prayer. The ark is reached by steps and is commonly placed so that the worshiper facing it also "faces Jerusalem." When the scrolls are removed for religious services, the congregation stands, and a solemn ceremony accompanies the opening and closing of the ark doors.

Ashkenazi (German-rite) Jews cover the doors of the ark with a richly embroidered cloth (parocheth), while Sephardic (Spanish-rite) Jews place the cloth inside. Before or near the cabinet hangs the eternal light (ner tamid), and generally an inscription of the Ten Commandments (often in abbreviated form) or some other relevant sacred text is placed above the doors.

Ark of the Covenant, Hebrew ARON HABERIT, in Judaism and Christianity, the ornate, gold-plated wooden chest that in biblical times housed the two tablets of the Law given to Moses by God. The Ark rested in the Holy of Holies inside the Tabernacle of the ancient Temple of Jerusalem and was seen only by the high priest of the Israelites on Yom Kippur, the Day of Atonement.

The Levites (priestly functionaries) carried the Ark with them during the Hebrews' wanderings in the wilderness. Following the conquest of Canaan, the Promised Land, the Ark resided at Shiloh, but from time to time it was carried into battle by the Israelites. Taken to Jerusalem by King David, it was eventually placed in the Temple by King Solomon. The final fate of the Ark is unknown.

ark shell, any of the species of predominantly marine bivalve mollusks of the family Arcidae. Such clams are characterized by boat-shaped shells with long, straight hinge lines bearing many small, interlocking teeth. The shells are usually coated with a thick, sometimes hairy periostracum (outer organic shell layer). Many of these clams have rows of simple eyes along the mantle margins. Most of the 200 or so known species are found in tropical seas, with relatively few occurring in temperate areas. Ark shells are slow-moving or sedentary. Many species, especially those

of the genera *Arca* and *Barbatta*, live attached by a byssus (a tuft of horny threads) in rock and coral crevices. Other species, particularly of the genus *Anadara*, live shallowly buried in sands and silts. Some species, such as the western African *Anadara senilis* and the Southeast Asian *Anadara granosa*, have provided a source of food for humans since prehistoric times.

Arkadelphia, city, seat (1842) of Clark county, south-central Arkansas, U.S. It lies along the Ouachita River south of that river's confluence with the Caddo River. The site was settled in about 1811 by John Hemphill, operator of nearby salt licks. It was known as Blakelytown until 1838, when the settlement adopted its present name, a combination of the name *Arkansas* and of *adelphia* (Greek: "brother-place"). Incorporated in 1857, it became a city of the second class in 1874 and of the first class in 1962. An agricultural and light-manufacturing economy prevails. Power is supplied by DeGray Dam on the Caddo. Arkadelphia is the home of Henderson State University (1890) and Ouachita Baptist University (1886). Pop. (2000) 10,912.

Arkadhía (Greece): see Arcadia.

Arkalyk, city and administrative centre of Turgay *oblast* (province), Kazakhstan. Settlement of the site began in 1956 in connection with the exploitation of the Turgay bauxite deposits, and it became a city in 1965. Arkalyk is linked to the Tselinograd-Tobol railway by a branch line from Yesil. In the late 20th century a major construction program was under way to provide the city with various urban amenities. Pop. (1999 est.) 45,700.

Arkān al-Islām: see Islām, Pillars of.

Arkansas (people): see Quapaw.

Arkansas, constituent state of the United States of America lying on the west bank of the Mississippi River, in the western south-central region of the country. The capital is Little Rock. Facing the states of Tennessee and Mississippi across the Mississippi River, Arkansas is also bounded by Missouri on the north, Oklahoma on the west, Texas on the southwest, and Louisiana on the south. The state is roughly square in shape and extends about 250 miles (400 km) in each direction.

A brief treatment of Arkansas follows. For full treatment, see *MACROPAEDIA*: United States of America: *Arkansas*.

The earliest inhabitants were Indian bluff dwellers along the banks of the Mississippi River whose farming and hunting culture flourished in about AD 500. Later mound-building cultures left sepulchral mounds and other remains along the Mississippi. At the time of initial European exploration the main Indian groups in the area were the Caddo, Osage, and Quapaw.

In the 16th and 17th centuries Spanish and French explorers traversed the region. The first permanent European settlement was founded at Arkansas Post in 1686 by the Frenchman Henri de Tonty. Arkansas was acquired by the United States as part of the Louisiana Purchase from France in 1803. Arkansas Territory was formed in 1819, and Arkansas entered the Union as the 25th state in 1836.

Arkansas seceded from the Union in 1861 and during the American Civil War was a member of the Confederate States of America. It was readmitted to the Union in 1868. Following Reconstruction a rigid policy of racial segregation evolved that ended in 1957 when federal troops entered Little Rock to maintain order after the state militia had been ordered to prevent the court-ordered desegregation of a public high school there.

Physiographically Arkansas can be divided

into two main regions roughly equal in size. A line drawn diagonally from the southwest corner to the northeast corner approximates the division between the forest-covered Ozark Plateau and Ouachita Mountains of the north and west and the fertile Gulf Coastal Plain and Mississippi River alluvial plain of the south and east. The state drains generally southeastward through the Arkansas and Mississippi rivers. Several large lakes have been created by damming streams in the Ozark and Ouachita mountains.

The Arkansas climate is temperate with mild winters and hot summers. Average temperatures at Little Rock, in the centre of the state at the border between the highlands and lowlands, are 42° F (6° C) in January and 82° F (28° C) in July. Annual precipitation of about 49 inches (1,250 mm) is distributed about equally during the year.

Settlement of the Mississippi River lowlands was primarily by slave-holding cotton planters from more easterly southern states. The state's black population in 1860 was about 110,000, or 25 percent of the total; by the late 20th century there were more than 387,000 blacks living in Arkansas, making up a decreasing percentage of the population. Statewide, barely more than half of the population lives in areas classified as urban. Little Rock, the largest city, is only a moderate-sized city. In recent years numerous "retirement villages" in the Ozarks have attracted many residents.

The Arkansas economy is no longer primarily agricultural, and cotton no longer dominates its agriculture. Rice, soybeans, corn (maize), and poultry are the major farm products. Reserves of bauxite (aluminum ore), obtained by strip-mining in the central region, represent most of the U.S. supply. The state's aluminum industries and most bauxite-mining operations, however, were suspended in the mid-1980s. Small quantities of bauxite were still mined for use in chemical-process industries. Nearly one-half of the state is covered by forests, notably extensive stands of pine and white oak. Hydroelectric power is produced at most dams, but steam-generated-power plants produce most of the state's energy. Two nuclear-power plants are in operation near Dardanelle. Manufacturing is chiefly of consumer goods, mostly food processing and the manufacture of wearing apparel, furniture, and electrical and nonelectrical machinery.

The entire lengths of the Arkansas and Mississippi rivers within Arkansas are navigable. Highways, railways, and airways crisscross the state.

Tourism is important to the economy; the most popular destinations are the mineral springs at Hot Springs National Park and the lakeside resorts in the Ozarks.

Eastern Arkansas is typically Southern in speech pattern and customs. Negro-spirituals and "soul music" flourished in Arkansas long before they became popular nationally. The rural areas of the Ozarks and Ouachitas have retained to the fullest degree their traditional folk arts and culture. The major higher-education institution is the University of Arkansas at Fayetteville. Area 53,187 square miles (137,754 square km). Pop. (2000) 2,673,400.

Arkansas City, city, Cowley county, southern Kansas, U.S. It lies near the confluence of the Arkansas and Walnut rivers. Founded in 1870, it was successively named Walnut City, Adelphi, and Creswell; the present name was adopted at the city's incorporation (1872). It was a starting place for the 1893 settlement of the Cherokee Strip in Indian Territory (now Oklahoma), and the Cherokee Strip Living Museum is 2 miles (3 km) south of the city. Oil was discovered nearby in 1914. Arkansas

City is a shipping centre and a railroad junction with repair shops. Oil refining, tile manufacturing, flour milling, meat-packing, and food processing are important industries. Cowley County Community College was founded there in 1922. Cowley State Fishing Lake is nearby. Pop. (2000) 11,963.

Arkansas Post, historic village, Arkansas county, southeastern Arkansas, U.S., on the Arkansas River. A fort, the first permanent white settlement in the lower Mississippi River valley, was built there in 1686 by Henri de Tonty, a lieutenant of René-Robert Cavalier, sieur de La Salle. It became the residence of the French and Spanish governors and was an important trading post. John Law's "Mississippi Bubble" (a development plan that ran afoul of speculative complications and political intrigue) attracted settlers to the area (1717), but most left after the speculative bubble "burst" in 1720. With the Louisiana Purchase, Arkansas Post served as the first capital of the Arkansas Territory (1819–21). During the American Civil War it fell to Federal troops and subsequently declined when bypassed by the railroads. Arkansas Post National Memorial (305 acres [123 hectares]) was created in 1960. White River National Wildlife Refuge is to the east.

Arkansas River, large tributary of the Mississippi River, rising in the Sawatch Range of the Rocky Mountains near Leadville in central Colorado, U.S., and flowing generally east-southeastward for 1,460 miles (2,350 km) through Kansas, Oklahoma, and Arkansas before entering the Mississippi 40 miles (64 km) northeast of Arkansas City, Ark. It has a total fall of 11,400 feet (3,475 m), and its drainage basin covers 161,000 square miles (417,000 square km).

From Leadville the Arkansas River flows southeast for about 100 miles (160 km) to Canon City, Colo., falling 6,750 feet (2,060 m). It leaves the mountains near Canon City

Arkansas River near Leadville, Colo.

S. Vovnick—Shostal

through the Royal Gorge, a narrow canyon cut into solid granite with vertical walls more than 1,000 feet (300 m) high. The Purgatoire River enters the Arkansas just above the John Martin Reservoir (1948), near Las Animas, Colo. Between Canon City and Great Bend, Kan., the Arkansas River's channel is wide and shallow and meanders through a dry area that is extensively irrigated. Heavy rainfalls upstream will occasionally cause floods. Southeastward from Great Bend the river flows through a more humid area and is frequently more than 0.5 mile (0.8 km) wide with a deep channel. The river receives its main tributaries in the Oklahoma portion: the Salt Fork, Cimarron, Verdigris, Grand, and Canadian rivers. The Arkansas River Navigation System enters the river 5 miles (8 km) northeast of Muskogee, Okla., at the mouth of the Verdigris River, and continues through Arkansas to the Mississippi. Many water-control projects have been established in the Arkansas River basin, including a multiple-purpose reservoir at Eufaula on the Canadian River near McAlester, Okla. Princi-

pal riparian cities are Pueblo, Colo.; Wichita, Kan.; Tulsa, Okla.; and Fort Smith and Little Rock, Ark.

The Arkansas is believed to have been crossed by the Spanish explorer Francisco Vázquez de Coronado in 1541 near the site of Dodge City, Kan., and in 1806 the American explorer Zebulon Pike travelled through the upper reaches.

Arkansas River Navigation System, official name McCLELLAN-KERR ARKANSAS RIVER NAVIGATION SYSTEMS, improved portion of the Verdigris and Arkansas rivers, extending southeastward for 439 mi (767 km) from Catoosa (near Tulsa) in northeastern Oklahoma, U.S., through Arkansas to the Mississippi River 25 mi north of Arkansas City, Ark. Approved by the U.S. Congress in 1946 and completed in January 1971, the project controls the Arkansas River's regular flooding and provides a navigable waterway for year-round shipment of the river basin's resources—agricultural products, lumber, petroleum, and coal. Seventeen dams and locks along the waterway, which is 250 ft (75 m) wide and 9 ft deep, create a large supply of hydroelectric power.

Arkatag, also spelled ARKHA TAGH, also called PRZHEVALSKY RANGE, one of the complex mountain chains that form the Kunlun Mountains in western China. The Arkatag is the highest range of the Kunluns with the peaks of Ulugh Muz Tagh at its western end and Shapka Monomakha (also known as Chong Karlik Tagh) at the eastern end, both more than 25,300 ft (7,700 m).

Arkell, Anthony John (b. July 29, 1898, Hinxhill, Kent, Eng.—d. Feb. 26, 1980, Chelmsford, Essex), historian and Egyptologist, an outstanding colonial administrator who combined a passion for the past with a humanitarian concern for the peoples of modern Africa.

After serving with the Royal Flying Corps and the Royal Air Force, Arkell joined the Sudan Political Service in 1920 and set about abolishing the slave trade between the Sudan and Ethiopia, establishing villages for the freed slaves, who called themselves "the Sons of Arkell." He was appointed commissioner for archaeology and anthropology in 1938 and undertook several digs that opened up the previously unknown field of Sudanese prehistory. He returned to England in 1948 and was appointed curator of the Flinders Petrie Collection of Egyptian Antiquities at University College, University of London; he reorganized and cataloged this collection while writing his authoritative *History of the Sudan* (1955). He was professor of Egyptology at University College until his retirement in 1963, when he was ordained.

Arkell, William Joscelyn (b. June 9, 1904, Highworth, Wiltshire, Eng.—d. April 18, 1958, Cambridge, Cambridgeshire), paleontologist, an authority on Jurassic fossils (those dating from 208 to 144 million years ago). Arkell taught at Trinity College, Cambridge University. His work includes the classification of Jurassic ammonites and an interpretation of the environments of that period. He wrote *Jurassic Geology of the World* (1956), which stimulated further development of a stratigraphical classification applicable to all geological systems and periods.

Arkhangelsk, *oblast* (province), Russia, along the northern coast of European Russia, from the Gulf of Onega to the Yugorsky Peninsula. Centred in Arkhangelsk city, it encompasses the Nenets autonomous *okrug* (district) in the east and a number of islands, including the Solovets, Novaya Zemlya, and Franz Josef Land archipelagoes. The low morainic hills and broad valleys are covered by tundra

in the north and dense taiga (swampy forests) of spruce, pine, and birch in the south. Timber working dominates the economy. There is some fishing on the coasts and rivers and reindeer herding among the Nenets people. Area 226,800 square miles (587,400 square km). Pop. (1991 est.) 1,577,200.

Arkhangelsk, English ARCHANGEL, city and administrative centre of Arkhangelsk *oblast* (province), Russia, on the Northern Dvina River, 30 miles (50 km) from the White Sea. With its suburbs, Solombala and Ekonomiya, the city extends for 10 miles along the river. Founded in 1584 as the fortified monastery of the archangel Michael, it was the first port of the Russian Empire to conduct trade with England and later with other countries. The

Docks at Arkhangelsk, Russia
Novosti Press Agency

port reached the height of its prosperity in the 17th century but subsequently declined with the founding of St. Petersburg (1703) and the exorbitant customs dues introduced by Peter I the Great to divert trade to his new town. Arkhangelsk later revived with the building of a railway from Moscow in 1898. It is now the largest timber-exporting port of Russia. It has large-scale timber-processing industries, including sawmilling and pulp making and papermaking. Shipbuilding and repair are important. Arkhangelsk is the base for a fishing fleet and the western terminus of the Northern Sea Route. There are institutes of epidemiology and of forestry and a teachers college. Pop. (1991 est.) 428,200.

Arklow, Irish AN TINBHEAR MÓR, port, seaside resort and urban district on the Irish Sea coast, in County Wicklow, southeast Ireland. In 431 St. Palladius, the Christian missionary, landed at the present site of Arklow. The Vikings had a settlement there, and the town was granted by John of England in 1189 to Theobald Fitz-Walter, Lord Butler of Ireland. It was an English stronghold during the late medieval period, and there are remains of a 13th-century Dominican friary and fragments of the Butler castle. Small boats, pottery, and fertilizers are manufactured there. Pop. (1986) 8,388.

Arkona, West Slavic citadel-temple of the god Svantovit, dating from the 9th–10th century AD and destroyed in 1168/69 by Christian Danes when they stormed the island of Rügen in the southwestern Baltic. Saxo Grammaticus, the 12th-century Danish historian, wrote that the Arkona was a wooden structure of consummate workmanship; around the temple extended a yard, and around this was a wooden fence, splendidly carved and bearing various painted symbols. The temple itself was log-built and was topped by a red roof; the inner chamber had partitions of heavy tapestry. In this inner sanctum loomed the statue of

Svantovit, larger than life size, awe-inspiring with its four heads and throats joined together facing in opposite directions. Saxo mentions that not only the whole land of Wends but also Scandinavian neighbours paid tribute to Svantovit. When the statue was cut and removed, the Danes carried away seven boxes of treasures (gifts to the god). C. Schuchhardt's excavation in 1921 proved the actual existence of the temple. Repeated excavations in 1969–70 revealed an earlier layer of the sanctuary dated to the 10th and possibly 9th century AD.

arkose, coarse sandstone (sedimentary rock composed of cemented grains 0.06–2 millimetres [0.0024–0.08 inch] in diameter) presumed to have formed by the disintegration of a granite without appreciable decomposition. Arkose thus consists primarily of quartz and feldspar grains together with small amounts of mica, all moderately well sorted, slightly worn, and loosely cemented with calcite or, less commonly, iron oxides or silica. Arkoses are distinguished from the normal quartzose sandstones (orthoquartzites) by their high feldspar content (more than 25 percent of the sand grains) and from the graywackes by their lighter colour. The feldspar content of subarkoses is 5–25 percent of the sand grains; it is diminished by more extensive weathering or by dilution from nonigneous source rocks. In the absence of stratification, arkose may bear superficial resemblance to granite, and it aptly has been described as reconstituted granite, or granite wash. Like the granites from which they were formed, arkoses are pink or gray.

The geological significance of arkose has been much debated. Under normal conditions most of the feldspar decomposes and is converted to clay minerals during weathering of the source rocks, whereas under conditions of extreme dryness or low temperatures, decomposition of the feldspar is inhibited or greatly retarded. Arkoses were, therefore, presumed to be derived from the erosion of a granitic terrane characterized by an arid or glacial climate. Now, however, it is known that the feldspar may escape destruction and thus be transported and deposited with quartz sands if rates of uplift, erosion, and deposition are great enough. Under such conditions, irrespective of the climate, weathering processes are incomplete and the sands derived from such terrane are high in feldspar content. Arkoses, therefore, may be said to indicate either a climatic extreme or high relief. Most ancient arkose deposits seem to be the product of high relief.

Arkwright, Sir Richard (b. Dec. 23, 1732, Preston, Lancashire, Eng.—d. Aug. 3, 1792, Cromford, Derbyshire), textile industrialist and inventor whose use of power-driven machinery and employment of a factory system

Arkwright, detail of an engraving by J. Jenkins after a portrait by Joseph Wright

By courtesy of the Science Museum, London

of production were perhaps more important than his inventions.

In his early career as a wig-maker, Arkwright traveled widely in Great Britain and began his lifelong practice of self-education. He became interested in spinning machinery at least by 1764, when he began construction of his first machine (patented in 1769). Arkwright's water frame (so-called because it operated by waterpower) produced a cotton yarn suitable for warp. The thread made on James Hargreaves' spinning jenny (invented about 1767) lacked the strength of Arkwright's cotton yarn and was suitable only for weft. With several partners, Arkwright opened factories at Nottingham and Cromford. Within a few years he was operating a number of factories equipped with machinery for carrying out all phases of textile manufacturing from carding to spinning.

He maintained a dominant position in the textile industry despite the rescinding of his comprehensive patent of 1775. He may have borrowed the ideas of others for his machines, but he was able to build the machines and to make them work successfully. By 1782 Arkwright had a capital of £200,000 and employed 5,000 workers. In 1786 he was knighted.

Arlberg, mountain pass and tunnel, at the northern end of the Rhaetian Alps, in western Austria. The pass (at 5,882 feet [1,793 m]) forms a divide between the Danube and Rhine river systems. The region is a noted winter sports area, and the Arlberg technique in skiing was perfected there by Hannes Schneider, who was born at Stuben am Arlberg. A rail tunnel 6.3 miles (10.2 km) long, built in 1880–84, carries an electrified railroad between Langen (Vorarlberg) and Sankt Anton (Tirol); the two towns were connected by a road tunnel 8.7 miles (14 km) in length that opened in 1979.

Arllecchino: see Harlequin.

Arlen, Harold, original name HYMAN ARLUCK (b. Feb. 15, 1905, Buffalo, N.Y., U.S.—d. April 23, 1986, New York, N.Y.), American composer, arranger, pianist, and vocalist who contributed such popular songs as "Over the Rainbow," "Blues in the Night," "Come Rain or Come Shine," "I Love a Parade," and "Stormy Weather" to Hollywood movies and Broadway musicals. Arlen was most prolific from 1929 through the 1950s.

The son of a Jewish cantor and a pianist, Arlen showed exceptional musical talent in childhood. He left school as a teenager to form a band, and, until he was 24, he made a living chiefly as a performer and arranger. Thereafter he concentrated on composition, beginning a successful collaboration with the lyricist Ted Koehler in 1929 with the song "Get Happy." From the late 1920s until the mid-1930s Arlen and Koehler wrote a number of songs, including "Between the Devil and the Deep Blue Sea" and "I've Got the World on a String," that were featured in shows at Harlem's Cotton Club. Arlen's work for the Broadway stage included scores for the musicals *You Said It* (1931); *Life Begins at 8:40* (1934); *Hooray for What?* (1937); *Bloomer Girl* (1944); *St. Louis Woman* (1946) and *Saratoga* (1959), both with lyrics by Johnny Mercer; and *House of Flowers* (1954), with lyrics by Truman Capote.

For Hollywood films, Arlen wrote, among other songs, "It's Only a Paper Moon," "Let's Fall in Love," Groucho Marx's theme song "Lydia the Tatoo'd Lady," and "That Old Black Magic." "Over the Rainbow" (lyrics by E.Y. Harburg), introduced by Judy Garland in *The Wizard of Oz* (1939) and used thereafter as her theme, won him a 1939 Academy Award. Arlen also worked with Ira Gershwin on music for the film *The Country Girl* (1954),

starring Bing Crosby, and he recorded as a vocalist with Leo Reisman and Cole Porter. He was widely honoured for his life achievements by both film and theatre societies.

Arlen, Michael, original name DIKRAN KOUYOUMDJIAN (b. Nov. 16, 1895, Ruschuk, Bulg.—d. June 23, 1956, New York, N.Y., U.S.), British author whose novels and short stories epitomized the brittle gaiety and underlying cynicism and disillusionment of fashionable post-World War I London society.

The son of an Armenian merchant, Arlen was brought up in England, to which his father had escaped to avoid Turkish persecution. By 1916 he was living in London, enjoying the company of such writers as D.H. Lawrence and George Moore and writing articles for periodicals and journals. He took the name Michael Arlen in 1922, when he became a British subject, and wrote two books of short stories before his first novel, "*Piracy*" (1922), was published. His best-known work was published two years later; the phenomenal popular success of *The Green Hat* (1924)—a witty, sophisticated, but fundamentally sentimental novel about the "bright young things" of Mayfair, London's most fashionable romantic district of the period—made him famous almost overnight in Great Britain and the United States.

After 1928, when he married the Countess Atalanta Mercati, Arlen lived mainly in the south of France. Though he was for a time much celebrated, Arlen never repeated the popular success of *The Green Hat*, which had been adapted for both stage (starring Tallulah Bankhead) and screen (as *A Woman of Affairs*, starring Greta Garbo). He wrote a screenplay, *The Heavenly Body* (1944), and a number of books, including *Man's Mortality* (1933) and the thriller *The Flying Dutchman* (1939), before retiring to New York City in 1945.

Arles, ancient (Latin) ARELATE, city, Bouches-du-Rhône *département*, Provence-Alpes-Côte-d'Azur *région*, southeastern France, on the Camargue plain where the Rhône River divides to form its delta, northwest of Marseille. Already important in the days of the Ligurian tribes, Arles became a leading city of the Western Roman Empire. St. Trophime in the 1st century AD founded the bishopric, which endured until 1790.

The city fell to the Visigoths in the 6th century and then to Muslim invaders in 730. In the 10th century it became the capital of the kingdom of Burgundy, known later as the kingdom of Arles, and in the 12th century emerged as an independent entity—much like the Italian republics—preeminent

in commerce and navigation. In 1239 it was absorbed into Provence. Portions of the wall around the old town are Roman, and a Roman arena dating to the 1st century BC that seated more than 20,000 spectators is still used for bullfights and plays. Excavations at a Roman theatre have retrieved many art objects, including the "Vénus d'Arles" now in the Louvre. The Church of Saint-Trophime was founded in the 7th century and was rebuilt several times. The city of Arles was also home to the painter Vincent van Gogh during one of his most productive periods.

A naval base under the Romans, Arles is still a river port, mainly for oil tankers. Industries include chemical, metal, and paper manufacture, but the economy is largely based on tourism and agriculture. Pop. (1990) 52,058.

Arles, Council of (AD 314), the first representative meeting of Christian bishops in the Western Roman Empire. It was convened at Arles in southern Gaul in August 314 by Emperor Constantine I, primarily to deal with the problem of the Donatists, a schismatic Christian group in North Africa. Attended by representatives of 43 bishops, this synod was held because the Donatists had denied the representative character of two earlier synods, at Rome and in Africa, at which they had been condemned. At Arles the Donatists were again condemned, but they rejected the decisions reached by the council and again appealed to Constantine to review their case.

Arletty, pseudonym of ARLETTE-LÉONIE BATHIAT (b. May 15, 1898, Courbevoie, near Paris, Fr.—d. July 24, 1992, Paris), French actress with a distinguished international reputation for her film characterizations.

Arletty worked for a time in a factory and as a secretary before becoming an artist's model and chorus girl. In 1920 she joined the Théâtre des Capucines and appeared there in innumerable revues as well as at other Parisian theatres in operettas (such as *Oui*, 1928) and comedies (such as *Fric Frac*, 1936; "Burglary").

Arletty made her film debut in *Un Chien qui rapporte* (1930; "A Dog That Fetches") and played minor film roles for many years. Finally, when Marcel Carné cast her as the prostitute who longed for a better life, in *Hôtel du Nord* (1938), she achieved star status. Similar roles in Carné's *Le Jour se lève* (1939; *Daybreak*) and *Les Visiteurs du soir* (1942; *The Devil's Envoys*) established her worldwide reputation as the interpreter of the quintessential sophisticated Parisian woman. Arletty's most famous motion-picture role, however, was as the courtesan Garance in *Les Enfants du Paradis* (1945; *Children of Paradise*), again directed by Carné.

At the end of World War II Arletty was briefly jailed for collaboration (she had refused work with German filmmakers but had taken a German lover). She did not complete another film until 1949 (*Portrait d'un assassin*), the same year she also created the role of Blanche in the first French stage production of Tennessee Williams' *A Streetcar Named Desire*. The following year saw another stage success as the lead in *Revue de l'empire*. During the next 12 years Arletty continued to appear in plays and to make films, most notably playing Inez in the screen version of Jean-Paul Sartre's *No Exit* (*Huits-clos*, 1954) and a cameo role in one of the few films she made for a non-French company, *The Longest Day* (1962). Although by 1963 she had become almost blind, she eventually returned to the stage, notably in the leading role in Jean Cocteau's *Les Monstres sacrés* (1966; "The Holy Monsters"), and to films as a madam in Jean-Claude Brialy's *Les Volets fermés* (1972; "The Closed Shutters"). An autobiography, *La Défense*, was published in 1971.

Arlington, urban town ("township"), Middlesex county, eastern Massachusetts, U.S., im-

mediately northwest of Boston. Settled in 1635 as part of Cambridge, it was known as Menotomy (from an Algonquian word meaning "swift waters") until separately incorporated as West Cambridge in 1807. It was renamed for George Washington Parke Custis's Virginia estate in 1867, when it was also reincorporated. Its early economy depended on market gardening, the shipping of ice (cut from the town's Spy Pond), and the manufacture of textile cards. The town developed as a residential suburb with the arrival of the railway from Boston in 1846. The local economy is dominated by services and wholesale and retail trade, and there also is some light manufacturing. Arlington's Jason Russell House (1680) was the scene of a fierce skirmish with the British in which 12 minutemen were killed on April 19, 1775. Their graves are marked in the old cemetery of the town's Unitarian Church. Pop. (2000) 42,389.

Arlington, city, Tarrant county, northern Texas, U.S., between Fort Worth (west) and Grand Prairie and Dallas (east). The first settlement (1843), on an Indian council site, was called Bird's Fort and then Johnson's Station. In 1876 Arlington was laid out by railroad men and named for Gen. Robert E. Lee's home in Virginia. Primarily an industrial and commercial centre, it has automotive and aerospace industries that developed after 1950, with an accompanying rapid increase in population. It is the seat of the University of Texas at Arlington (1895) and the Arlington Baptist College (1939). Six Flags Over Texas, a large amusement park, and Arlington Stadium, home of the Texas Rangers baseball team, are located there. Inc. 1920. Pop. (2000) city, 332,969; Fort Worth-Arlington PMSA, 1,702,625.

Arlington, urban county in northern Virginia, U.S., across the Potomac River (southwest) from Washington, D.C., with which it is connected by five bridges (Francis Scott Key, Arlington Memorial, George Mason, Theodore Roosevelt, and Rochambeau Memorial), and adjoining the city of Alexandria (south).

Established as Bellehaven (later Alexandria) county, it was ceded to the federal government in 1789 and became part of the District of Columbia; the county was returned to Virginia in 1846 and was renamed Arlington in 1920 for the former estate of the Custis-Lee families. Arlington has developed from a number of small villages (including Arlington, the county seat) into an integral part of metropolitan Washington. Governed as a unit, it has no incorporated places.

One of the smallest counties in the nation, Arlington covers 24 square miles (62 square km) of which about 20 percent is federal property occupied by Arlington National Cemetery, Ronald Reagan Washington National Airport, Fort Myer, and the Pentagon (Department of Defense) and other government offices. The county has become a residential and bustling business community with clusters of high-rise buildings and some light manufactures (electric components, scientific instruments, machinery). Housing developments include Ballston, Buckingham, Cherrydale, Clarendon, Columbia Pike, East Falls, Fairlington, Rosslyn, and Westover. Marymount University (Roman Catholic) was founded (1950) in Arlington. Pop. (2000) 189,453.

Arlington, Henry Bennet, 1st earl of, also called (1663-72) **BARON ARLINGTON** (b. 1618, Little Saxham, Suffolk, Eng.—d. July 28, 1685, Euston, Suffolk), secretary of state under King Charles II of England from 1662 to 1674 and a leading member of Charles's "Cabal" ministry. Besides directing foreign policy for 12 years, Arlington, by creating the nucleus of a "court party" (the future Tories) in the House of Commons, helped to develop the party system in England.

Bennet served as Charles's agent in Madrid

Arlington, detail of an oil painting from the studio of Sir Peter Lely, 1665; in the collection of the Marquess of Bath

while both were in exile after the English Civil War. As secretary of state, Bennet (created Baron Arlington in 1663 and given an earldom in 1672) survived parliamentary censure for the conduct and result of the second Anglo-Dutch War (1665-67). With the fall of the 1st Earl of Clarendon, the lord chancellor, in 1667, Arlington became in effect the chief minister of state.

A skeptic in religion (although on his deathbed he professed himself a Roman Catholic), he used the fear of popery to rouse popular feeling against France. In 1668, with Sir William Temple (one of the outstanding men whom Arlington brought into the King's service) as intermediary, he negotiated the Protestant Triple Alliance of England, the Dutch Republic, and Sweden. Because he was in the King's confidence, however, Arlington was ambiguously involved in Charles's pro-French and pro-Catholic policies that were embodied in the secret Anglo-French Treaty of Dover (1670), in which Charles agreed, among other things, to support Louis XIV of France in war against the Dutch Republic. Although Arlington supported measures intended to effectuate the Dover treaties (a second treaty having been signed openly later in 1670), he was thought to have taken bribes from the Dutch, with whom England concluded peace in 1673.

In 1674 Arlington, denounced by the 2nd Duke of Buckingham, was impeached for embezzlement, "betrayal of trust," and promoting Roman Catholicism. The charges failed, but Arlington resigned the secretaryship of state (Sept. 11, 1674) for the safer but lucrative position of lord chamberlain. He held that office until his death early in the reign of James II, whose exclusion from the succession to the throne Arlington may have proposed. See V. Barbour, *Henry Bennet, Earl of Arlington* (1914).

Arlington Heights, village, Cook county, northeastern Illinois, U.S., about 25 miles (40 km) northwest of Chicago. Settled in 1836, it was known as Dunton for William Dunton, the original settler, until the present name was adopted in 1874. The village developed as a residential suburb and has some light industry, including telecommunications research. Arlington Park, a horse racing track, is just west. The city is the site of a local historical museum. Inc. 1887. Pop. (2000) 76,031.

Arlington National Cemetery, American national burial ground in Arlington County, Virginia, U.S., on the Potomac River directly opposite Washington, D.C. It occupies a tract of more than 500 ac (200 ha) and is generally semicircular in shape; its central feature is the mansion built in 1802 on the estate of George Washington Parke Custis, adopted son of George Washington. The mansion is said to have been modelled after the Theseum in

Athens. The portico, with its eight white columns, is a landmark visible from across the river. The mansion, now called Arlington House, serves as the Robert E. Lee Memorial.

When Lee, who had married Mary Anne Randolph Custis in the mansion in 1831, left Arlington (April 22, 1861) to command the Confederate troops in the Civil War, federal soldiers occupied the estate, converting the mansion into a headquarters and the grounds into a camp. Arlington became a military cemetery in 1864 by order of the secretary of war. After years of litigation George Washington Custis Lee, the residuary legatee, succeeded through the U.S. Supreme Court in declaring the government a trespasser. He sold the title to the U.S. for \$150,000 in 1883.

The first soldier buried there (May 13, 1864) was a Confederate prisoner who died in a local hospital. Some of the dead from every war in which the U.S. has participated, including a few officers of the American Revolution, have since been buried there. Many of the nation's military leaders and other outstanding individuals, including Gen. John J. Pershing, Adm. Richard E. Byrd, William Howard Taft, Robert E. Peary, Gen. Jonathan Wainwright, Gen. George C. Marshall, Robert Todd Lincoln, Maj. Pierre-Charles L'Enfant, William Jennings Bryan, John F. Kennedy, and Robert F. Kennedy, also are buried there.

The Tomb of the Unknown Soldier, first a memorial to the dead of World War I but now also considered a memorial to the dead of other wars, is located there. Nearby is the Memorial Amphitheatre, erected through the efforts of the Grand Army of the Republic as a place of assembly for Memorial Day services and dedicated May 15, 1920. The roofless, white marble structure, enclosing a natural amphitheatre, is copied after both the Theatre of Dionysus at Athens and the Roman theatre at Orange, Fr.

Arlington remains an active military cemetery, with an average of 7,000 funerals each year. By 2000 there were more than 260,000 people buried on the grounds. Based on its burial rate, the cemetery was expected to reach capacity by 2020, after which time it will operate as a national shrine.

Arliss, George, original name **AUGUSTUS GEORGE ANDREWS** (b. April 10, 1868, London—d. Feb. 5, 1946, London), actor noted for his portrayal of historic personages in many motion pictures.

Arliss, 1938

By courtesy of the National Film Archive, London

Arliss began his acting career in 1887 but did not have his first substantial success until he appeared with Mrs. Patrick Campbell in London during the 1900-01 season. In 1902 he played in *The Second Mrs. Tanqueray* in New York City and in 1911 played the title role in *Disraeli*.

Arliss was already established as a leading actor when he turned to films in 1920. His pictures included *The Green Goddess* (1930), *Old English* (1930), *Alexander Hamilton* (1931),

The House of Rothschild (1934), and *Cardinal Richelieu* (1935). He won an Oscar for best actor of 1929–30 for his role in the film version of *Disraeli*. Arliss wrote several plays and two autobiographical works: *Up the Years from Bloomsbury* (1927) and *My Ten Years in the Studios* (1940).

Arlon (French). Flemish AARLEN, capital of Luxembourg province, southeastern Belgium. It lies at the foot of the southern end of the Ardennes Plateau near the source of the Semois River and the border of Luxembourg. It originated as the Roman Orolaunum and is the oldest known settlement in Belgium. It lies on the road from Trier to Reims and was fortified in the 4th century. It became the seat of a countship in the 10th century. From its castle Richard I the Lion-Heart, who was also Marquis d'Arlon, set out for the Third Crusade (1190). With Belgian independence, Arlon became the provisional capital of Luxembourg province (1830, confirmed 1839).

Arlon has become an important livestock and agricultural market and a frontier station on the international Brussels–Namur–Luxembourg railway. There is some manufacturing, and part of its population is employed in steel plants across the borders in Luxembourg and in France.

Warfare during the 16th, 17th, and 18th centuries destroyed most of the relics of Arlon's past. Chief among the remains are the Roman Tower (from the 4th-century fortifications dismantled by the French in 1670) and the 17th-century Church of St. Donatus. Arlon's archaeological museum contains valuable Roman tomb reliefs. Pop. (1983 est.) mun., 22,201.

Arlt, Roberto (b. April 2, 1900, Buenos Aires, Arg.—d. July 26, 1942, Buenos Aires), novelist, short-story writer, dramatist, and journalist who pioneered the novel of the absurd in Argentinian literature.

A first-generation descendant of German immigrants, Arlt felt alienated from Argentine society. The world of his novels *El juguete rabioso* (1926; "The Rabid Toy"), *Los siete locos* (1929; "The Seven Madmen"), *Los lanzallamas* (1931; "The Flame Throwers"), and *El amor brujo* (1932; "False Love") is grotesque and nightmarish and is filled with anguished, half-insane characters who are in revolt against society. His *Aguafuertes porteñas* (1950; "Etchings from the Port") and *Nuevas aguafuertes porteñas* (1960), originally published as articles in *El Mundo*, are picaresque sketches of the people of Buenos Aires that show great psychological perception and intense irony. Among Arlt's plays, *Trescientos millones* (1932; "Three Hundred Million") and *Saverio el cruel* (1936; "Saverio the Cruel," not staged until 1956) stand out. *Trescientos millones* is rich in its use of experimental techniques, and *Saverio* is notable for its treatment of reality along Pirandellian lines. Arlt's complete fictional works were published in 1963.

arm, in zoology, either of the forelimbs or upper limbs of ordinarily bipedal vertebrates, particularly humans and other primates. The term is sometimes restricted to the proximal part, from shoulder to elbow (the distal part is then called the forearm). In brachiating (tree-swinging) primates the arm is unusually long.

The bones of the human arm, like those of other primates, consist of one long bone, the humerus, in the arm proper; two thinner bones, the radius and ulna, in the forearm; and sets of carpal and metacarpal bones in the hand and digits in the fingers. The muscle that extends, or straightens, the arm is the triceps, which arises on the humerus and attaches to the ulna at the elbow; the brachialis

and biceps muscles act to bend the arm at the elbow. A number of smaller muscles cover the radius and ulna and act to move the hand and fingers in various ways. The pectoralis muscle, anchored in the chest, is important in the downward motion of the entire arm and in quadrupeds pulls the limb backward in locomotion.

The term arm may also denote the limb or the locomotive or prehensile organ of an invertebrate, such as the ray of a starfish, tentacle of an octopus, or brachium of a brachiopod.

Armada, also called SPANISH ARMADA, or INVINCIBLE ARMADA, Spanish ARMADA ESPAÑOLA, OF ARMADA INVENCIBLE, the great fleet sent by King Philip II of Spain in 1588 to invade England in conjunction with a Spanish army from Flanders (now in Belgium). England's attempts to repel this fleet involved the first naval battles to be fought entirely

and clear the Strait of Dover for Parma's army to cross from Flanders over to southeastern England.

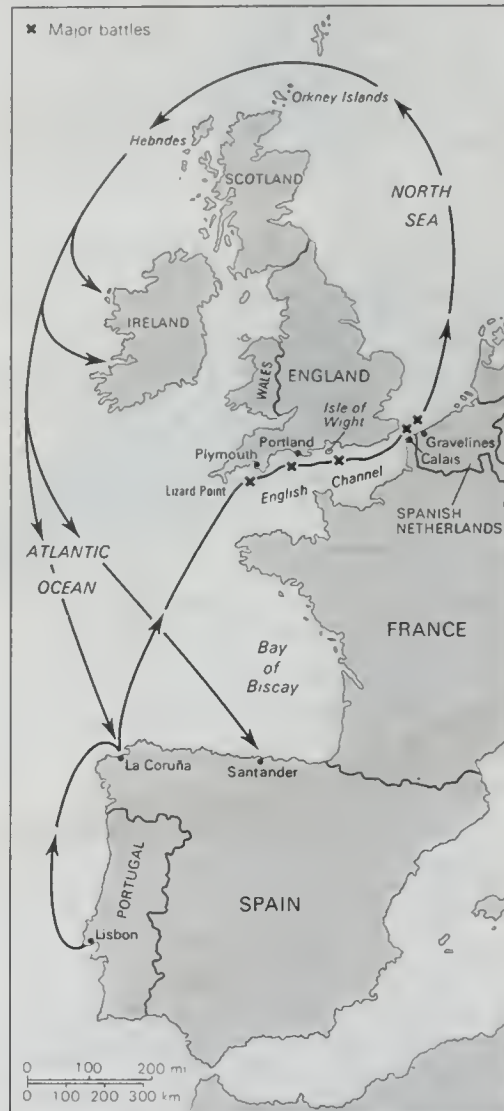

After nearly two years' preparation and prolonged delays, the Armada sailed from Lisbon in May 1588 under the command of the Duke of Medina-Sidonia, a replacement for Spain's most distinguished admiral, the Marquess de Santa Cruz, who had died in February. Medina-Sidonia was an experienced administrator who proved to be resolute and capable in action, but he had relatively little sea experience. The Spanish fleet consisted of about 130 ships with about 8,000 seamen and possibly as many as 19,000 soldiers. About 40 of these ships were line-of-battle ships, the rest being mostly transports and light craft. The Spaniards were conscious that even their best ships were slower than those of the English and less well armed with heavy guns, but they counted on being able to force boarding actions if the English offered battle, after which the superiority of the Spanish infantry would prove decisive.

The English fleet was under the command of Charles Howard, 2nd Baron Howard of Effingham; he was no more experienced an admiral than Medina-Sidonia but was a more effective leader. His second in command was Sir Francis Drake. The English fleet at one time or another included nearly 200 ships; but, during most of the subsequent fighting in the English Channel, it numbered less than 100 ships, and at its largest it was about the same size as the Spanish fleet. No more than 40 or so were warships of the first rank; but the English ships were unencumbered by transports, and even their smallest vessels were fast and well armed for their size. The English placed great reliance on artillery; their ships carried few soldiers but had many more and heavier guns than the Spanish ships. With these guns, mounted in faster and handier ships, they planned to stand off and bombard the Spanish ships at long range.

Gales forced the Armada back to the port of La Coruña (in northern Spain) for refitting, and it finally got under way again in July. The Armada was first sighted by the English off Lizard Point, in Cornwall, on July 29 (July 19, Old Style). The larger part of the English fleet was then at Plymouth, dead to leeward, but by a neat maneuver was able to get to the windward, or upwind, side of the enemy (i.e., west of the Armada, given the prevailing west winds) and hence gain the tactical initiative. In three encounters (off Plymouth, July 31 [July 21]; off Portland Bill, August 2 [July 23]; and off the Isle of Wight, August 4 [July 25]), the English harassed the Spanish fleet at long range and easily avoided all attempts to bring them to close action but were unable to inflict serious damage on the Spanish formation.

The Armada reached the Strait of Dover on August 6 (July 27) and anchored in an exposed position off Calais, Fr. The English also anchored, still to windward (west of the Armada), and were reinforced by a squadron that had been guarding the narrow seas. The first certain news of the Armada's advance reached Parma in Flanders the same day, and he at once began embarking his troops in their invasion craft; but the process required six days, and the Armada had no safe port in which to wait for him, nor any means of escorting his small craft across the coastal shallows where Dutch and English warships cruised to intercept them. This defect in Spanish strategy was to prove disastrous.

At midnight on August 7–8 (July 28–29), the English launched eight fire ships before the wind and tide into the Spanish fleet, forcing the Spanish ships to cut or slip their cables (thus losing their anchors) and stand out to sea to avoid catching fire. The Spanish ships' formation was thus completely broken. At dawn on the 8th the English attacked the disorganized Spanish ships off Gravelines, and a decisive

Route of the Armada, 1588

with heavy guns, and the failure of Spain's enterprise saved England and the Netherlands from possible absorption into the Spanish empire.

Philip had long been contemplating an attempt to restore the Roman Catholic faith in England, and English piracies against Spanish trade and possessions offered him further provocation. The Treaty of Nonsuch (1585) by which England undertook to support the Dutch rebels against Spanish rule, along with damaging raids by Sir Francis Drake against Spanish commerce in the Caribbean in 1585–86, finally convinced Philip that a direct invasion of England was necessary. He decided to use 30,000 troops belonging to the veteran army of the Spanish regent of the Netherlands, the Duke de Parma, as the main invasion force, and to send from Spain sufficient naval strength to defeat or deter the English fleet

battle ensued. The English ships now closed to effective range and were answered largely with small arms. The Spanish ships' heavy guns were not mounted, nor were Spanish gunners trained to reload in action. They sustained serious damage and casualties without being able to reply effectively. Three Spanish ships were sunk or driven ashore, and others were badly battered. At the same time the English were obliged by shortage of ammunition to break off the action and follow at a distance. By the morning of August 9 (July 30), the prevailing westerly winds were driving the Spaniards toward the shoals of the Zeeland banks. At the last minute, however, the wind shifted and allowed them to shape a safe course to the northward. Both the west wind and the English fleet now prevented the Armada from rejoining Parma, and it was forced to make the passage back to Spain around the northern tip of Scotland. The English fleet turned back in search of supplies when the Armada passed the Firth of Forth and there was no further fighting, but the long voyage home through the autumn gales of the North Atlantic proved fatal to many of the Spanish ships. Whether through battle damage, bad weather, shortage of food and water, or navigational error, some ships foundered in the open sea, while others were driven onto the west coast of Ireland and wrecked. Only 60 ships are known to have reached Spain, many of them too badly damaged to be repaired, and perhaps 15,000 men perished. The English lost several hundred, perhaps several thousand, men to disease but sustained negligible damage and casualties in action.

The defeat of the Armada saved England from invasion and the Dutch Republic from extinction, while dealing a heavy blow to the prestige of the greatest European power of the age. Tactically the Armada action has enduring historical significance as the first major naval gun battle under sail and as the moment from which, for over two and a half centuries, the gun-armed sailing warship dominated the seas.

armadillo, any of numerous mammals of the family Dasypodidae, order Edentata, related to sloths and anteaters. Armadillos are found in tropical and subtropical regions, primarily in South America; most species inhabit open areas, but some live in forests.

There are 9 genera and 20 species of armadillos. The three-, six-, and nine-banded armadillos (*Tolypeutes*, *Euphractus*, and *Dasypus*, respectively) are named for the number of

Nine-banded armadillo (*Dasypus novemcinctus*)

Appel Color Photography

movable bands in their armour. One species of nine-banded armadillo (*D. novemcinctus*) is the only armadillo to range into the United States, where it reaches as far as northern Texas. The pichi (*Zaedyus pichi*) is a common small resident of Argentinian Patagonia.

Armadillos are stout, short-legged animals with strong, curved claws and protective coverings of pinkish to brown armour. The armour is composed of solid, bucklerlike plates separated by movable transverse bands. It covers most of the body, including the head

and usually the tail. The coat ranges from a scattering of hairs in such forms as the nine-banded armadillos (*Dasypus*) to a comparatively dense coat of soft, white hair on the underparts and sides in the pink fairy armadillo, or lesser pichiciago (*Chlamyphorus truncatus*). The size of armadillos varies considerably, from an overall length of about 16 cm (6.5 inches) in the pink fairy armadillo to about 1.5 m (5 feet) in the giant armadillo (*Priodontes giganteus*).

Armadillos live alone, in pairs, or in small groups. They are primarily nocturnal and live in burrows, coming out to feed on termites and other insects, vegetation, small animals, and some carrion. They are strong diggers and are also good swimmers, swallowing air to make themselves buoyant in water. Armadillos are timid animals. When threatened, they retreat to their burrows or, if caught in the open, draw in their feet so their armour touches the ground. They may also run away, burrow, or claw at the attacker. The three-banded armadillos (*Tolypeutes*) are able to roll up into a ball as a means to protect their vulnerable underparts. The pink fairy armadillo and Burmeister's armadillo (*Burmeisteria retusa*) have vertical armour plates on their hindquarters. The pink fairy armadillo uses this plate to plug the entrance to its burrow, and Burmeister's armadillo probably does the same.

Some species of female armadillos bear one to 12 identical young, all of which develop from a single fertilized egg. The gestation period, which is not known for all armadillos, is about 65 days in one species of peludo, or hairy armadillo (*Chaetophractus villosus*). It is four months in one of the nine-banded armadillos (*D. novemcinctus*), not including a delay of several months between fertilization of the egg and its implantation in the wall of the uterus.

armadillo lizard (species *Cordylus cataphractus*), a southern African member of the family Cordylidae, known for its defensive body posture. This lizard is about 25 cm (10 inches) long. When danger threatens, it forms a ball by rolling on its back and taking its tail in its mouth. Protected by hard, bony scales and spines on the head and tail, the armadillo lizard remains in this position until the danger disappears.

Armageddon (probably Hebrew: "Hill of Megiddo"), in the New Testament, place where the kings of the Earth under demonic leadership will wage war on the forces of God at the end of world history. Armageddon is mentioned in the Bible only once, in Revelations, or The Revelation to John (16:16). The Palestinian city of Megiddo was probably used as a symbol for such a battle because of its strategic importance in Palestinian history. Because it controlled a pass that cut through the Mount Carmel ridge from the coastal Plain of Sharon into Esdraelon, Megiddo commanded the road leading from Egypt and the coastal plain of Palestine into Galilee, Syria, and Mesopotamia. Megiddo was the scene of many battles, and Revelations seems to imply that the "hill" on which the city fortress stood, or the "mountain" heights behind it, had become a symbol of the final battlefield where God's heavenly armies will defeat the demon-led forces of evil. Other biblical references suggest Jerusalem as the site of this battle.

Armagh, former (until 1973) county, Northern Ireland. It was bounded by Lake Neagh (north), former County Tyrone (northwest), former County Down (east), and by the Republic of Ireland (south and west).

In late prehistoric times and at the dawn of history, Armagh was an important populated area in Ulster. At the beginning of the Christian era, the fortress of Emain Mhacha, at the site known as Navan Fort, served as the cen-

tre of a kingdom of Ulster extending to the Rivers Shannon and Boyne in the west and south. Also associated with that period is an ancient frontier earthwork, Black Pig's Dyke. Following the decline of Ulster in the 4th century, Emain Mhacha lost its importance; and Ard Mhacha (now Armagh, the county town) became the political centre. It gained added importance after St. Patrick made it his metropolitan see in the 5th century. The area was later ravaged by Anglo-Norman and also Danish (841) invaders, but they made no permanent settlements.

Not until the 17th century did English influence become important in the county. Made shire ground in 1586 and included in the scheme for the Plantation of Ulster of the early 17th century, Armagh was colonized mainly by Protestant landowners from England. Armagh's prosperity in the 18th century is attested to by many monuments and buildings. In the 1973 administrative reorganization of Northern Ireland, the county was divided into the district of Armagh and portions of Craigavon and Newry and Mourne districts.

Armagh, Irish ARD MHACHA, city, seat, and district (established 1973), formerly in County Armagh, Northern Ireland. The hill fort of Ard Mhacha, around which modern Armagh city developed, became important in the 4th century. In the 5th century St. Patrick established his principal church in Ireland on the hill-fort site, which later became a medieval ecclesiastical capital. Armagh's capture by English (Protestant) forces in the 16th century was followed by the opening of a number of educational institutions, including a Royal school (1627), a library, and an observatory (1765). The prosperity of the Protestant clergy and gentry in the 18th century is reflected in the city's many Georgian monuments and buildings. Contemporary Armagh is the seat of both Church of Ireland (Anglican) and Roman Catholic archbishoprics, and the city is the market centre for the district and manufactures textiles, chemicals, optical items, and processed foods.

Armagh district covers an area of 261 square miles (676 square km) located south of Lake Neagh and is bordered by the districts of Dunganon to the northwest, Craigavon to the northeast, Banbridge to the east, Newry and Mourne to the southeast, and the Republic of Ireland to the southwest. Southern Armagh district is rugged terrain that slopes gradually down to more fertile lowlands in the north. Northern Armagh district is the main fruit-growing region on the island of Ireland, and the villages of Richhill and Loughgall are market centres for apples and strawberries. Light industrial centres include Keady, Laurelvale, and Tanderagee in addition to Armagh city. Most of the formerly important linen mills in the district have closed or diversified into the production of synthetic fibres. Southern Armagh district and adjacent areas near the Irish Republic's border were continuing hotbeds of sectarian violence during the late 20th century. Pop. (1981) city, 12,700; (1987 est.) district, 50,700.

Armagnac, historic region of southwestern France, now contained in the *département* of Gers. It is a region of hills reaching a height of 1,000 feet (300 m) and is drained by the Gers and other rivers, which descend fanwise from the Lannemezan Plateau. On the slopes of its hills grow the grapes from which the well-known Armagnac brandy is made.

A part of the duchy of Gascony in Merovingian and Carolingian times, Armagnac became a political unit during the feudal breakdown of the 10th century. From the 12th century on it gained strategic importance as a buffer

zone between lands controlled by the kings of France (Toulouse) and those controlled by the kings of England (Guyenne). Its counts used their position to shift allegiance and became highly independent. The Treaty of Calais (1360) during the Hundred Years' War (1337–1453) gave suzerainty over Armagnac to the English; an appeal by the Armagnac count Jean I against English rule (1368) gave Charles V of France a pretext to resume that war.

During the 14th century the counts of Armagnac greatly increased their holdings. By the beginning of the 15th century, their lands reached from the Garonne River to the Pyrenees and also included parts of the Massif Central.

The position of his holdings, along with the services of Gascon mercenaries, made it possible for Count Bernard VII to play a major role in France's internal conflicts of the early 15th century. The Armagnac party was formed in opposition to the Burgundians as a result of the murder of Louis, Duke d'Orléans (brother of the mad king Charles VI), by John the Fearless, duke of Burgundy (1407). With the marriage of his daughter to the son of the victim, Bernard came to head what had been the Orleanist party. Because the Burgundians often aligned with the English, the Armagnacs seemed to be a national party but were basically a power-seeking group. They gained control of the mad king from 1413. Bernard was named constable, chief of the army, and governor of all finances. The Armagnacs led the resistance to the English king Henry V's invasion of France but suffered a setback in the Battle of Agincourt (1415). Profiting from discontent caused by the harsh government of the Armagnacs, the Burgundians entered Paris and killed Bernard and many of his followers in the summer of 1418. After 1418 the Armagnacs rapidly lost power as the new king Charles VII gained leadership and was reconciled with Charles the Bold, duke of Burgundy.

The counts gradually lost their regional position. In 1473 a royal army captured their capital of Lectoure, and Count John V was killed. On the death of his brother Charles in 1497, the countship was united to the crown of France by Charles VIII. Francis I of France, however, bestowed it upon another Charles (nephew of the last count) and at the same time gave him his sister Margaret in marriage. After the death of her husband, by whom she had no children, Margaret married Henry II of Navarre; and thus the countship of Armagnac came back to the French crown along with the other dominions of their grandson, who became king of France as Henry IV (1607). During the 17th and 18th centuries, Armagnac existed as an administrative division of the *gouvernement-général* of Guyenne-et-Gascogne.

Armah, Ayi Kwei (b. 1939, Takoradi, Gold Coast [now Ghana]), Ghanaian novelist whose work deals with corruption and materialism in contemporary Africa.

Armah was educated in local mission schools and at Achimota College before going to the United States in 1959 to complete his secondary education at Groton School and his bachelor's degree at Harvard University. He thereafter worked as a scriptwriter, translator, and English teacher in Paris, Tanzania, Lesotho, Senegal, and the United States, among other places.

In his first novel, *The Beautiful Ones Are Not Yet Born* (1968), Armah showed his deep concern for greed and political corruption in a newly independent African nation. In his second novel, *Fragments* (1970), a young Ghanaian returns home after living in the United

States and is disillusioned by the Western-inspired materialism and moral decay that he sees around him. The theme of return and disillusionment continued in *Why Are We So Blest?* (1971), but with a somewhat wider scope. In *Two Thousand Seasons* (1973) Armah borrowed language from the African dirge and praise song to produce a chronicle of the African past, which is portrayed as having a certain romantic perfection before being destroyed by Arab and European despoilers.

All of Armah's works were concerned with the widening moral and spiritual chasm that existed between appearance and reality, spirit and substance, and past and present in his native Ghana.

Armalite rifle, any of several lightweight, small-calibre assault rifles designed by the American manufacturer Armalite, Inc. The first Armalite rifle, the AR-10, was a 7.62-millimetre, gas-operated weapon with a length of 40.5 inches (102.9 cm) and a weight of 8.8 pounds (4.0 kg). It did not survive its trials but did pave the way for highly successful, similar designs, notably the AR-15, the U.S. Army rifle designated as the M16 (*q.v.*). The British firm of Sterling Armament Company, Ltd., produces a Sterling-Armalite AR-18 rifle that resembles and operates like the AR-15, but that was carefully redesigned to be easily manufactured with unsophisticated equipment in less-developed countries—although no such arrangement was actually made.

Armani, Giorgio (b. July 11, 1934, Piacenza, Italy), Italian fashion designer whose signature style of relaxed yet luxurious ready-to-wear and elegant, intricately beaded evening wear helped introduce ease and streamlined modernity to late 20th-century dressing.

The son of a shipping manager, Armani intended to become a doctor but left medical school to pursue a career in fashion. Beginning in 1957 he worked as a buyer for the Milan department store La Rinascente. After a seven-year stint in that position, he began to pursue a career in fashion design, training in the atelier of Nino Cerruti. In 1975, with the help of his friend and business partner Sergio Galeotti, Armani launched his own label of ready-to-wear for men and women.

Armani best described his approach to fashion as follows: "I was the first to soften the image of men, and harden the image of women. I dressed men in women's fabrics, and stole from men what women wanted and needed—the power suit." His androgynous approach rarely disappointed fashion critics, who dutifully appeared each season at shows staged at his 17th-century palazzo on Via Borgonuovo in central Milan. Armani's reputation grew as a result of the popular film *American Gigolo* (1980), in which actor Richard Gere was featured as the dashing owner of a closetful of tailored Armani clothing. The public developed an increasingly insatiable demand for his minimalist style, and many Hollywood leading ladies became torchbearers for the Armani look at the Academy Awards ceremonies.

Over the years Armani continually added new offerings to his company—introducing perfume, accessories, a jeans line, the lower-priced diffusion line Emporio Armani, sportswear, and a limited-edition line of handmade couture dresses. In 2000–01 the Solomon R. Guggenheim Museum in New York City honoured Armani with a major retrospective of his work.

Armant (town, Egypt): *see* Hermonthis.

armatole, Greek ARMATOLOS, plural ARMATOLOI, any of the Greeks who discharged certain military and police duties under Ottoman authority in districts known as *armatoliks*. This police organization had its origins in Byzantine times, when *armatolismos* was a form of feudalism under which military and

police duties were rendered in return for a title to land. When the Ottoman Turks conquered Greece in the 15th century, they made treaties with the local *armatoles*, allowing them to continue in their police functions. Other Greeks, taking to the mountains, became unofficial, self-appointed *armatoles* and were known as *klephts* (from the Greek *kleptes*, "brigand"). These *klephts* might sometimes be recognized by the Turkish authorities as *armatoles*, while the *armatoles* who were out of favour continued as *klephts*. The two terms came to be used indiscriminately. Both *armatoles* and *klephts* played important roles in the War of Greek Independence (1821–32).

Armavir, city, Krasnodar *kray* (region), southwestern Russia. It lies along the left bank of the Kuban River. Founded in 1839, Armavir became a town in 1914. It is a rail junction on the line from Rostov-na-Donu to Baku. A branch line runs southwestward from Armavir to the Black Sea coast at Tuapse. Good communications and a rich surrounding agricultural area led to the growth of food-processing industries in Armavir, including one of the largest meat-packing combines in Russia. There is also a wide range of machine-building and timber-working industries in the city. Natural gas is obtained nearby. Pop. (1991 est.) 178,300.

Armco Inc., formerly (1948–78) ARMCO STEEL CORPORATION, or (1899–1948) AMERICAN ROLLING MILL COMPANY, American corporation first incorporated, as the American Rolling Mill Company, on Dec. 2, 1899. It was newly incorporated on June 29, 1917, and was subsequently renamed (using an acronym of the original) in 1948 and 1978 to reflect its diversified interests. Headquarters are in Middletown, Ohio.

Originally a manufacturer of sheet iron and steel, the company diversified, and its activities now include the manufacture of steel mill products, including such support activities as the mining of iron and coal and the extraction of gas, oil, and other fuels; the fabrication of metal products; and the production of metal and plastic industrial equipment and materials, with related engineering and construction services and sales. Although most of the company's products and services originate in the United States, the sale of products by foreign subsidiaries has been substantial.

The company was founded by a group of investors led by George Matthew Verity (1865–1942), the company's president until 1930 and thereafter chairman of the board. The company's first steel mill, at Middletown, was completed in January 1901, and production started in February. In 1905 the company bought a second plant, in Zanesville, Ohio, and in 1914 began its first foreign plant operation, in Brazil. The company began to diversify in 1969 with the purchase of Hitco, a California-based manufacturer of plastics and other nonmetallic materials.

Armenia, in full REPUBLIC OF ARMENIA, Armenian HAYASTAN, or HAYASTANI HANRAPETUT'YUN, country of Transcaucasia, formerly a union republic of the Soviet Union, successor to a historical region in southwestern Asia. Historical Armenia's boundaries have varied considerably, but old Armenia extended over what is now the northeastern part of Turkey and the Republic of Armenia. The latter is the smallest of the three Transcaucasian states (Georgia, Azerbaijan, Armenia). Turkish Armenia, unlike the Armenian republic, has no political designation, and it has only a small proportion of the region's Arme-

nian population, most of whom live in the Republic of Armenia. To the north and east, the Republic of Armenia is bounded by Georgia and Azerbaijan, to the west by Turkey, and to the southeast by Iran. Naxçıvan, an exclave of Azerbaijan, borders Armenia to the southwest. The capital of Armenia is Yerevan. Area 11,500 square miles (29,800 square km). Pop. (2003 est.) 3,061,000.

A brief treatment of Armenia follows. For full treatment, see MACROPAEDIA: Transcaucasia.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

Physical and human geography. The republic is a mountainous country with an average elevation of 5,900 feet (1,800 m) above sea level. The ranges of the Lesser Caucasus lie across its northern portion, and Lake Sevan (525 square miles [1,360 square km]) is located in the east-central part of the country. Armenia has a dry and continental climate that changes drastically with elevation. The lower semidesert portions of the country support drought-resistant plants, such as juniper, sloe, dog rose, and honeysuckle, and the extensive steppes are covered with grasses. The mountain slopes are overgrown with thorny bushes and juniper, and high meadows provide good summer pasture. The forests in the northeast are largely beech, and those in the southeast are mostly oak. Armenia's plains and foothills are sufficiently warm to permit cultivation of figs, pomegranates, peaches, and grapes. Higher up, tobacco, cereals, and some fruits are raised, and grain crops, potatoes, and fodder grasses are found up to 8,000 feet (2,400 m).

Armenians constitute more than nine-tenths of the country's population. There are also small numbers of Azerbaijanis, Kurds, Russians, Ukrainians, and other nationalities.

Armenia is increasingly urbanized and highly industrialized, though agriculture remains important to its economy. From its former status as a supplier of farm goods, copper, and brandy, Armenia has become a producer of chemicals, nonferrous metals, machinery, precision instruments, textiles, clothing, leather footwear, wines, and canned goods. Agriculture still engages a sizable portion of the population. Wine grapes are the most important crop. There are also orchard crops, potatoes and other vegetables, cotton, sugar beets, and livestock (sheep and cattle).

Mountainous terrain has made transportation difficult, but Armenia is served by railways and a dense network of motor roads. The hydroelectric potential of the mountain streams was a major factor in the republic's industrialization during the period of Soviet rule in the second half of the 20th century.

According to the constitution of 1995, the president, who is directly elected by popular vote, appoints the Council of Ministers (Cabinet) and its head, who serves as prime minister. Legislative authority rests with the elected members of the National Assembly. Education is compulsory and free of charge, and eight-year schooling has become the standard in Armenia. Among the establishments of higher learning is Yerevan State University (1919).

Armenian written literature began in the 5th century AD. The love songs of Sayat-Nova (d. 1795) are still popular. The musical works of the modern Armenian composer Aram Khachaturian are known throughout the world, and the paintings of the Armenian-born artist Arshile Gorky are famous. Among the cultural institutions in Armenia are the State Academic Theatre of Opera and Ballet, several drama theatres, symphony orchestras, and the Yerevan Film Studio. Carpet weaving and other traditional arts also flourish.

History. In ancient times Armenia was once powerful enough to challenge the Roman Em-

pire, but its subsequent history was marked by many struggles for independence and by the domination of many foreign powers.

The foundations of Armenian civilization were laid in the 6th century BC on the ruins of Urartu, an ancient kingdom that had been overrun by Scythians and Cimmerians in the wake of the conquest of Urartu's powerful ally, Assyria, by Babylonia and Media. Traces of Urartian civilization, particularly agricultural innovations, were probably extant when the Armenians—who called themselves the Hayq—moved into the area. The new

Armenia

occupants were quickly drawn into the Median empire, which in about 550 BC became a province of Persia's Achaemenian Empire. Local government was administered by village officials who paid tribute to the Persian king. In 331 BC Armenia was overrun by Alexander the Great, and in 301 it became part of the Seleucid empire.

With Rome's conquest of the Seleucids in 190–189, Armenia was divided into two provinces, Greater Armenia and Sophene, and reunification of these did not take place until the reign of the Armenian king Tigranes II the Great (95–55 BC). Under his rule Armenia reached the height of its power. It brought under its dominion the neighbouring regions of Albania and Atropatene (both now in Azerbaijan), Syria, and part of Parthia. Armenia was briefly the strongest state in the Roman East. In 66 BC, however, Tigranes was forced to cede territory and form an alliance with Rome, and Armenia subsequently became the focus of Roman and Parthian-Persian rivalry that lasted until the 3rd century AD.

By converting the Arsacid king Tiridates III to Christianity, St. Gregory the Illuminator brought about Armenia's permanent break from Persia and the East; Christianity was made the official religion of the Armenian state in AD 300. In about 390 the country was divided into Byzantine Armenia, which soon became part of the Byzantine Empire, and Persian Armenia, which remained under Persian suzerainty. As Persian power declined, Armenia was drawn into the Byzantine orbit. In 653 it came under Arab rule but was able to retain virtual autonomy.

The annexation of Armenia by the briefly revived Byzantine Empire in the 11th century was followed by the invasions of the Seljuq Turks, and the last quarter of the 11th century found the greater part of the country under Turkish domination. In the 13th century Armenia, much of which was at that time part of Georgia, was overrun by the Mongols. An Armenian migration into Cilicia following the Seljuq conquest had created the state of Little Armenia, which in the period of the Crusades became firmly allied to the West and absorbed much Frankish culture. During the 13th century Little Armenian rulers employed Mongol forces to assist them in warding off invasions

from Syria by the Egyptian Mamlūks, but the fall of the Little Armenian capital in 1375 brought the independence of the Armenian state to a close.

From the beginning of the 16th century, Armenia was once more the object of contention between two hostile nations, this time the Ottoman Empire and Iran, a situation that continued—with a brief interlude of Armenian independence (1722–30)—through the 18th century. During this time the country became a trade link between the East and Europe.

The advance of Russia into the Caucasus early in the 19th century inspired a renewal of Armenian culture and initiated foreign concern over the situation of Armenians under Ottoman Turkish rule. Following the Russo-Turkish War of 1877–78 and the Treaty of San Stefano, the issue grew into the "Armenian question." But attempts to effect reforms resulted only in a series of Turkish and Russian massacres of the Armenian populace. In 1915, during World War I, the Ottoman government ordered about 1,750,000 Armenians deported to Syria and Mesopotamia. Some 600,000 died in the desert en route. (See Armenian massacres.)

Following a Russian conquest in 1916, Armenia, with Georgia and Azerbaijan, formed a Transcaucasian alliance; within a few months the alliance was dissolved. A series of political upheavals, including the brief appearance of an independent Armenian republic in 1920, eventually led to the reunion of the three states as the Transcaucasian Soviet Federated Socialist Republic, which was incorporated into the Soviet Union in 1922. In 1936 the new Soviet constitution gave Armenia the status of a republic of the U.S.S.R. In the late 1980s and early '90s Soviet Armenia experienced ethnic unrest over the disputed political status of Nagorno-Karabakh, a mountainous region that was governed by the neighbouring Azerbaijan S.S.R. even though the majority of its population was Armenian. Northwestern Armenia was devastated on Dec. 7, 1988, by a massive earthquake that leveled the cities of Leninakan (now Gyumri) and Spitak and killed about 25,000 people. Armenia declared its independence from the collapsing Soviet Union on Aug. 23, 1990. In the years that followed, Armenia successfully fought Azerbaijan for control of the exclave of Nagorno-Karabakh until a cease-fire agreement was reached between the two countries in 1994.

Armenia, city, capital of Quindío *departamento*, west-central Colombia. It lies on the western slopes of the Cordillera Central at an elevation of 4,865 feet (1,483 m), between the Espejo and Quindío rivers. The city lies along a spur of the railway from Puerto Berrio to Popayán and is the transfer point for road traffic to Bogotá via Ibagué (30 miles [50 km] southeast). Armenia (named for the ancient kingdom) was founded in 1889 by Jesús María Ocampo and Antonio Herrera. Coffee, corn (maize), beans, sugarcane, silk, and plantains are marketed, and there is some light manufacturing. Coal deposits are nearby. Armenia is the seat of the University of Quindío (1960). Pop. (2003 prelim.) 303,939.

Armenia Minor: see Little Armenia.

Armenian, Armenian HAY, plural HAYQ, or HAYK, member of a people with an ancient culture who originally lived in the region known as Armenia, which comprised what is now northeastern Turkey and the Republic of Armenia. Although some remain in Turkey, more than three million Armenians live in the republic; large numbers also live in Azerbaijan, Georgia, and other areas of the Caucasus and the Middle East. Many other Armenians have migrated to Europe and North America.

The Armenians are the descendants of a branch of the Indo-Europeans. The ancient Greek historians Herodotus and Eudoxus of Rhodes related the Armenians to the Phrygians—who entered Asia Minor from Thrace—and to the peoples of the ancient kingdom upon whom the Phrygians imposed their rule and language. Known to the Persians as *Armina* and to the Greeks as *Armenioi*, the Armenian people call themselves *Hayq* (singular: *Hay*) and their country *Hayastan*, and they look back to a folk hero, *Hayk*.

The Armenian language is Indo-European, but the phonetics and grammar have some features in common with the Caucasian languages. The Armenians are traditionally members of either the Monophysite Armenian Apostolic (Orthodox) Church or the Armenian Catholic branch of the Roman Catholic church.

Until the early 20th century, the Armenians were primarily an agricultural people. From 1930 to 1990, however, considerable industrial development took place in the Armenian S.S.R., and by the late 20th century, two-thirds of the population of the republic, which is about nine-tenths Armenian, had become urbanized. This urban trend has also predominated among Armenians who have migrated to Europe and North America.

The ancient Armenian culture found expression in architecture, painting, and sculpture. The periods of greatest artistic activity tended to correspond to those of national independence or semi-independence, but, for the most part, this activity had reached its high point by the end of the 14th century. Armenian literature continued to develop after that period and witnessed a strong revival during the 19th century in the face of Turkish and Russian domination. Armenian writers did much to awaken the national consciousness of the Armenians, who became increasingly impatient with foreign rule. Growing nationalism on the part of Armenians provoked massacres by the Turks and confiscations by the Russians. The greatest single disaster occurred with the outbreak of World War I. In 1915 the Turks, regarding the Armenians as a dangerous foreign element, decided to deport the entire Armenian population of about 1,750,000 to Syria and Mesopotamia. An estimated 600,000 died of starvation or were killed en route. (See also Armenian massacres.) About one-third escaped deportation.

Armenian alphabet, script developed for the Armenian language in the 5th century AD and still in use. It was probably derived from the Pahlavi alphabet of Persia, with some Greek influences. According to local tradition, the Armenian alphabet was invented in the early 5th century AD by Mesrop Mashtots, aided by Isaac (Sahak) the Great, supreme head of the Armenian Apostolic Church, and by a Greek called Rufanos. Isaac founded a school of translators and had the Bible translated into Armenian in the new script. The oldest surviving documents in Armenian date from the 9th–10th century AD.

The Armenian script is a system of 38 letters—31 consonants and 7 vowels—well-adapted to the requirements of the Armenian language. Although it was probably patterned after the Pahlavi script, which was itself a descendant of the Aramaic alphabet, Armenian script shows distinct Greek influence by the presence of letters for vowels and in the direction of writing (from left to right). As a means of stabilizing and formalizing Armenian speech, it facilitated the unity of the Armenian nation and church.

Armenian Apostolic Church, the Orthodox national church of Armenia. Its claim to the title Apostolic is based on the belief

that Armenia was evangelized by the Apostles Bartholomew and Thaddaeus.

Christianity became the state religion of Armenia about AD 300, when St. Gregory the Illuminator converted the Arsacid king Tiridates III. The new Armenian church soon struck a course independent of the founding church at Caesarea Cappadociae (now Kayseri, Turkey), though it developed in close relationship with the Syrians, who provided it with scriptures and liturgy and much of its basic institutional terminology. Its dependence on the Syriac alphabet was ended in the 5th century, when Mesrop Mashtots invented an Armenian alphabet and carried out numerous translations of the Scriptures into Armenian.

In 506 at the Council of Dvin, the Armenian church rejected the ruling of the Council of Chalcedon (451) that the one Person of Christ consists of two natures; the Armenian church thus became (and remained) Monophysite (a view holding that Christ had only "one nature"). When the Georgian church broke away from the Armenians and reunited with the Greek Orthodox Church in the early 7th century, the Armenians remained in communion with the Coptic and Syrian Jacobite churches, confessing the Christological formula of St. Cyril of Alexandria, "one incarnate nature of the Word."

Gregory the Illuminator and his early successors had their residence at Ejmiadzin. It was moved to Dvin from 485 to 927, then was located variously until 1293, when the catholicate (highest ecclesiastical administrative office) was transferred to the Cilician capital, Sis (now Kozan, Turkey), where it remained after the fall of Cilicia to the Muslim Mamluks of Egypt. In the 15th century Gregory IX Musabegian rejected efforts to transfer the see to East Armenia in order to withdraw it from Roman influence. A synod of 17 bishops deposed him, and the monk Kirakos was elected catholicos at Ejmiadzin in 1441, initiating a long line of prelates bearing the title "Catholicos of All Armenians."

Owing to this history of inner dissension, the organization of the Armenian Apostolic Church is complex. There are two catholicoses: the supreme catholicos of all Armenians, residing at Ejmiadzin, and the catholicos of Sis, now residing at Antilyās, Lebanon; and two patriarchs, of Constantinople (now Istanbul, Turkey) and Jerusalem. The catholicos at Ejmiadzin is generally recognized as head of the whole church, the catholicos at Sis owing him spiritual allegiance, though retaining administrative autonomy. Relationships between the catholicates have on occasion been strained by political tensions. Whereas the supreme catholicos resides in Armenia, Armenian nationalists (*Dashnaks*) tend to support the see of Antilyās. This division is reflected among North American Armenians.

The two Armenian patriarchates of Constantinople and Jerusalem are of relatively recent origin and recognize the supremacy of Ejmiadzin. The patriarchate of Jerusalem was founded early in the 14th century when the monastery of St. James in Jerusalem proclaimed its bishop Sargis an independent patriarch. The patriarchate of Constantinople was created in 1461 by the Ottoman sultan Mehmed II, who appointed a local bishop to be the religious leader of the entire Armenian community in the Ottoman Empire. Because the territory involved included the majority of Armenians, the patriarch of Constantinople, while owing spiritual allegiance to Ejmiadzin, was effectively the most powerful prelate in the Armenian church until the end of the Ottoman Empire after World War I.

The Armenian Apostolic Church generally shares the doctrinal beliefs of the Eastern Orthodox church, except on the Monophysite question, and retains traditional Armenian rites. It is seen by many as the custodian of Armenian national identity.

Armenian Catholic Church, an Eastern-rite member of the Roman Catholic church. The Armenians embraced Christianity about AD 300 and were the first people to do so as a nation. About 50 years after the Council of Chalcedon (451), the Armenians repudiated the Christological decisions of the council and became the Armenian Apostolic (Orthodox) Church, a body that basically adhered to the doctrinal beliefs of Eastern Orthodoxy. There were Armenian Catholics, however, as early as the 12th century among the Armenians who fled from Muslim oppressors and established the kingdom of Little Armenia in Cilicia. Although the kingdom collapsed in 1375, Armenian Catholic monks, known as the Friars of Unity of St. Gregory the Illuminator, laid the groundwork for the future Armenian Catholic Church under Dominican influence.

The church came into being in 1740, when the Armenian bishop of Aleppo, Abraham Artzivian, already a Catholic, was elected patriarch of Sis (now Kozan, Turkey), in Cilicia. In 1911 the Armenian Catholic Church was divided into 19 dioceses; but, during the persecution of the Armenians in Turkey (1915–18), several dioceses were abolished, and the faithful left for other countries. In 1928 the church's hierarchical organization was revised, and new episcopal sees were successively erected. The Armenian patriarch of Cilicia now resides in Beirut and personally administers that diocese. There exist further three archdioceses (Aleppo, Baghdad, and Istanbul), three dioceses (Alexandria, Esfahān, and Kamichlie, Syria), one apostolic exarchy (Paris), and two ordinariates (Athens, and Gherla, Romania). The head of the Armenian Catholics is called "Patriarch of the Catholic Armenians and Katholikos of Cilicia" and has always taken the name Peter. The liturgy continues to be celebrated in the classical Armenian language.

Armenian chant, vocal music of the Armenian Apostolic Church and the religious poetry that serves as its texts. Armenia was Christianized quite early by missionaries from Syria and Greek-speaking areas of the eastern Mediterranean and accepted Christianity as the state religion about AD 300. The development of a distinctive Armenian liturgy was influenced by various factors. Toward the end of the 4th century, the Armenian church proclaimed its independence from the archbishopric of Caesarea Cappadociae (now Kayseri, Turkey), in Asia Minor. The great Armenian scholar Mesrop Mashtots invented the Armenian alphabet about 401 and carried out important translations of religious literature from Syriac and Greek into Armenian. The introduction of the new alphabet stimulated a flourishing literature, an important part of which was religious poetry. The earliest preserved examples date from the 4th century.

In the 12th century the catholicos (patriarch) Nerses IV Shnorhali ("the Gracious") is credited with musical reforms of the chant. He is said to have simplified the texts of the religious poetry and the melodies of the chant, bringing it closer to the style of Armenian folk music. Nerses also wrote a number of *sharakan* (hymns). The final form of the collection of *Sharakan*, containing nearly 1,200 hymns, was obtained about 1300 and has apparently remained unchanged.

About 1820 an Armenian from Constantinople (now Istanbul), Baba Hampartsoum Limondjian, proposed another reform and modernization of the musical notation along the lines of the contemporary notational reform in the Greek church (which allowed more precise indication of pitch). In its present-day performance, Armenian chant consists of intricate melodies with great rhythmic variety, and the melodies use many intervals not found in European music.

According to a long-standing tradition, the

most reliable oral transmission of the chant occurs in the religious capital of Armenia, Ejmiadzin, and in a few isolated monasteries. An important centre for Armenian musical studies is the Armenian Catholic Monastery of San Lazzaro in Venice (founded 1717), where the traditional Armenian melodies are said to be fairly well preserved.

Armenian Highland, Russian ARMYANSKOYE NAGORYE, also spelled ARM'ANSKOJE NAGOR'JE, mountainous region of Transcaucasia. It lies mainly in Turkey, occupies all of Armenia, and includes southern Georgia, western Azerbaijan, and northwestern Iran. The highland covers almost 154,400 square miles (400,000 square km). The average elevation of the Armenian Highland is 5,000 to 6,500 feet (1,500 to 2,000 m), but several peaks exceed 14,000 feet (4,000 m). The highland is a segment of the Mediterranean alpine volcanic zone of folding and has a subtropical continental climate. It is rich in minerals including chromite, gold, and iron.

Armenian language, language that forms a separate branch of the Indo-European language family. (It was once erroneously considered a dialect of Iranian.) Armenian is the mother tongue of the Turkish Armenians and of the Armenians in Armenia and is also spoken by people in other parts of the former Soviet Union. Armenian emigrants and refugees have taken their language with them throughout Anatolia and the Middle East and from there to many European countries (especially Romania, Bulgaria, and France) and to the United States.

A brief treatment of the Armenian language follows. For full treatment, see MACROPAEDIA: Languages of the World: *Armenian language*.

Invaders from the north introduced Armenian into Transcaucasia, probably in the latter part of the 2nd millennium BC. These invaders occupied the eastern region of Anatolia near the shores of Lake Van (now in Turkey). By the 7th century BC the Armenian language seems to have replaced the tongues of the native population there.

In the early 5th century AD, the Armenian language began to be written down; an alphabet of 36 characters was invented, according to tradition, by the bishop Mesrop Mashtots about AD 401. With the later addition of two letters, the same alphabet is still used by Armenians throughout the world. Grabar, the written language of the 5th century (the golden age of Armenian culture), is traditionally said to be based on the dialect of Tarawn on Lake Van. The language of the literature from the 5th to the 8th century is homogeneous, but by the 9th century the influence of the spoken dialects is noticeable. The best-known Middle Armenian variety of Grabar is the 12th- and 13th-century court language of the Armenian kingdom in Cilicia. More or less corrupted versions of Grabar continued as the literary language until the middle of the 19th century.

In the 1800s, Armenian nationalists brought about a renewal of Armenian national consciousness, and, somewhat incidentally, a new literary language that was much closer to the spoken language. Two varieties of the Armenian language now prevail: East Armenian, now the official language of Armenia, which is based on the dialect spoken around Mount Ararat and the Armenian city of Yerevan; and West Armenian, which has its foundation in the dialect spoken around the Turkish city of Istanbul. The differences between these two written forms of Modern Armenian are slight and constitute no barrier to mutual intelligibility. The great variety of Armenian dialects, however, can cause difficulty in communication.

Phonetic developments in Armenian have radically changed the sound system of the Indo-European parent language. In particu-

lar, the pattern of the plosive consonants—the stops—has been reshuffled. In the central Armenian dialects, three series of stops are distinguished; in those of the periphery, these have been reduced to two. All Armenian dialects distinguish two types of *r*, one strongly trilled, one weakly trilled. Old Armenian also differentiated between two types of *l*, one of them neutral and the other velarized, that is, made by moving the back of the tongue nearer to the soft palate at the back of the mouth.

Both in the spoken dialects and in the two literary languages, a fairly complicated system of noun declension has been maintained. Characteristic of the changes in the Old Armenian verbal system is the general replacement of simple present-tense forms by periphrastic expressions. These are groups of words, including auxiliaries, that take the place of a single word that is capable of being inflected to show tense or some other feature. The dialects are classified according to the various types of periphrastic forms. In Old and Modern Armenian, the main tense distinction is that between present, aorist (without reference to completeness or duration of the action), and periphrastic perfect tenses. The old subjunctive, still extant in Classical Armenian, has been lost in the modern language. To express future time, Old Armenian used the subjunctive forms; Modern Armenian uses periphrastic expressions, as English does in the future forms "I shall go" and "he will work." Also characteristic of Modern Armenian is the importance of the passive forms of the verb and the emergence of a negative conjugation with differing forms for verbs in instances such as "I read" and "I don't read." Whereas Old Armenian was rather close to Ancient Greek in many respects, Modern Armenian is typologically much closer to Turkish. The vocabulary of the written languages is purely Armenian, being based almost exclusively on that of Grabar, with very few loanwords from neighbouring languages.

Armenian literature, body of writings in the Armenian language. There is evidence that a pagan oral literature existed in Armenia before the invention of the Armenian alphabet in the 5th century AD, but, owing to the zeal of the early Christian priests, little of this was preserved. For about a century after their conversion to Christianity (c. 300), the Armenians had to rely on Greek and Syriac versions of the Bible and other religious books. These languages were unintelligible to the common people, and to remedy this Mesrop Mashtots invented the Armenian alphabet (c. 401). The catholicos Isaac (Sahak) the Great and Mesrop formed a school of translators who were reputedly sent to Edessa and to Constantinople to procure and translate Syriac and Greek copies of important works into Armenian.

Much of the literary activity of the 5th century (the golden age of Armenian literature) was devoted to such translations. Original works, however, were not wanting, such as the histories of Eghishe and Ghazar of Pharp. The masterpiece of classical Armenian writing is the "Refutation of the Sects" by Eznik Koghbatsi. This was a polemical work, composed partly from Greek sources, in defense of orthodox Christian belief against—and thereby providing valuable information about—pagan Armenian superstitions, Iranian dualism, Greek philosophy, and the Marcionite heresy. Its pure classical style is unsurpassed in Armenian literature. The work of translating such authors as Saints John Chrysostom and Cyril of Alexandria continued in the 6th–8th century. The so-called Hellenistic (Yunaban) school produced excessively slavish translations from Greek grammatical, theological, and philosophical works, including those of Plato, Aristotle, and Philo of Alexandria.

In the 10th and 11th centuries, which witnessed the maturity of the independent

Bagratid kingdom of Armenia, the Artsruni kingdom of Vaspurakan, and the kingdom of Siuniq, Armenian literature, art, and architecture flourished more freely than at any time since the 5th century. The principal literary figure of the 10th century was St. Gregory Narekatzi, the first great Armenian poet, renowned for his mystic poems and hymns as well as for such prose works as the *Commentary on the Song of Songs*. Earlier in the same century, Thomas (Thovma) Artsruni wrote a *History of the House of Artsruni*, which, in spite of its family bias, is the chief source of information on the history of Armenia down to 936; an anonymous writer continued the work to 1121. The *History of Armenia* by the catholicos John VI Draskhanakertzi is of great value for its account of Arab relations with Armenia, for the author was himself an important participant in the later events he describes. At the turn of the 10th to the 11th century, Bishop Ukhtanes wrote a *History of Armenia* and a *History of the Schism Between the Georgians and Armenians*. The beginning of the 11th century saw the completion of the reliable and well-written *Universal History* of Stephanos Asoghik. The *History of Armenia* by Aristakes Lastivertzi, relating the fall of the Bagratid kingdom (1045), the destruction of Ani (1064), and the victories of the Seljuq Turks, is almost as much a prose elegy as a history.

After the political collapse of Greater Armenia (c. 1100) and the consequent shift southward of the cultural centre to Little, or Cilician, Armenia, the literature split into a western and an eastern branch. In both branches authors began to write in the spoken as well as the classical language. The Mamluk invasion of 1375 and the invasion by Timur (Tamerlane) in 1385 ushered in a long period of cultural and literary decline.

There were signs in the 17th century that the Armenians were emerging from the cultural decline of the preceding centuries. The deeds of Turkish and Persian overlords figured prominently in histories by Araquel of Tabriz and Zaqaria the Deacon, but there was some contact with Western scholars and works in Latin. Oskan of Erevan (born in 1614 in the newly founded trading colony of New Julfa, Eşfahān) collaborated with the Dominican Pirandelli and printed the first Armenian Bible in Amsterdam in 1666. From the 13th century, imaginative writing had been represented by a succession of popular troubadours, the most famous of these being Nahapet Kuchak (16th century), one of the rare Armenian poets to sing of physical love; Hovnatan Naghash (1661–1722); and in the following century, most famous of all, Aruthin Sayadian, called Sayat-Nova.

The 18th century witnessed an Armenian cultural and intellectual renaissance, and, by the middle of the 19th century, the time was ripe for the development of a modern Armenian literature. The Armenian language, however, was in a chaotic state, and the question of which form should serve as the vehicle for new ideas led to controversies, both in Turkish and Russian Armenia, between champions of the old classical language and those of the modern spoken languages. Eventually the latter prevailed, with the result that from that point on the eastern literature was written in a modified form of the Yerevan dialect (*nusahayeren*) and that of the west in a modified form of the dialect of Istanbul (*dachgahayeren*). For their models, and for many of their ideals, Armenian writers looked to Europe. Among western authors, Hakob Paronian and Ervand Otian were outstanding satirical novelists, and Grigor Zohrab wrote realistic short stories; the theatre was best represented by Paronian, whose comedies (as *The Dowry*,

Master Balthazar, The Oriental Dentist) still remain popular.

The novel, weak in western Armenian literature, was strongly represented in Russian Armenia, where it became a vehicle for Armenian moral, social, and political aspirations. Khachatur Abovean, the "father of modern Armenian literature," wrote *Wounds of Armenia* in 1841. The most celebrated Armenian novelist was Hakob Meliq-Hakobian, or Raffi. Among eastern poets, Hovhannes Thumanian wrote lyric and narrative poems; and his masterpiece, a short epic, *Amush*, full of songs that have become traditional, was early adapted as an opera. The most outstanding Armenian dramatist was Gabriel Sundukian, whose comedies (*Hullabaloo* [also called *Khatabala*], *Pepo*, *The Broken Heart*) portrayed the contemporary Armenian society of T'bilisi, in whose dialect most of them were written.

The rapid decline of Istanbul as the principal western Armenian literary centre (after the Armenian massacres of 1915–16) brought about a new period of decline in Armenian literature, although Armenians scattered abroad continued to write in Paris, Beirut, and Boston. Some Turkish Armenians fled to the east, where they enjoyed a certain degree of autonomy and where, between 1936 and 1991, national literature was encouraged but controlled by the Soviet state.

Armenian massacres, series of brutal campaigns conducted against the Armenian subjects of the Ottoman Empire by Sultan Abdülhamid II in 1894–96 and by the Young Turk government in 1915–16.

It is estimated that nearly two million Christian Armenians lived in the Ottoman Empire by the late 1880s. The Armenians in the eastern provinces at that time, encouraged by Russia, began promoting Armenian territorial autonomy. As the movement grew, various political groups were organized, culminating in the formation of two revolutionary parties called Hēnchak ("The Bell") and Dashnaktsutyun ("Union") in 1887 and 1890, respectively. At the same time, Abdülhamid, intent on suppressing all separatist sentiments in the empire, drastically raised taxes on the Armenians and aroused nationalistic feelings and resentment against them among the neighbouring Kurds. This gave Armenian radicals a pretext to revolt. When the Armenians in Sasun refused to pay the oppressive taxes, Turkish troops and Kurdish tribesmen killed thousands of them and burned their villages (1894).

In the hope of calling attention to their cause, Armenian revolutionaries staged another demonstration two years later: they seized the Ottoman Bank in Istanbul. In the mayhem that followed, more than 50,000 Armenians were killed by mobs of Muslim Turks, whose actions were apparently coordinated by government troops.

The last and deadliest of the massacres occurred during World War I (1914–18). Armenians from the Caucasus region of the Russian Empire formed volunteer battalions to help the Russian army against the Turks. Early in 1915 these battalions recruited Turkish Armenians from behind the Turkish lines. In response, the Turkish government ordered the deportation of about 1,750,000 Armenians to Syria and Mesopotamia. In the course of this forced exodus, about 600,000 Armenians died of starvation or were killed by Turkish soldiers and police while en route in the desert. Hundreds of thousands more were forced into exile.

Armenian rite, the system of liturgical practices and discipline observed by both the Armenian Apostolic (Orthodox) Church and the Armenian Catholics. The Armenians, who re-

gard themselves as the "first Christian nation," were converted to Christianity by St. Gregory the Illuminator about AD 300. The Liturgy of St. Gregory the Illuminator, used by both Apostolic and Catholic Armenians, is patterned after the Antiochene Liturgy of St. James and the Byzantine Liturgy of St. John Chrysostom and is usually divided into five parts: (1) the prayers of preparation in the sacristy, (2) the prayers of preparation in the sanctuary, (3) the preparation and consecration of the gifts, (4) the liturgy of the catechumens, and (5) the liturgy of the faithful, culminating in Communion.

Churches of the Armenian rite, unlike Byzantine churches, are generally devoid of icons and, in place of an iconostasis (screen), have a curtain that conceals the priest and the altar during parts of the liturgy. The Communion itself is given in two species, as in other Orthodox churches. For its worship services the Armenian rite is dependent upon such books as the *Donatzuitz*, the order of service, or celebration of the liturgy; the *Badarakamaduitz*, the book of the sacrament, containing all the prayers used by the priest; the *Giashotz*, the book of midday, containing the Epistle and Gospel readings for each day; and the *Z'amagirq*, the book of hours, containing the prayers and psalms of the seven daily offices, primarily matins, prime, and vespers.

Armentières, town, Nord *département*, Nord-Pas-de-Calais *région*, northern France. It lies along the Lys River, near the Belgian frontier. The town was entirely rebuilt after being destroyed in World War I, and its red brick buildings present a uniform appearance. Armentières was 2 miles (3 km) behind the battle line throughout most of World War I, and from April until October 1918 it was occupied by the Germans. During World War II the town was bombed and was again occupied by the Germans from May 1940 until September 1944.

Romans who were in the area in 57 BC raised cattle on the banks of the Lys. The name Armentières is derived from the Gallo-Roman *armentum*, meaning "cattle for ploughing" or, collectively, "herd." Since the Middle Ages, Armentières has been noted for its linen, but the industry has had difficulties in recent years. Printing is important, and other industries include dyes, clothing, beer, and machinery. Agriculture in the surrounding area is important, and flax was formerly one of the chief crops. Pop. (1999) 25,273.

Armfelt, Gustaf Mauritz (b. March 31, 1757, St. Mårtens, near Turku, Finland, Kingdom of Sweden [now in Finland]—d. Aug. 19, 1814, Tsarskoye Selo [now Pushkin], near St. Petersburg, Russia), Swedish statesman prominent in diplomacy and military affairs.

Appointed gentleman to Gustav III of Sweden in 1781, Armfelt was employed in the negotiations with Catherine II of Russia (1783) and with the Danish government (1787) and was one of the king's most trusted and active counselors during the war with Russia in 1788–90. In 1788, when the Danes invaded Sweden and threatened Göteborg, Armfelt, under the king's direction, organized the Dalarna levies. He remained faithful to Gustav when nearly all the nobility deserted him; and he was the Swedish plenipotentiary at the Peace of Värälä (1790).

On his deathbed in 1792, Gustav III entrusted his son to Armfelt and made him a member of the council of regency; but the duke-regent Charles (afterward Charles XIII) sent Armfelt as Swedish ambassador to Naples to get rid of him. From Naples Armfelt communicated with Catherine II, urging her to make a military demonstration in favour of the Gustavians. The plot was discovered by the regent's spies, and Armfelt escaped only with the help of Queen Caroline of Naples (1794). He then fled to Russia. When Gustav

IV Adolf attained his majority, Armfelt was rehabilitated and sent as Swedish ambassador to Vienna (1802), but he had to quit that post two years later for attacking the Austrian government's attitude toward Napoleon Bonaparte. From 1805 to 1807, he was commander in chief of the Swedish forces in Pomerania, where he retarded the French conquest.

Expelled from Sweden in 1811, Armfelt again found refuge in Russia, where he gained great influence over the emperor Alexander I. He contributed to the erection of the grand duchy of Finland as an autonomous state, and he participated in the planning of the Russian defensive campaigns against Napoleon.

Armidale, city, northeastern New South Wales, Australia. It lies on the valley slopes of Dumaresq Creek in the New England Range. Founded in 1839 by G.J. Macdonald, commissioner of crown lands, and named for his father's Scottish baronial estate on the Isle of Skye, it developed a pastoral-agricultural economy. It has become a regional cultural centre with Anglican and Roman Catholic cathedrals, a teachers' college, several private and state schools, and the University of New England (established 1954). The New England Regional Art Museum houses the Howard Hinton collection of Australian paintings. For many years the community has been the main focus of a movement for a separate New England State. It became a town in 1845, a municipality in 1863, and a city in 1885. The city is linked by rail with Sydney, 230 miles (370 km) south, and has an airport. Pop. (2001 prelim.) 24,875.

Armilaria, genus of about 40 species of fungi of the order Agaricales (*q.v.*), in the class Basidiomycetes, found throughout northern North America and Europe, principally in forests of hardwoods or mixed conifers. In suitable environments, members of this genus may live for hundreds of years, and certain specimens have been identified as among the largest and oldest living organisms.

From late summer to autumn, *Armilaria* species produce similar-looking mushrooms, or fruiting bodies, with notched gills extending part way down the stalk and a single or double ring near the base of the cap. The colour ranges from white to golden. Most species are found on the ground, but a few, including the honey mushroom (*A. mellea*), will grow directly on wood.

Armilaria grow from a single fertilized white spore and spread vegetatively through hyphae, threadlike filaments of cells that aggregate to form long, cordlike bundles called rhizomorphs. The rhizomorphs' underground growth may form an extensive network, or mat, as it spreads through the soil in search of nutrients from decaying wood or living tree roots. The rhizomorphs secrete enzymes that digest these foods, which are absorbed through the hyphal walls. Shielded underground, the hardy rhizomorph can withstand extremes of temperature, including aboveground forest fires.

Given suitable forest conditions, the fungal mat (mycelium) can reach extraordinary proportions. In 1992 a mat of *A. bulbosa* was identified in a mixed oak forest near Crystal Falls, in Michigan's Upper Peninsula. Genetic testing on sample mushrooms gathered throughout the area determined that all were produced by a single supporting mycelium that extended over more than 15 hectares (37 acres); its estimated total weight was more than 10,000 kg (220,000 pounds), and, based on calculations from known growth rates, it was thought to be at least 1,500 years old. Later that year, a specimen of *A. ostoyae* was identified on Mount Adams, in southwestern Washington state. Its age was estimated at 400 to 1,000 years, and it far exceeded the Michigan fungus in size, covering some 607 hectares (1,500 acres).

armillary sphere, early astronomical device for representing the great circles of the heavens, including in the most elaborate instruments the horizon, meridian, Equator, tropics, polar circles, and an ecliptic hoop. The sphere is a skeleton celestial globe, with circles divided into degrees for angular measurement. In the 17th and 18th centuries such models—either suspended, rested on a stand, or affixed to a handle—were used to show the difference between the Ptolemaic theory of a central Earth and the Copernican theory of a central Sun.

Armillary sphere from Thomas Blundeville's *Plaine Treatise . . . of Cosmographie*, 1594

By courtesy of the trustees of the British Museum photograph J.R. Freeman & Co Ltd

The earliest known complete armillary sphere with nine circles is believed to have been the *meteōroskopion* of the Alexandrine Greeks (c. AD 140), but earlier and simpler types of ring instruments were also in general use. Ptolemy, in the *Almagest*, enumerates at least three. It is stated that Hipparchus (146–127 BC) used a sphere of four rings; and in Ptolemy's instrument, the *astrolabon*, there were diametrically disposed tubes upon the graduated circles, the instrument being kept vertical by a plumb line.

The Arabs employed similar instruments with diametric sight rules, or alidades, and it is likely that those made and used in the 12th century by Moors in Spain were the prototypes of all later European armillary spheres.

Armilus, in Jewish legends, an enemy who will conquer Jerusalem and persecute Jews until his final defeat at the hands of God or the true Messiah. His inevitable destruction symbolizes the ultimate victory of good over evil in the messianic era. Some sources depict Armilus as partially deaf and partially maimed, the frightful offspring of Satan or evil creatures. Parallel legends exist in the figures of Antichrist and of Ahriman, the Persian god of evil.

Arminianism, a theological movement in Christianity, a liberal reaction to the Calvinist doctrine of predestination. The movement began early in the 17th century and asserted that God's sovereignty and man's free will are compatible.

The movement was named for Jacobus Arminius (q.v.), a Dutch Reformed theologian of the University of Leiden (1603–09), who became involved in a highly publicized debate with his colleague Franciscus Gomarus, a rigid Calvinist, concerning the Calvinist interpretation of the divine decrees respecting election and reprobation. For Arminius, God's will as unceasing love was the determinative initiator and arbiter of human destiny. The movement that became known as Arminianism, however, tended to be more liberal than Arminius.

Dutch Arminianism was originally articulated in the Remonstrance (1610), a theolog-

ical statement signed by 45 ministers and submitted to the Dutch states general. The Synod of Dort (1618–19) was called by the states general to pass upon the Remonstrance. The five points of the Remonstrance asserted that: (1) election (and condemnation on the day of judgment) was conditioned by the rational faith or nonfaith of man; (2) the Atonement, while qualitatively adequate for all men, was efficacious only for the man of faith; (3) unaided by the Holy Spirit, no person is able to respond to God's will; (4) grace is not irresistible; and (5) believers are able to resist sin but are not beyond the possibility of falling from grace. The crux of Remonstrant Arminianism lay in the assertion that human dignity requires an unimpaired freedom of the will.

The Dutch Remonstrants were condemned by the Synod of Dort and suffered political persecution for a time, but by 1630 they were legally tolerated. They have continued to assert effective liberalizing tendencies in Dutch Protestant theology.

In the 18th century, John Wesley was influenced by Arminianism. In *The Arminian Magazine*, edited by him, he stated that "God willeth all men to be saved, by speaking the truth in love." Arminianism was an important influence in Methodism, which developed out of the Wesleyan movement. A still more liberal version of Arminianism went into the making of American Unitarianism.

Arminius, German HERMANN (b. 18 BC?—d. AD 19). German tribal leader who inflicted a major defeat on Rome by destroying three legions under Publius Quinctilius Varus in the Teutoburg Forest (southeast of modern Bielefeld, Ger.), late in the summer of AD 9. This defeat severely checked the emperor Augustus' plans, the exact nature of which is uncertain, for the country between the Rhine and Elbe rivers.

Arminius, bust; in the Capitoline Museum, Rome

Alinari—Art Resource

Arminius was a chief of the Cherusci. In the service of the Romans he had obtained both citizenship and equestrian rank. Six years after the Teutoburg Forest Massacre, Germanicus Caesar engaged Arminius in battle, capturing his wife, Thusnelda, but in AD 16 Arminius skillfully survived a full-scale Roman attack. When Roman operations were suspended in 17, Arminius became involved in war with Maroboduus, king of the Marcomanni, and though successful he was subsequently murdered by his own people. The conception of Arminius as a German national hero reached its climax in the late 19th century. It could claim support from Tacitus' judgment of him as "unquestionably the liberator of Germany" (*liberator haud dubie Germaniae*); but it is clear that in Arminius' day a united "Germany" was not even an ideal.

Arminius, Jacobus, Dutch JACOB HARMENSEN or HERMANZ (b. Oct. 10, 1560, Oudewater, Neth.—d. Oct. 19, 1609, Leiden), theologian and minister of the Dutch

Reformed Church who opposed the strict Calvinist teaching on predestination and who developed his own system of belief known later as Arminianism.

His father died when Arminius was an infant, and one Theodore Aemilius adopted the child and provided for his schooling in Utrecht. On the death of Aemilius in 1575, Rudolf Snellius (Snel van Roijen, 1546–1613), a professor at Marburg and a native of Oudewater, became the patron for his further education at the universities of Leiden (1576–82), Basel, and Geneva (1582–86).

After brief stays at the University of Padua, in Rome, and in Geneva, Arminius returned to Amsterdam. He was ordained there in 1588. In 1603 Arminius was called to a theological professorship at Leiden, which he held until his death. These last six years of his life were dominated by theological controversy, in particular by his disputes with Franciscus Gomarus, his colleague at Leiden.

Considered a man of mild temperament, Arminius was forced into controversy against his own choice. He had earlier affirmed the Calvinist view of predestination, which held that those elected for salvation were chosen prior to Adam's fall, but he gradually came to have doubts. To him predestination seemed too harsh a position because it did not allow human decision a role in the achieving of salvation. Hence Arminius came to assert a conditional election, according to which God elects to life those who will respond in faith to the divine offer of salvation. In so doing, he meant to place greater emphasis on God's mercy.

After his death some of his followers gave support to his views by signing the *Remonstrance*, a theological dictum written by Johannes Uytenbogaert, a minister from Utrecht, in 1610. Remonstrant Arminianism was debated in 1618–19 at the Synod of Dort (Dordrecht), an assembly of the Dutch Reformed Church at which all the delegates were supporters of Gomarus. Arminianism was discredited and condemned by the synod, the Arminians present were expelled, and many others suffered persecution.

In 1629, however, the works of Arminius (*Opera theologica*) were published for the first time in Leiden, and by 1630 the Remonstrant Brotherhood had achieved legal toleration. It was finally recognized officially in the Netherlands in 1795. In its emphasis on the grace of God, Arminianism influenced the development of Methodism in England and the United States.

armistice, an agreement for the cessation of active hostilities between two or more belligerents. Generally, the terms, scope, and duration of an armistice are determined by the contracting belligerents. An armistice agreement may involve a partial or temporary cessation of hostilities—called a local armistice or truce—established for a variety of specific purposes, such as collecting the dead. Or it may involve a general armistice (i.e., a total cessation of all hostilities) such as the French armistice agreement of 1940. Although a total cessation may appear to be tantamount to a de facto termination of the war, it is not recognized as such legally. Under international law the state of war still exists and with it the rights and duties of the belligerents and of the neutral parties. Thus, unless otherwise agreed, the warring parties may continue to maintain a blockade and conduct visitations of neutral ships. The more recent trend has been to broaden the scope of the armistice to give it the form and substance of a preliminary peace treaty such as the armistice agreement signed on July 27, 1953, ending the hostilities in Korea.

The general rules regarding an armistice were formulated at the Hague Peace Conference of 1907 and are contained in the Hague land war regulations. According to the provisions of these regulations, hostilities can be resumed in an indefinite armistice as a result of proper notification or serious violation of the armistice. Acts that constitute a serious violation include a deliberate advance, seizure of any point outside a party's line, and withdrawal of troops from an unfavourable or weak position.

The Armistice of Nov. 11, 1918, ending World War I between Germany and the Allied powers, departed from the usual form (1) in being preceded by negotiations between the belligerents, resulting in a so-called "prearmistice" agreement and (2) in including political and financial clauses in addition to the military terms. Its military terms made the resumption of hostilities virtually impossible for Germany, thus precluding the usual option in armistices.

armlet, decorative band, usually of gold, silver, or other metal and sometimes featuring precious gems, worn for ornament around the arm, especially the upper arm. Armlets have been worn since ancient times: in Assyrian art, for instance, deities, monsters, and men are shown wearing armlets.

Several fine examples of armlets are included in the Oxus treasure, a collection of Persian art of the Achaemenid period (6th–4th century BC) now in the British Museum, London. One of the armlets consists of a circular gold band with its two ends meeting in the form of finely worked griffins. Armlets are especially popular in the East, particularly in India.

armoire, large cupboard, usually movable and containing shelves, hanging space, and sometimes drawers, and fitted with two doors. It was originally used for storing arms. The armoires designed by Andre-Charles Boulle, the cabinetmaker to Louis XIV in the late 17th century, are among the most sumptuous and imposing pieces of Western furniture.

The word, which sometimes denoted a cupboard set into the paneling of a room, was probably first used in the 16th century, when detailed carving based on Flemish design was characteristic of fine examples. In the following century geometric designs in high relief became more common; also, in the 17th century

the name was extended to cover wardrobes and clothespresses.

armor: see armour.

armorial ensign, flag with heraldic significance, distinguished by its shape and purpose. The principal armorial ensigns are the banner, the pennon, the guidon, the standard, and the pendant, or pennant.

Armorial ensigns
(Top) Banner of Haig of Bemersyde and (bottom) guidon of Mayster Compton

Originally, the banner was restricted to magnates—peers, feudal barons, and knights bannerets, for example. A square or rectangular flag bearing personal or family insignia, it was carried in action before such royal and noble warriors. Today this most cherished ensign of medieval times is generally used by all armigerous persons throughout Europe except in Scotland, where it is restricted to magnates.

The ensign used by simple knights was a small triangular flag called a pennon. Flown from the lance, the pennon was used to terrorize the enemy as well as to indicate rank. All armigerous persons below banneret's rank may use it. On the field of battle, when promotion to the rank of knight banneret was made, the points of the knight's pennon were cut off, to make it an improvised banner.

The guidon, a long, tapering flag, was the cavalry standard and was carried in battle by warriors below the rank of knight. In the hoist (the part nearest the staff to which the ensign was attached), the guidon usually had the national cross (St. George, St. Andrew, and so forth) and, in the fly (the part farthest from the staff), a principal (beast) badge, which, with the field, was in the livery colours.

The standard, half as long again as the guidon, was the largest form of armorial ensign and was intended to be stationary. It marked the carrier's position in battle, in a ceremony, or at a tournament. The flying of a standard often indicated the monarch's presence at a palace, castle, saluting base, or ship.

The pennant, or pendant, earlier called a streamer, was a long, tapering flag, 20–60 yards (18–55 m) long and 8 yards (7 m) wide, ending in two points. Used mainly at sea, it was flown in the 15th century from a pole rising above the fighting top and later from the yardarm or topmast. It came to distinguish the warship from the merchant ship. Hoisted when the captain assumes his command, the pennant indicates a warship in commission, as opposed to a warship laid up.

Armorica, also spelled **AREMORICA** (from Celtic *ar*, "on," and *mor*, "sea"), Latin name for the northwestern extremity of Gaul, now Brittany. In Celtic, Roman, and Frankish

times Armorica also included the western part of what later became Normandy. In Julius Caesar's time it was the home of five principal tribes, the most important being the Veneti. Under the Roman Empire it formed part of the province of Gallia Lugdunensis, but it was never thoroughly Romanized. It received many Celtic immigrants from the British Isles in the 5th century, during the time of the Saxon invasion.

Armorican Massif, French **MASSIF ARMORICAIN**, flattened erosional upland, or *penneplain*, encompassing the western French *départements* of Finistère, Côtes-d'Armor, Morbihan, and Ille-et-Vilaine and parts of Manche, Orne, Mayenne, Maine-et-Loire, Loire-Atlantique, and Vendée. The region has an area of approximately 25,000 square miles (65,000 square km) and is bounded by the Paris Basin and the Seine River to the north and by the lowlands of the Loire and its tributaries to the south. Crystalline schist from Precambrian Time (more than 570 million years old) predominates and is interlaced with bands of gneiss. Mountains formed during the Hercynian orogeny (mountain-building episode) of the Carboniferous Period (which occurred from 360 to 286 million years ago) have been largely worn down by erosion, and elevations rarely exceed 1,300 feet (400 m). The mountain of Avaloirs in Orne reaches an elevation of 1,368 feet (417 m) and is the highest point in the Armorican Massif. Uplands include the hills of Arrée in Finistère and Côtes-d'Armor and Mené in Côtes-d'Armor. The basin of Châteaulin occupies much of Finistère and is drained by the Aulne River; the basin of Rennes dominates Ille-et-Vilaine. Erosion has carved out sharp *abers*, or gorges, in the north. The coastline is deeply indented.

The Gauls referred to the coastline as Armor, the land of the sea; the interior was known as Arcoat, the land of forests. Much of the interior has been deforested. Animal husbandry dominates agriculture, and the region is a leading producer of milk, cheese, beef, and pork. The cultivation of fodder is increasing. Emigration from the countryside has resulted in the consolidation of farmland. The population is concentrated along the coast, which has grown at the expense of the hinterland.

Armory Show, formally **INTERNATIONAL EXHIBITION OF MODERN ART**, an exhibition of painting and sculpture held from Feb. 17 to March 15, 1913, at the Sixty-ninth Regiment Armory in New York City. The show, a decisive event in the development of American art, was originally conceived by its organizers, the Association of American Painters and Sculptors, as a selection of representational works exclusively by American artists, members both of the National Academy of Design and of the more progressive Ashcan School and The Eight. The election of Arthur B. Davies as president of the association changed this conception. A member of The Eight, Davies produced pleasant, Romantic paintings that enjoyed the respect of almost all of the American art establishment. He was also a man with a broad, highly developed taste, capable of appreciating trends in art far more radical than his own style, and he was aware of developments in Europe. Davies, with the help of Walt Kuhn and Walter Pach, spent a year, much of it in Europe, assembling a collection that was later called a "harbinger of universal anarchy." The exhibition traveled to New York City, Chicago, and Boston and was seen by approximately 300,000 Americans. Of the 1,600 works included in the show, about one-third were European, and attention became focused on them. The selection was almost a history of European Modernism. Beginning with J.-A.-D. Ingres and Eugène Delacroix, the exhibition displayed works by Impressionists, Symbolists, Postimpressionists, Fauves, and Cubists.

Although the sculpture section was weak and the Expressionists were poorly represented, the show exposed the American public for the first time to advanced European art. American art suffered by contrast.

Reactions to the show were varied. Marcel Duchamp's Cubist painting "Nude Descending a Staircase, No. 2" was popularly described as "an explosion in a shingle factory"; and Henri Matisse, Constantin Brancusi, and Walter Pach were hanged in effigy by Chicago art students. Yet this show became the basis of many important private American collections.

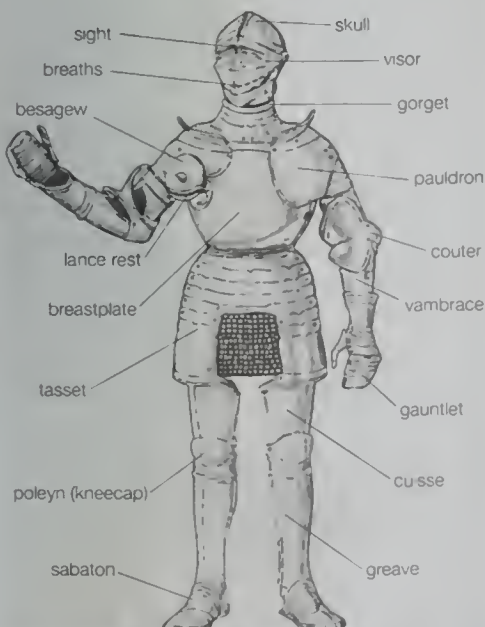

For American art, the show had results more difficult to gauge. Stuart Davis exemplified one artist's reaction: "The Armory Show was the greatest shock to me—the greatest single influence I have experienced in my work." Similarly, the artists Joseph Stella, John Marin, Georgia O'Keeffe, and Arthur Dove were encouraged by the Armory Show to continue their avant-garde direction. American painting in general, however, continued to be dominated by the realists—the Ashcan School and its successors, American Scene painting and Social Realism—until some 30 years later.

armour, also spelled **ARMOR**, also called **BODY ARMOUR**, protective clothing with the ability to deflect or absorb arrows, spears, lances, swords, bullets, or other weapons that may be used against its wearer in combat.

Types of armour generally fall into one of three main categories: (1) armour made of leather, fabric, or mixed layers of both, sometimes reinforced by quilting or felt, (2) mail, made of interwoven rings of iron or steel, and (3) rigid armour made of metal, horn, wood, plastic, or some other similar tough and resistant material. The third category includes the plate armour that protected the knights of the European Middle Ages. This armour was composed of large steel or iron plates that were linked by loosely closed rivets and by internal leathers to allow the wearer maximum freedom of movement.

Presumably the use of armour extends back beyond historical records, when primitive warriors protected themselves with leather hides and helmets. In the 11th century BC, Chinese warriors wore armour made of five to seven layers of rhinoceros skin, and ox hides were similarly used by the Mongols in the 13th century AD. Fabric armour, too, has a long history, with thick, multilayered linen cuirasses worn by the Greek heavy infantry of the 5th century BC and quilted linen coats worn in northern India until the 19th century.

The advantage of chain mail (*q.v.*) is that it

is quite flexible yet is relatively impervious to slashing strokes (though a thrusting weapon can force the rings apart in spite of their riveted closure). In the form of a simple shirt, mail was worn throughout the Roman Empire and beyond most of its frontiers, and mail formed the main armour of western Europe until the 14th century. In Europe, strips of mail were also worn underneath plate armour to close any gaps left between the rigid plates. Mail shirts were worn in India and Persia until the 19th century, and the Japanese used mail to a limited extent from the 14th century, though the rings in Japanese mail were arranged in a variety of ways, producing a more open construction than found in Europe. Mail sleeves, leg harnesses, and hoods have also been worn.

Armour made of rigid plates was used by the ancient Greeks and Romans and reappeared in Europe about the 13th century. Plate armour dominated European armour design until the 17th century, by which time the use of firearms had made body armour in general obsolete.

Ancient Greek infantry soldiers wore plate armour consisting of a cuirass (a piece of armour covering the body from neck to waist), long greaves (armour for the leg below the knee), and a deep helmet—all of bronze. The Roman legionary wore a cylindrical cuirass made up of four to seven horizontal hoops of steel, with openings at the front and back, where they were laced together. The cuirass was buckled to a throat piece that was in turn flanked by several vertical hoops protecting each shoulder. Apart from helmets, armour made of large plates was probably unknown in western Europe during the Middle Ages, and mail was the main defense of the body and limbs during the 12th and 13th centuries. Mail hoods covered the head and neck, and mail leggings covered the legs. Mail, however, did not possess the rigid glancing surface of plate armour, and, as soon as the latter could

be made responsive to the movements of the body by ingenious construction, it replaced mail. Thus plate armour of steel superseded mail during the 14th century, at first by local additions to knees, elbows, and shins, until eventually the complete covering of articulated plate was evolved. A complete suit of German armour from about 1510 shows a metal suit with flexible joints covering its wearer literally from head to toe, with only a slit for the eyes and small holes for breathing in a helmet of forged metal. (See the Figure.) The armour suits of royalty and aristocrats were often elaborately gilded, etched, and embossed with fine decoration.

In the 16th and 17th centuries, improvements in hand firearms forced armourers to increase the thickness and, therefore, the weight of their products, until finally plate armour was largely abandoned in favour of increased mobility. Armour cuirasses and helmets were still used in the 17th century, but plate armour disappeared completely in the 18th century, since it was by then useless against most firearms and only hampered the soldier's mobility. One basic piece of armour, however, the helmet (*q.v.*), reappeared on the battlefield during World War I and became a standard piece of equipment for most soldiers.

The principal purpose of modern body armour is to stop or deflect shell or grenade fragments and bullets. Some use was made of armoured clothing in World War II, but it was found to be too heavy for regular use in combat. Modern body armour uses small plates of alloy steel sewn or stapled into a garment that covers at least the chest and groin. The separately attached but overlapping steel plates give great freedom of movement as well as protection. Fibreglass, boron carbide, or numerous layers of nylon fabric sometimes replace the metal plates and tend to increase not only the protection but also the comfort of such garments. Modern body armour that covers the torso is called a bulletproof vest.

Armour, Philip Danforth (b. May 16, 1832, Stockbridge, N.Y., U.S.—d. Jan. 6, 1901, Chicago, Ill.), American entrepreneur and innovator whose extensive Armour & Company enterprises helped make Chicago the meat-packing capital of the world.

Armour earned his first capital in California mining endeavours and cofounded a grain-dealing and meatpacking business in Milwaukee, Wis., in 1863. Anticipating a sharp decline in pork prices near the end of the American Civil War (1861–65), he made nearly \$2 million buying pork at depressed rates and selling it for far more in New York City. He became involved in his brother Herman Ossian Armour's grain-commission house in Milwaukee, to which he added a pork-packing plant in 1868. During the following decade the family's interests were concentrated in Chicago, and Philip Armour assumed leadership of the firm

Philip Danforth Armour, portrait by an unknown artist, 1914

in 1875. He originated a number of slaughtering techniques, the use of waste products, and the sale of canned meat. When refrigeration was introduced in the 1880s, he established distributing plants in Eastern cities and began exporting meat products to Europe.

In his later years Armour employed part of his wealth, estimated at \$50 million, for philanthropic purposes, founding the Armour Mission and the Armour Institute of Technology (1892, later the Illinois Institute of Technology), both in Chicago. After his death, Armour's firm continued to prosper under his son, Jonathan Ogden Armour, at whose retirement in 1923 the company was the largest meatpacking firm in the world.

armoured vehicle, armoured also spelled ARMORED, motor vehicle that is fitted with partial or complete armour plating for protection against bullets, shells, or other projectiles. Armoured vehicles for military use can move either on wheels or on two endless metal chains called tracks. The tank (*q.v.*) is the principal fighting armoured vehicle. Other military types include armoured personnel carriers, armoured cars, self-propelled guns, tank destroyers, and mobile anti-aircraft systems. The classification also includes armoured cars used for such civilian purposes as transporting valuables.

Armoured personnel carriers are the most widely used armoured vehicles after tanks. They are tracked, armoured vehicles that are used for transporting infantrymen into battle or as combat platforms from which infantry can fight without dismounting. Armoured personnel carriers first appeared in large numbers early in World War II, when the Germans adopted them to carry the infantry contingents of their panzer divisions into battle. These vehicles, though only partly armoured half-tracks, began the replacement of unarmoured trucks for this purpose. After World War II many nations developed fully tracked carriers with all-around armour protection and a mounted heavy machine gun. The most modern infantry fighting vehicles are armed with an automatic cannon and antitank guided missiles.

The armoured car is an armoured, wheeled vehicle that is usually fitted with a 20-millimetre to 90-millimetre gun and a machine gun. Armoured cars made their first appearance in large numbers in World War II, particularly in the North African theatre. Armoured cars perform poorly on wet or uneven terrain in comparison to tracked vehicles, but the former move faster on roads or other flat expanses. They are lightly armoured and rely on speed for their protection, thus making them good reconnaissance vehicles.

The self-propelled gun is essentially a 100-millimetre to 200-millimetre artillery piece mounted in a turret on a medium or light tracked or wheeled vehicle that is armoured to varying degrees. It is a useful antitank weapon, though a highly vulnerable one. A related type of vehicle is a tank destroyer, a tracked vehicle that relies on speed and firepower and has only a minimum of armour protection. Tank destroyers are usually armed with either an antitank guided-missile launcher, an 80-millimetre to 90-millimetre gun, or a recoilless rifle. Anti-aircraft guns can be made mobile by mounting them on a tracked or wheeled vehicle. The armament often consists of automatic cannons or surface-to-air missile launchers.

Armoured cars for civilian use made their appearance shortly after World War I. Armour was applied to truck bodies to enable the safe transport of currency, payrolls, and other valuables without fear of easy loss to armed robbers. These vehicles are essentially bulletproof

chambers with armoured doors and gun ports and with space inside for valuables and armed guards.

Armoury Museum, Russian ОРУЖЕЙНАЯ ПАЛАТА, in Moscow, oldest museum in Russia. It is housed in a building between the Great Kremlin Palace and the Kremlin wall, was designed by Konstantin A. Thon, and was built between 1844 and 1851. The museum was originally founded to house the treasures accumulated over the centuries by Russia and is Russo-Byzantine in style. The treasures of the Kremlin cathedrals and the Synodal Treasury were added after the Revolution.

Arms and armour include the armour of Boris Godunov and the jewel-encrusted helmet of Tsar Michael. Among the examples of enamel work, icons, and jewelry are some famous works of the Russian goldsmith Peter Fabergé. There are also vestments and fabrics and European gold and silver, including one of the finest collections of 16th- and 17th-century English silver in the world and French porcelain from the Sèvres factory. The thrones include one of inlaid ivory that belonged to Ivan the Terrible and a gold throne presented to Boris Godunov in 1604 by the shah of Persia. The Russian state regalia, including crowns and other precious objects, is housed in the museum.

arms, coat of, the principal part of a system of hereditary symbols dating to early medieval Europe, used primarily to establish identity in battle. Arms evolved to denote family descent, adoption, alliance, property ownership, and, eventually, profession. Today they may be granted to organizations such as schools, universities, guilds, learned societies, churches, fraternities, and even corporations, as well as to individuals.

The origin of the term *coat of arms* is in the surcoat, the cloth tunic worn over armour to shield it from the sun's rays. It repeated the bearer's arms as they appeared on his shield and banner or pennon. More properly termed an armorial or heraldic achievement, it consists of a shield, helmet, the mantling that protects his neck from the sun, the wreath that secures the mantling and crest to the helmet, and the crest itself, *i.e.*, the device above the helmet. Additions to the achievement may include badges, mottoes, supporters, a crown or coronet, and a compartment (base).

The surface of the shield, or escutcheon, is divided from the point of view of the bearer of the shield into chief and base (top and bottom), sinister and dexter (left and right). Combinations of these terms, together with pale (the centre vertical third) and fess (the centre horizontal third) create a grid of nine points on which to locate the charges, or designs, placed upon the shield. The tinctures (colours) of the shield and its charges are termed metals (or: gold, yellow; argent: silver, white) and colours (sable: black; gules: red; azure: blue; vert: green; and purpure: purple). They may also mimic natural or artificial furs (ermine, ermine, ermonois, vair, and pean). Ordinaries are charges consisting of simple shapes such as crosses, chevrons, or bends (diagonal bars) that may be of any tincture and may be combined in great variety.

Colleges of arms are responsible for the maintenance, regulation, and granting of coats of arms. In England the College of Arms was established in London in 1484 and is under the control of the Earl Marshal. *See also* heraldry.

arms, roll of, book describing (blazoning) and illustrating the arms of persons present at a particular battle or tournament. Not only of historical interest, they are excellent examples of heraldic art as well. There has been no break in the compilation of rolls of arms for official purposes since their origin in mid-13th-century England. The official registers of heraldic administrations (such as the Lyon

Court in Scotland) still maintain collections of rolls of arms recording armorial ensigns and insignia of historical import.

arms control, any international limitation of the development, testing, production, deployment, or use of weapons that, at the same time, accepts the inevitability of the continued existence of national military establishments. Implied in arms control is some form of collaboration between generally antagonistic states in areas of military policy.

In a broader sense, "arms control" embraces the related notion of disarmament (*q.v.*). Complete disarmament is the elimination of a nation's entire military capacity. Partial disarmament, by contrast, can consist of the elimination of certain types or classes of weapons or a general reduction (but not elimination) of all classes of weapons. Disarmament agreements usually directly prohibit the possession or production of weapons, while arms-control agreements act more indirectly by setting limitations on the testing, deployment, or use of weapons. Arms-control agreements proved particularly useful in limiting the nuclear arms race in the second half of the 20th century, and by century's end the term "arms control" had come to denote any disarmament or arms-limitation agreement.

The possibility of arms control did not come before an international assembly until 1899, at the first Hague Convention (*q.v.*). Although this and later conventions failed to limit armaments, they did adopt a number of agreements on related matters. After World War I, the Washington Conference (*q.v.*) of 1921–22 incorporated disarmament, arms-limitation, and arms-control agreements in order to halt the Great Powers' naval arms race.

There were no further major arms-control agreements until the 1960s, by which time the world's two emergent superpowers, the United States and the Soviet Union, had each developed large arsenals of nuclear weapons. The possibility of both nations' mutual destruction in an intercontinental exchange of nuclear-armed missiles prompted them to undertake increasingly serious efforts to limit first the testing, then the deployment, and finally the possession of these weapons.

The United States and the Soviet Union thus took the lead in arms control through the sponsorship of several international agreements of a limited risk character. The first such agreement was the Nuclear Test-Ban Treaty (*q.v.*; 1963), which banned tests of nuclear weapons in the atmosphere, in outer space, and underwater, thus effectively confining nuclear explosions to underground sites. In 1968 the two superpowers took the lead in a treaty whereby they agreed not to promote the spread, or proliferation, of nuclear weapons to countries that did not already possess them. (*See* Non-proliferation of Nuclear Weapons, Treaty on the.)

The most substantial advances in limiting the superpowers' nuclear arms race in the 1970s came out of the Strategic Arms Limitation Talks (*q.v.*), or SALT, which were intended to restrain the two nations' continuing buildup in nuclear-armed intercontinental (long-range or strategic) ballistic missiles (ICBMs). One major part of the SALT I complex of agreements reached in 1972 severely limited each nation's future deployment of antiballistic missiles (ABMs), which could be used to destroy incoming ICBMs; the agreement thus kept both sides subject to the deterrent effect of the other's strategic offensive forces. Another portion of the SALT I agreement froze the number of each side's ICBMs and submarine-launched ballistic missiles (SLBMs) at current levels. The SALT II agreement of 1979 set limits on each side's store of multiple independent reentry vehicles (MIRVs), which are strategic missiles equipped with multiple nuclear warheads capable of hitting different tar-

gets on the ground. This agreement placed limits on the number of MIRVed ICBMs, SLBMs, strategic bomber planes, and other strategic launchers each side possessed. The SALT agreements stabilized the strategic arms race between the two superpowers, but at very high force levels, with each nation possessing many times the long-range offensive capacity needed to utterly destroy the other in a nuclear war.

The accession of a liberalizing Soviet regime under Mikhail Gorbachev in 1985 intensified arms-control efforts between the two superpowers and bore its first fruits in the Intermediate-Range Nuclear Forces Treaty (*q.v.*) of 1987, in which the United States and the Soviet Union agreed to eliminate their stocks of intermediate- and medium-range land-based missiles. In the meantime, a new set of bilateral negotiations between the superpowers had begun in 1982 with the aim of reducing rather than merely limiting their arsenals of nuclear warheads and launch platforms (missiles and bombers). These negotiations were called the Strategic Arms Reduction Talks (*q.v.*), or START. In the START I treaty signed in 1991, both superpowers agreed to reduce their strategic nuclear forces by 25 to 30 percent. Both sides also began eliminating various types of tactical (battlefield) nuclear-armed weapons, including artillery shells, depth charges, land mines, bombs, and the warheads carried on various tactical missiles.

Following the breakup of the Soviet Union in late 1991, newly sovereign Russia undertook efforts to drastically reduce its nuclear and conventional armed forces through unilateral actions and agreements with the United States. Newly independent Ukraine, Belarus, and Kazakhstan, the other inheritors of the Soviet Union's nuclear arsenal, pursued policies aimed at eventually attaining complete nuclear disarmament. In 1992 an informal agreement (START II) was reached between the United States and Russia that would further drastically reduce each nation's strategic nuclear forces over a period extending into the early 21st century. The Treaty on the Non-proliferation of Nuclear Weapons was extended indefinitely by a vote of 174 countries at the United Nations in 1995, yet the detonation of nuclear devices by India and Pakistan in 1998 ushered in a new era of concern over the spread and potential use of such weapons. Citing these concerns, the United States withdrew from its agreements limiting the development and deployment of ABMs in 2002.

Following the collapse of the Soviet Union there was an increase in the availability of all types of weapons, which fueled regional disputes and prompted increased fears among arms control specialists of the proliferation of other classes of weapons, including antipersonnel land mines, small arms, and, particularly, chemical and biological weapons. By 2000 more than 150 countries had signed the Biological Weapons Convention (1972), banning the production, storage, and use of biological weapons, and in 1997 the Chemical Weapons Convention (CWC) came into force. The CWC called for the complete destruction of all stockpiles of chemical weapons throughout the world by 2007. (See also International Campaign to Ban Landmines.)

Armstrong, Edwin H., in full EDWIN HOWARD ARMSTRONG (b. Dec. 18, 1890, New York, N.Y., U.S.—d. Jan. 31/Feb. 1, 1954, New York City), American inventor who laid the foundation for much of modern radio and electronic circuitry, including the regenerative and superheterodyne circuits and the frequency modulation (FM) system.

Early life. Armstrong was from a genteel, devoutly Presbyterian family of Manhattan. Armstrong was a shy boy interested from childhood in engines, railway trains, and all mechanical contraptions.

At age 14, fired by reading of the exploits of Guglielmo Marconi in sending the first wireless message across the Atlantic Ocean, Armstrong decided to become an inventor. He built a maze of wireless apparatus in his family's attic and began the solitary, secretive work that absorbed his life. Except for a passion for tennis and, later, for fast motor cars, he developed no other significant interests. Wireless was then in the stage of crude spark-gap transmitters and iron-filing receivers, producing faint Morse-code signals, barely audible through tight earphones. Armstrong joined in the hunt for improved instruments. On graduating from high school, he commuted to Columbia University's School of Engineering.

In his junior year at Columbia, Armstrong made his first, most seminal invention. Among the devices investigated for better wireless reception was the then little understood, largely unused Audion, or three-element vacuum tube, invented in 1906 by Lee De Forest, a pioneer in the development of wireless telegraphy and television. Armstrong made exhaustive measurements to find out how the tube worked and devised a circuit, called the regenerative, or feedback, circuit, that suddenly, in the autumn of 1912, brought in signals with a thousandfold amplification, loud enough to be heard across a room. At its highest amplification, he also discovered, the tube's circuit shifted from being a receiver to being an oscillator, or primary generator, of wireless waves. As a radiowave generator, this circuit is still at the heart of all radio-television broadcasting.

Armstrong's priority was later challenged by De Forest in a monumental series of corporate patent suits, extending more than 14 years, argued twice before the U.S. Supreme Court, and finally ending—in a judicial misunderstanding of the nature of the invention—in favour of De Forest. But the scientific community never accepted this verdict. The Institute of Radio Engineers refused to revoke an earlier gold-medal award to Armstrong for the discovery of the feedback circuit. Later he received the Franklin Medal, highest of the United States' scientific honours, reaffirming his invention of the regenerative circuit.

This youthful invention that opened the age of electronics had profound effects on Armstrong's life. It led him, after a stint as an instructor at Columbia University, into the U.S. Army Signal Corps laboratories in World War I in Paris, where he invented the superheterodyne circuit, a highly selective means of receiving, converting, and greatly amplifying very weak, high-frequency electromagnetic waves, which today underlies 98 percent of all radio, radar, and television reception over the airways. It brought him into early association with the man destined to lead the postwar Radio Corporation of America (RCA), David Sarnoff, whose young secretary Armstrong later married. Armstrong himself returned after the war to Columbia University to become assistant to Michael Pupin, the notable physicist and inventor and his revered teacher. In this period he sold patent rights on his circuits to the major corporations, including RCA, for large sums in cash and stock. Suddenly, in the radio boom of the 1920s, he found himself a millionaire. But he continued to teach at Columbia, financing his own research, working along with Pupin, whose professorship he inherited, on the long-unsolved problem of eliminating static from radio.

Invention of FM broadcasting. In 1933 Armstrong secured four patents on advanced circuits that were to solve this last basic problem. They revealed an entirely new radio system, from transmitter to receiver. Instead of varying the amplitude, or power, of radio waves to carry voice or music, as in all radio before then, the new system varied, or modulated, the waves' frequency (number of waves per second) over a wide band of frequencies. This created a carrier wave that natural stat-

ic—an amplitude phenomenon created by electrical storms—could not break into. As a result, FM's wide frequency range made possible the first clear, practical method of high-fidelity broadcasting.

Because the new system required a basic change in transmitters and receivers, it was not embraced with any alacrity by the established radio industry. Armstrong had to build the first full-scale FM station himself in 1939 at a cost of more than \$300,000 to prove its worth. He then had to develop and promote the system, sustain it through World War II (while he again turned to military research), and fight off postwar regulatory attempts to hobble FM's growth. When FM slowly established itself, Armstrong again found himself entrapped in another interminable patent suit to retain his invention. Ill and aging in 1954, with most of his wealth gone in the battle for FM, he took his own life.

The years have brought increasing recognition of Armstrong's place in science and invention. FM is now the preferred system in radio, the required sound channel in all television, and the dominant medium in mobile radio, microwave relay, and space-satellite communications. Posthumously, Armstrong was elected to the pantheon of electrical greats by the International Telecommunications Union, to join such figures as André-Marie Ampère, Alexander Graham Bell, Michael Faraday, and Guglielmo Marconi. (L.P.L.)

Armstrong, Henry, original name HENRY JACKSON (b. Dec. 12, 1912, Columbus, Miss., U.S.—d. Oct. 24, 1988, Los Angeles, Calif.), American boxer, the only professional boxer to hold three world championship titles simultaneously.

Armstrong fought as an amateur from 1929 to 1932. Early in his career he boxed under the name of Melody Jackson. He first won the featherweight (126-pound) title by knocking out Petey Sarron in six rounds on Oct. 29, 1937. On May 31, 1938, he took the welterweight (147-pound) championship from Barney Ross by decision, and on August 17 of that year he defeated Lou Ambers by decision to win the lightweight (135-pound) title. Late in 1938 he resigned the featherweight championship without having defended it, and on Aug. 22, 1939, he lost the lightweight crown in a 15-round return fight with Ambers.

Armstrong was a busy welterweight champion, successfully defending the title 19 times in somewhat more than two years. On Oct. 4, 1940, he lost the championship when Fritzie Zivic outpointed him in 15 rounds. His attempt to regain the championship from Zivic on Jan. 17, 1941, resulted in his knockout in the 12th round by Zivic. On March 1, 1940, Armstrong attempted to win from Ceferino Garcia the New York State version of the middleweight (160-pound) title, which was then in dispute, but the decision was a draw, permitting Garcia to retain the championship.

Armstrong retired from the ring in 1945. He had fought 26 world title fights and from 1931 to 1945 had fought 175 bouts, winning 97 by knockouts. Intelligent and a fluent speaker, he turned to preaching and was ordained a Baptist minister in 1951.

Armstrong, Henry Edward (b. May 6, 1848, Lewisham, Kent [now a part of London], Eng.—d. July 13, 1937, Lewisham), English organic chemist whose research in substitution reactions of naphthalene was a major service to the synthetic-dye industry.

Armstrong studied at the Royal College of Chemistry, where he developed a method of determining organic impurities (sewage) in drinking water, which was used in the sanitary surveys of water supplies and helped to control typhoid fever. In 1867, he went to study under

Hermann Kolbe at the University of Leipzig in Germany and secured a Ph.D. there in 1870. In 1871 he became professor of chemistry at the London institution Finsbury Circus (later Finsbury Technical College) and in 1879 was appointed to help organize the teaching of chemistry and physics at the City and Guilds of London Institute. From 1884 he taught at the Central Technical College, retiring in 1911. He had been elected a fellow of the Royal Society in 1876.

Armstrong's classic researches dealt in part with substitution in the hydrocarbon naphthalene, a problem on which he published some 60 treatises, which, with the work of his collaborators, securely established the chemistry of a substance and its derivatives that were of the greatest technical importance in the dyestuffs industry. He also pioneered in organic crystallography, contributed much to the understanding of the chemical composition of camphor and related terpene compounds, and devised a centric formula for benzene.

Armstrong, John (b. Nov. 25, 1758, Carlisle, Pa. [U.S.]—d. April 1, 1843, Red Hook, N.Y.), American soldier, diplomat, and politician who, as U.S. secretary of war during the War of 1812, was blamed for the British capture of Washington, D.C.

Armstrong fought in the U.S. War of Independence (1775–83) and, as an officer in the Continental Army, was apparently the author of the Newburgh Addresses attacking Congress. After the war, he entered politics in New York, serving briefly as U.S. senator, and was U.S. minister to France (1804–10). When the War of 1812 began, Armstrong served as a brigadier general and, from February 1813 until September 1814, as secretary of war under President James Madison, with whom he shared blame for the failure to protect Washington, D.C., from British troops, who burned the Capitol on Aug. 24, 1814. Unpopularity forced Armstrong to resign his cabinet position.

Armstrong, Lance (b. Sept. 18, 1971, Plano, Texas, U.S.), American cyclist, who became the first rider to win seven Tour de France titles (1999–2005).

Armstrong embarked on an amateur cycling career while still in high school. He turned professional in 1992 and rode the Tour de France from 1993 to 1996. After the 1996 Tour, Armstrong fell ill, and in October his physicians diagnosed testicular cancer, which had by that time also spread to his lungs and brain. Months of treatments followed before he could attempt his comeback in a sport so demanding that some doctors questioned whether Armstrong's body could bear the strain of a three-week race. In 1998 he won his first important race since his cancer was diagnosed, the Tour de Luxembourg.

On July 25, 1999, Armstrong became the second American ever to win the Tour de France, the sport's most prestigious race, and the first to win for an American team (three-time winner Greg LeMond had raced with European teams). Riding with the U.S. Postal Service team, Armstrong won the race by 7 minutes and 37 seconds. In 2000 Armstrong won his second Tour 6 minutes and 2 seconds ahead of his nearest competitor. His physical strength in the mountain climbs proved critical to his wins in 2001 and 2002. He won the 2003 race by 61 seconds to claim his fifth consecutive Tour de France, tying a record set by Miguel Indurain. In 2004 Armstrong won his record-setting sixth consecutive race. After winning his seventh Tour in 2005, Armstrong announced his retirement. (S.Ab./Ed.)

Armstrong, Louis (Daniel), byname SATCHMO (diminutive of "Satchel Mouth") (b.

Aug. 4, 1901, New Orleans, La., U.S.—d. July 6, 1971, Corona, Queens, N.Y.), the leading trumpeter in jazz history.

A prolifically gifted musician, Armstrong as a child followed the brass bands around New Orleans and came to know many of the pioneers of jazz. He played the trumpet in

Louis Armstrong
AP/Wide World Photos

marching bands and on the Mississippi riverboats, but he did not really come into his own until, in 1922, his hero, King Oliver, then leading a band in Chicago, sent for him to play second trumpet. A series of recordings with Oliver's Creole Jazz Band resulted, with such pieces as "Dippermouth Blues," "Canal Street Blues," and other blues.

Until his advent, jazz had been based on a three-instrument front line of clarinet-trumpet-trombone, in which individual gifts were subordinated to the demands of the ensemble. It was evident, however, that as soon as individual virtuosity reached a certain peak and a player evolved the ability to create solos more profound than anything the ensemble could offer, then this New Orleans convention was doomed. Armstrong, with his creativity, ended the convention. The series of recordings that he made between 1925 and 1928 with his Hot Five and Hot Seven ensembles established the preeminence of the virtuoso soloist. With these groups, Armstrong made records that included "Savoy Blues," "Potato Head Blues," and "West End Blues."

Harmonically, Armstrong was always one of the clearest thinkers, and, despite the complex evolution of jazz after his youth, he remained rooted in the style that first established his reputation. With his beauty of tone, instrumental range, and gift for melodic variations, his extroverted style enabled him to bring jazz to audiences who cared little for the music. One of his most important contributions was to popularize a rhythmic approach in improvising that became known as jazz swing feeling. Another outcome of his burgeoning career was his invention of the "scat" vocal, in which the voice, by abandoning words in favour of conventional but meaningless syllables, reproduces the nuances of instrumental improvisation. Armstrong made many vocal records, and the scat vocal was imitated by jazz singers, including Ella Fitzgerald and Al Jarreau.

As a composer, Armstrong is associated with such early jazz hits as "Dippermouth Blues" (with King Oliver), "Wild Man Blues" (with Jelly Roll Morton), and "Gut Bucket Blues." Armstrong also performed in a number of films, from *Diamond Lil* with Mae West to *Hello Dolly!* with Barbra Streisand. Armstrong autobiographies include *Swing That Music* (1936) and *Satchmo: My Life in New Orleans* (1954). His home in Corona, Queens, N.Y., is a national historic landmark and museum.

BIBLIOGRAPHY. Biographies include Max Jones and John Chilton, *Louis: The Louis Armstrong Story, 1900–1971* (1971, reprinted 1988); James Lincoln Collier, *Louis Armstrong, an American Genius* (1983); Laurence Bergreen, *Louis Armstrong: An Extravagant Life* (1997); and Gary Giddins, *Satchmo: The Genius of Louis Armstrong* (2001).

Armstrong, Neil (Alden) (b. Aug. 5, 1930, Wapakoneta, Ohio, U.S.), American astronaut, the first man to set foot on the Moon.

Armstrong became a licensed pilot on his 16th birthday and a naval air cadet in 1947. His studies in aeronautical engineering at Purdue University, West Lafayette, Ind., were interrupted in 1950 by the Korean War, in which as a naval aviator he was shot down once and was awarded three Air Medals. In 1955 he became a civilian research pilot for the National Advisory Committee for Aeronautics (NACA), later the National Aeronautics and Space Administration (NASA). He flew more than 1,100 hours, testing various supersonic fighters as well as the X-15 rocket plane.

In 1962 he joined the space program with the second group of astronauts. On March 16, 1966, Armstrong, as command pilot of Gemini 8, and David R. Scott rendezvoused with an unmanned Agena rocket and completed the first manual space-docking maneuver. After the docking, a rocket-thruster malfunction forced them to separate from the Agena. Armstrong then regained control of the Gemini craft and made an emergency splashdown in the Pacific Ocean.

On July 16, 1969, Armstrong, along with Edwin E. Aldrin, Jr., and Michael Collins, blasted off in the Apollo 11 vehicle. Four days later, at 4:18 PM, U.S. Eastern Daylight Time (EDT), the Eagle lunar landing module, guided manually by Armstrong, touched down on a plain near the southwestern edge of the Sea of Tranquillity (Mare Tranquillitatis). At 10:56 PM EDT, July 20, 1969, Armstrong stepped from the Eagle onto the Moon's dusty surface with the words, "That's one small step for [a] man, one giant leap for mankind." (Armstrong forgot to say "a" in the

Neil Armstrong, 1969
AP/Wide World

excitement of the moment.) Armstrong and Aldrin left the module for more than two hours and deployed scientific instruments, collected surface samples, and took numerous photographs.

On July 21, after 21 hours and 36 minutes on the Moon, they lifted off to rendezvous with Collins and begin the voyage back to Earth. After splashdown in the Pacific at 12:51 PM EDT on July 24, the three astronauts spent 18 days in quarantine to guard against possible contamination by lunar microbes. During the days that followed and during a tour of 21 nations, they were hailed for their part in the opening of a new era in the exploration of the universe.

Armstrong resigned from NASA in 1971. From 1971 to 1979 he was professor of aerospace engineering at the University of Cincinnati (Ohio). After 1979 Armstrong served as chairman or director for a number of companies. He also sat on the National Commission on Space (NCOS), a panel charged with setting goals for the space program, and on the National Commission on the Space Shuttle Challenger Accident, the group appointed in 1986 to analyze the safety failures in the Challenger disaster.

Armstrong, Samuel Chapman (b. Jan. 30, 1839, Maui, Hawaii—d. May 11, 1893, Hampton, Va., U.S.), Union military commander of black troops during the American Civil War and founder of Hampton Institute, a vocational educational school for blacks.

The son of American missionaries to Hawaii, Armstrong attended Oahu College for two years before going to the United States in 1860. He enrolled at Williams College, but on the outbreak of the Civil War, he accepted a commission as captain in the 125th New York Regiment. He recruited and trained his own troops and led them in several battles, including Gettysburg.

Armstrong was put in command of the 9th Regiment, consisting entirely of black troops. By the end of the war, he held the rank of brigadier general, and his troops had distinguished themselves on many occasions.

After the war, Armstrong became an agent of the Freedmen's Bureau and, in 1866, took charge of a huge camp of former slaves in Hampton, Va. Recognizing the need for those blacks to receive an education, Armstrong in 1867 convinced the American Missionary Association and a private benefactor to purchase land in Hampton and establish a vocational training institution there. Hampton Normal and Industrial Institute opened in 1868. For the next 25 years, Armstrong laboured to a leading centre for both vocational training and academic education for Southern blacks.

Armstrong (of Craggside), William George Armstrong, Baron, also called (1859–87) SIR WILLIAM GEORGE ARMSTRONG (b. Nov. 26, 1810, Newcastle upon Tyne, Northumberland, Eng.—d. Dec. 27, 1900, Craggside, Northumberland), British industrialist and en-

William George Armstrong, c. 1870
BBC Hulton Picture Library

gineer who invented high-pressure hydraulic machinery and revolutionized the design and manufacture of guns.

Armstrong abandoned his Newcastle law practice in 1847 to devote full time to scientific experimentation. He founded an engineering works at Elswick-on-Tyne to build hydraulic cranes. Because his hydraulic machinery was dependent for power on water mains or reservoirs, he invented, in 1850, a hydraulic accumulator. It comprised a large water-filled cylinder with a piston that could raise water pressure within the cylinder and in supply pipes to 600 pounds per square inch (42 kg per square cm). Thus machinery such as hoists, capstans, turntables, and dock gates could be worked in almost any situation.

He next improved ordnance for the British army. He shrank metal rings onto an inner steel barrel, later coiling a strip of wrought iron into a long helix and welding it to the barrel. This process, used by others, was most successfully developed by Armstrong. He also emphasized breechloading, rifled bores, and elongated projectiles. Armstrong was elected a fellow of the Royal Society in 1843 and created a baron in 1887.

army, a large organized force armed and trained for war, especially on land. The term may be applied to a large unit organized for independent action, or it may be applied to a nation's or ruler's complete military organization for land warfare.

Armies and warfare are treated in a number of articles in the MACROPAEDIA. For general considerations of armies and warfare, see War, Theory and Conduct of; War, Technology of. For the history of major modern conflicts, see World Wars; International Relations; European History and Culture. See also the INDEX for individual wars, battles, and other military subjects and for individual countries and their histories.

Arnauld FAMILY, French family of the lesser nobility that came to Paris from Auvergne in the 16th century and is chiefly remembered for its close connection with Jansenism (a Roman Catholic movement that propounded heretical doctrines on the nature of free will and predestination) and with the Jansenist religious communities of Port-Royal de Paris and Port-Royal des Champs.

The founder of the family, Antoine Arnauld (1560–1619), was born in Paris, the son of Antoine Arnauld, seigneur de la Mothe. An eloquent lawyer, he pleaded for the University of Paris against the Jesuits in 1594 and presented his case so forcefully that his speech on this occasion has been called "the original sin of the Arnaulds," as if it were the first cause of the Jesuits' animosity against the family. He married Catherine Marion de Druy, and they had 20 children, 10 of whom died young. All except one of the surviving children were in some way connected with Port-Royal. In 1629 Arnauld's widow became a nun at Port-Royal de Paris, where she died in 1641.

Perhaps the most notable of Arnauld's 10 surviving children were the youngest son, Antoine Arnauld (*q.v.*), who was the leading French Jansenist theologian of the 17th century; daughter Jacqueline-Marie-Angélique Arnauld (*q.v.*), called Mère Angélique, who, as abbess, transferred the community from Port-Royal des Champs (near Versailles) to Paris and made it a centre of Jansenism; and her younger sister, Jeanne-Catherine-Agnès Arnauld (*q.v.*), called Mère Agnès, who twice served as abbess of Port-Royal.

Robert Arnauld d'Andilly (1588–1674), the eldest surviving son, pursued a career in government service. In 1620 he made the acquaintance of the abbot of Saint-Cyran (see Duvergier de Hauranne, Jean), a founder of the Jansenist movement, and under Saint-Cyran's influence he eventually sought to retire from secular life. In about 1644 Arnauld d'Andilly at Port-Royal des Champs entered the ascetic religious community established by several of his nephews, chiefly Antoine Le Maistre. Because of his connection with the French court, Arnauld d'Andilly was especially important in Jansenist political affairs. He was also a poet, a translator of religious texts, and the editor of Saint-Cyran's *Lettres chrétiennes et spirituelles* (1645; "Spiritual and Christian Letters"). His *Mémoires* was published in 1734. Five of Robert Arnauld d'Andilly's daughters became nuns at Port-Royal des Champs.

Robert's younger brother, Henri Arnauld (1597–1692), left his diplomatic career for a life in the church. Ordained a priest, he ultimately became bishop of Angers. He played an important part in the religious controversy, his sympathy lying with the Jansenists. In addition to Mère Angélique and Mère Agnès, four more daughters of Antoine Arnauld eventually became nuns at Port-Royal. The most notable was Catherine Arnauld (1590–1651). She married Isaac Le Maistre, a king's counselor, but, after his death, she too took religious vows and entered Port-Royal.

Antoine Le Maistre (1608–58), Catherine's

eldest son, abandoned worldly society and placed himself under the spiritual direction of Saint-Cyran. Thus guided, Le Maistre and several others—including two of his brothers—established the *solitaires* ("hermits"), a Jansenist ascetic group, at Port-Royal des Champs in about 1638. Early in 1656, as the anti-Jansenist campaign was gaining strength in France, Le Maistre went into hiding in Paris, along with his uncle, Antoine Arnauld, and the philosopher Blaise Pascal, who had been living at Port-Royal. Le Maistre collaborated in the composition of Pascal's *Les Provinciales* (1656–57), a series of letters written in defense of Arnauld, who was, at the time, on trial before the faculty of theology in Paris because of his Jansenist views.

Antoine Le Maistre's youngest brother was Isaac-Louis Le Maistre de Sacy (1613–84). Le Maistre de Sacy, also a student and follower of Saint-Cyran, was ordained in 1649. He became confessor to the nuns and *solitaires* of Port-Royal and was held in high esteem by the Jansenists as a spiritual director. He is best remembered as the principal author of the translation of the New Testament known as the *Nouveau Testament de Mons* (1667; "Mons New Testament"). Fragments of his correspondence with Pascal are preserved in the publication *Entretien avec M. de Sacy* ("Conversation with M. de Sacy").

Arnauld, Antoine, byname THE GREAT ARNAULD (b. Feb. 6, 1612—d. Aug. 8, 1694, Brussels, Spanish Netherlands [now in Belgium]), leading 17th-century theologian of Jansenism, a Roman Catholic movement that held heretical doctrines on the nature of free will and predestination.

Arnauld was the youngest of the 10 surviving children of Antoine Arnauld, a Parisian lawyer, and Catherine Marion de Druy (see Arnauld family). He studied theology at the Sorbonne and, in 1641, was ordained into the Roman Catholic priesthood. Under the influence of the abbot of Saint-Cyran—a founder of Jansenism and spiritual adviser to several members of the Arnauld family—he published his treatise *De la fréquente communion* (1643; "On Frequent Communion"), defending controversial Jansenist views on the Eucharist and on penance. With his *Théologie morale des Jésuites* (1643; "Moral Theology of the Jesuits"), Arnauld launched his long polemical campaign against the Jesuits, in which Pierre Nicole, a young theologian from Chartres, was to be his collaborator. In 1655 Arnauld wrote two pamphlets in which he affirmed the substantial orthodoxy of Cornelius Otto Jansen (the Belgian theologian who initiated the movement). These works sparked a dispute that resulted in Arnauld's expulsion from the Sorbonne in 1656. It was this controversy that provoked the French philosopher Blaise Pascal to write his defense of Arnauld in the series of letters known as *Les Provinciales* (1656–57). During the period of the great persecution of the Jansenists (1661–69), Arnauld emerged as a leader of the resistance.

The so-called Peace of Clement IX (1669) brought Arnauld some years of tranquillity, beginning with the gracious reception accorded to him by King Louis XIV, and he next turned to writing against the Calvinists and on subjects disputed between Protestants and Roman Catholics.

In 1679, the persecution of Jansenists was renewed and Arnauld sought refuge first in the Netherlands and then in Belgium. He settled permanently in Brussels in 1682, where he was to remain in voluntary exile until his death. Despite the precarious conditions in which he had to work, the amount of Arnauld's writing during his exile was enormous. He not only resumed his attack on the Jesuit casuists in the last six volumes of his *Morale pratique des*

Jésuites (1689–94; the first two had appeared in 1669 and 1682) but also intervened in the dispute over the rights of the French monarch in the Gallican church. The major written works of Arnauld's later years were generated by his disagreements with the French philosopher and theologian Nicolas Malebranche and with Pierre Nicole, his ally in the earlier anti-Jesuit polemics.

Arnauld, Jacqueline-Marie-Angélique, byname MÈRE ANGÉLIQUE (b. 1591—d. Aug. 6, 1661, Port-Royal, Paris), monastic reformer who was abbess of the important Jansenist centre of Port-Royal de Paris. She was one of six sisters of the prominent Jansenist theologian Antoine Arnauld (the Great Arnauld).

Jacqueline Arnauld entered religious life as a child of 9, becoming abbess of the ancient Cistercian house of Port-Royal des Champs (near Versailles) when she was not yet 12. She had become a nun only by the decision of her parents and had had no vocation for a monastic life, but in 1608 she was converted by a visiting Capuchin friar's sermon. She then undertook to reform her monastery. After an arduous struggle, even against her own family, she succeeded, and Port-Royal became a house of deep spirituality. Mère Angélique was later engaged in the reform of several other convents, especially Maubuisson. From 1618 to 1622 she was under the guidance of St. Francis of Sales. It was she who, in 1625–26, transferred the community of Port-Royal des Champs to Paris. In 1635 she came under the influence of the abbot of Saint-Cyran, one of the founders of Jansenism, a Roman Catholic movement that propounded heretical doctrines on the nature of free will and predestination. The period of persecution of Jansenists in France (1661–69) was in its early stages when, from her deathbed, Mère Angélique wrote to the Queen Mother protesting the constraint that had been inflicted on the Port-Royal community.

Arnauld, Jeanne-Catherine-Agnès, byname MÈRE AGNÈS (b. 1593—d. 1671), abbess of the Jansenist centre of Port-Royal and author of the religious community's *Constitutions* (1665). She was one of six sisters of the prominent Jansenist theologian Antoine Arnauld (the Great Arnauld).

Like her older sister, the abbess Mère Angélique (Jacqueline-Marie-Angélique Arnauld), Jeanne Arnauld entered the cloister at an early age. From 1630 to 1636 she governed the Cistercian monastery of Tard, near Dijon. She then returned to Port-Royal, where she was twice elected abbess (1636; 1658). In August 1664, during the period of persecution of Jansenists in France (1661–69), she was removed to a convent at Chaillot and detained there in an attempt to force from her a statement condemning Jansenism. In 1665, with the other nuns from Port-Royal de Paris who had refused to subscribe to the anti-Jansenist formulary, Mère Agnès was transferred to the community's original house, Port-Royal des Champs, near Versailles. After the so-called Peace of Clement IX (1669), which suspended the persecutions, she lived peacefully and was held in general veneration. Mère Agnès was considered a spiritual writer of some distinction, although few of her works were published.

Arnauld d'Andilly, Robert, brother and follower of the prominent Jansenist theologian Antoine Arnauld. See Arnauld family.

Arnaut DANIEL, Arnaut also spelled ARNAUD (b. Ribérac?; fl. 1180–1200), celebrated Provençal poet, troubadour, and master of the *trobar clus*, a poetic style composed of complex metrics, intricate rhymes, and words chosen more for their sound than for their meaning.

A nobleman by birth, Arnaut was a highly regarded travelling troubadour. He is credited with inventing the sestina, a lyrical form of six six-line stanzas, unrhymed, with an elaborate scheme of word repetition. His skill with language was admired by Petrarch and in the 20th century by Ezra Pound and T.S. Eliot. His greatest influence, however, was on Dante, who imitated him and gave him a prominent place in Purgatory as a model for the vernacular poet. Arnaut's speech in Provençal is the only passage in the *Divine Comedy* not in Italian.

Arnaut DE MAREUIL (b. Mareuil-sur-Belle, Périgord; fl. 1170–1200), Perigordian troubadour who is credited with having introduced into Provençal poetry the amatory epistle (*salut d'amour*) and the short didactic poem (*ensenhamen*).

Little is known of Arnaut's life. His early poems were dedicated to his patroness, Adelaide, the daughter of Raymond V, count of Toulouse, and wife of Roger II, viscount of Béziers. Later Arnaut was at the court of William VIII, count of Montpellier. Most of his extant work is passionate love poetry that combines conventional courtly love imagery (extravagant praise of his lady's beauty, despair at her cruel indifference) with unexpectedly delicate sentiment.

Arnd, Johann: see Arndt, Johann.

Arndt, Ernst Moritz (b. Dec. 26, 1769, Schoritz bei Gartz, Rügen, Swed.—d. Jan. 29, 1860, Bonn), prose writer, poet, and patriot who expressed the national awakening in his country in the Napoleonic era.

Arndt was educated at Stralsund, Greifswald, and Jena and qualified for the Lutheran ministry. At the age of 28 he rejected his clerical career and for 18 months travelled through Europe. On his return to Germany the sight of ruined castles along the banks of the Rhine River moved him to bitterness against the French who had destroyed them. He described the impressions of this journey in *Reisen durch einen Teil Deutschlands, Ungarns, Italiens, und Frankreichs in den Jahren 1798/99*, 6 vol. (1801–03; "A Journey Through Parts of Germany, Hungary, Italy, and France in 1798–99").

In 1800 Arndt settled in Greifswald as assistant lecturer in history and in 1803 published *Germanien und Europa*, in which he proclaimed his views on French aggression. His subsequent *Versuch einer Geschichte der Leibeigenschaft in Pommern und Rügen* (1803) is, as the title suggests, a history of serfdom in Pomerania and Rügen that resulted in its abolition three years later by the Swedish king Gustav IV. In 1806 Arndt was appointed to the chair of history at the University of Greifswald and published the first part of his *Geist der Zeit* (*Spirit of the Times*, 1808), in which he called on his countrymen to shake off the French yoke. To escape the vengeance of Napoleon, he took refuge in Sweden, from where he continued to communicate his patriotic ideals to his countrymen in pamphlets, poems, and songs.

Arndt returned to Germany in 1809. In 1812 he was summoned to St. Petersburg to assist in the organization of the final struggle against France. Meanwhile, he produced further patriotic songs and pamphlets. When, after the peace, the University of Bonn was founded in 1818, Arndt was appointed to the chair of modern history. In this year appeared the fourth part of his *Geist der Zeit*, in which he criticized the reactionary policy of the German powers. The boldness of his demands for reform offended the Prussian government, and in the summer of 1819 he was arrested. He was soon set free but was not allowed to teach. In 1840 he was reinstated and in 1841 was appointed rector of the university. After the revolutionary outbreak of 1848, he took

his seat as one of the deputies to the national assembly at Frankfurt am Main. He took part in the deputation that offered the crown to Frederick William IV, but, indignant at the King's refusal to accept it, he retired from public life.

Not all of Arndt's lyrical poems were inspired by political ideas, nor was he a merely chauvinistic figure. Many of the *Gedichte* (1804–18, complete ed. 1860; "Poems") are religious poems of great beauty.

Other important works are his autobiography, *Erinnerungen aus dem äusseren Leben* (1840; "Recollections from the External Life"), the most valuable source of information for Arndt's life; and *Meine Wanderungen und Wandelungen mit dem Reichsfreiherrn Heinrich Karl vom Stein* (1858; "My Travels and Saunterings with the Baron Heinrich Karl von Stein"). A notable edition of his works is that of H. Meisner and R. Geerds, 16 vol. (1908). Studies include A.G. Pundt's *Arndt and the National Awakening in Germany* (1935) and H. Scurla's *E.M. Arndt*, 2nd ed. (1952).

Where the same name may denote a person, place, or thing, the articles will be found in that order

Arndt, Johann, Arndt also spelled ARND (b. Dec. 27, 1555, Edderitz, Anhalt—d. May 11, 1621, Celle, Hanover), Lutheran theologian whose mystical writings were widely circulated in Europe in the 17th century.

Arndt studied at Helmstadt, Wittenberg, Strasbourg, and Basel. In 1583 he became a pastor at Badeborn, but in 1590 he was deposed for refusing to remove pictures from his church and to discontinue the use of exorcism in Baptism. Both were considered offenses against the Calvinist concept of strict purity and simplicity. Arndt found asylum in Quedlinburg the same year and in 1599 was transferred to St. Martin's Church at Brunswick.

The principal work among his many writings, which were inspired by the mystics St. Bernard, Johann Tauler, and Thomas à Kempis, is *Vier Bücher von wahren Christentum* (1606–10; "Four Books on True Christianity"). Translated into most European languages and widely distributed in Arndt's time, it served as the foundation of many devotional books, both Roman Catholic and Protestant. Its publication aroused strong controversy among Lutherans. It was also a chief influence in the life of Philipp Jakob Spener (1635–1705), who was a founder of Pietism, a movement that stressed simple Christian living. Arndt held that to follow orthodox doctrine was not enough and that the Christian must undergo a moral purification through righteous living and communion with God.

The opposition aroused by his book caused difficulty for Arndt in Brunswick. In 1609 he moved to Eiseleben and in 1611 to Celle, where he remained until his death.

Arne, Thomas (Augustine) (b. March 12, 1710, London—d. March 5, 1778, London), composer, chiefly of dramatic music and song.

According to tradition, Arne was the son of an upholsterer in King Street, Covent Garden. Educated at Eton, he was intended for the law, but by secretly practicing he acquired such mastery of the violin and keyboard instruments that his father withdrew all objections to a musical career. Except for some lessons from Michael Festing, later leader of the Italian Opera orchestra, Arne was self-taught, and it was at the Opera (which he attended in a footman's livery to obtain free admission) that his musical taste was largely formed. He taught both his sister, later famous as the actress Mrs. Cibber, and his young brother to sing, and they appeared in his first stage work, *Rosamond* (1733). This opera, based

Arne, engraving after F. Bartolozzi (c. 1725–1815)

By courtesy of the National Portrait Gallery, London

on Joseph Addison's libretto of 1707, was set "after the Italian manner," and its bravura air "Rise, Glory, Rise" was sung for the next 40 years.

Arne was soon engaged to write musical afterpieces and incidental music for Drury Lane Theatre, and with *Comus* (1738), John Dalton's adaptation of Milton's masque, he became established as the leading English lyric composer. His light, airy, pleasing melodic style was apparent in *Alfred, a Masque* (notable for "Rule, Britannia") and *The Judgment of Paris*, both produced at the Prince of Wales's residence at Cliveden in 1740. Arne's settings of Shakespeare's songs, written for revivals of *As You Like It*, *Twelfth Night*, and *The Merchant of Venice* in 1740–41, provide the culmination of this early style.

In about 1744 Arne was engaged as composer to Drury Lane Theatre and Vauxhall Gardens, and during the next decade published a number of song collections. In 1759 he was made doctor of music at Oxford, and two years later his oratorio *Judith* was produced, followed by the opera *Artaxerxes* (1762), which held the stage until the early 19th century.

In the final decade of his life, Arne set Garrick's ode for the Stratford Shakespeare jubilee of 1769 and composed music for *The Fairy Prince* (1771), Mason's *Elfrida* (1772), and *Caractacus* (1776).

Arne's early melodic style was natural and elegant, owing something to Scots, Irish, and Italian sources. His later music became more Italianate and ornamented, though in his final years there emerged an opera buffa style that anticipates Sullivan. As the composer of such melodies as "Rule, Britannia," "Blow, Blow, Thou Winter Wind," and "Where the Bee Sucks," Arne, like Purcell, added substantially to the English heritage of song.

Arneth, Alfred, Ritter von (knight of) (b. July 10, 1819, Vienna—d. July 30, 1897, Vienna), historian important chiefly for his work in evaluating and publishing sources for Austrian history found in the Vienna state archives.

In 1841 Arneth was appointed by the Austrian statesman Klemens von Metternich to a post at the state archives, of which he became keeper in 1868. In 1879 he became president of the Imperial Academy of the Sciences, and in 1896 he was appointed chairman of the historical commission of the Bavarian Academy of the Sciences in Munich.

His chief publications concerned the 18th century and derived their value from the special facilities available to him. They include lives of Field Marshal Guido von Starhemberg (1853), Prince Eugene of Savoy (1858), and Maria Theresa (1863–79) and numerous collections of correspondence between Maria Theresa and Marie-Antoinette, Maria Theresa and Joseph II, Joseph II and Leopold, and

Joseph II and Catherine of Russia. His early reminiscences, *Aus meinem Leben*, appeared in 1893.

Arneth had launched a political career as a member of the Frankfurt assembly in 1848, after which he served in the Lower Austrian Landtag (Diet) in 1861 and in the Herrenhaus (House of Lords) from 1869. He supported the liberal constitutional party.

Arngrímur Jónsson (Icelandic historian): see Jónsson, Arngrímur.

Arnhem, German ARNHEIM, *gemeente* (municipality) and capital (1794), Gelderland *provincie* (province), eastern Netherlands, on the north bank of the Lower Rhine (Neder Rijn) River. Possibly the site of the Roman settlement of Arenacum, it was first mentioned in 893. Chartered and fortified in 1233 by Otto II, count of Geldern, it joined the Hanseatic League in 1443. As the residence of the dukes of Geldern, it was often attacked by their Burgundian rivals and in 1543 fell to Charles V, who made it the seat of the Council of Gelderland. It came under the United Netherlands in 1585, and the following year Sir Philip Sidney, the English poet, statesman, and soldier, died there after being wounded in the battle of Zutphen. Seized and dismantled by the French in 1672, Arnhem was refortified in the 18th century only to fall again to the French in 1793. Occupied by the Germans during World War II, it was the object of a heroic but unsuccessful attempt by British and Polish airborne troops to secure the Rhine bridges in September 1944. A British war memorial, cemetery, and museum in the suburb of Oosterbeek commemorate the battle.

Arnhem is a tourist centre and an industrial town. Industries include metallurgy, shipbuilding, and the manufacture of textiles, leather goods, electrical equipment, and chemicals.

Notable landmarks include a town hall (c. 1540), the Roman Catholic church of St. Walburgis (1422), the 15th-century Protestant Grote Kerk (St. Eusebius), and the modern provincial government house. The town has a municipal museum, and the aquarium and fish ponds of The Netherlands Society for Improving Moorland are in Sonsbeek Park. The Netherlands Open-Air Museum (1912), Hoge Veluwe National Park, Zuidelijke Veluwezoom National Park, and the Rijksmuseum Kröller-Müller (one of the major art collections in The Netherlands) are nearby. Pop. (1983 est.) *gemeenter*, 128,598; metropolitan area, 290,746.

Arnhem Land, historical region of northeastern Northern Territory, Australia, extending from Van Diemen Gulf southeastward to the Gulf of Carpentaria and Groote Eylandt. Never fully explored, it has a total area of about 37,000 sq mi (95,900 sq km) and includes a largely tropical plateau lying between the Roper and Victoria rivers. The name Arnhem Land is now used primarily for the large Aboriginal reserve in the area. It has been oc-

Aboriginal cave paintings, Arnhem Land, Northern Territory, Australia

By courtesy of the Australian Information Service

cupied by Aborigines since the late Pleistocene, and there are rock carvings at many sites. The northeast coast was visited in 1623 by the Dutch explorer Jan Carstenz, who named the region for his ship, "Arnhem" ("Aernem"). Since World War II bauxite and uranium mining have become important in the area.

Árni Magnússon (Icelandic antiquarian): see Magnússon, Árni.

Arnica, genus of plants of the composite family (Asteraceae), most of whose approximately 50 species occur in northwestern North America. A typical species, *A. angustifolia*, of Arctic Asia and America, has narrow leaves and orange-yellow flower heads 5 to 7 centimetres (2 to 2.5 inches) across.

One of the most important species (*A. montana*) is a perennial herb of northern and central European highlands. It yields an essential oil formerly used in treating bruises and sprains.

Arniches (y Barrera), Carlos (b. Oct. 11, 1866, Alicante, Spain—d. April 16, 1943, Madrid), popular Spanish dramatist of the early 20th century, best known for works in the *género chico* ("lesser genre"): the one-act zarzuela (musical comedy) and the one-act *sainete* (sketch). These plays were based upon direct observation of the customs and speech of the lower class people of Madrid. He wrote some 270 of them and was considered a master of the genre, along with the Álvarez Quintero brothers. He spent the years of the Spanish Civil War (1936–39) in Buenos Aires and Paris.

Arnim, Achim von, byname of KARL JOACHIM FRIEDRICH LUDWIG VON ARNIM (b. Jan. 26, 1781, Berlin—d. Jan. 21, 1831, Wiepersdorf, Brandenburg), folklorist, dramatist, poet, and story writer whose collection of folk poetry was a major contribution to German Romanticism.

Achim von Arnim, oil painting by an unknown artist

Popperfoto

While a student at the University of Heidelberg, Arnim published jointly with Clemens Brentano a remarkable collection of folk poetry, *Des Knaben Wunderhorn* (q.v.; the title derives from the opening poem, which tells of a youth who brings the empress a magic horn). The first volume (published 1805, dated 1806) was dedicated to Goethe, who reviewed it appreciatively, though others criticized it for lacking philosophical accuracy. The collection was completed in 1808.

Arnim's numerous plays, poems, and novels are forgotten, but a few of his short stories—all strangely compounded of realism and fantasy—are notable contributions to German prose fiction. See also Arnim, Bettina von.

Arnim, Bettina von, byname of ELISABETH KATHARINA LUDOVICA MAGDALENA VON ARNIM, *née* BRENTANO (b. April 4, 1785, Frankfurt am Main—d. Jan. 20, 1859, Berlin), one of the outstanding women writers

in modern German literature, memorable not only for her books but also for the personality they reflect. All of her writings, whatever their ostensible themes, are essentially self-portraits.

Gifted women played a prominent role in the German Romantic movement, and Bettina von Arnim was a Romantic par excellence. She was unconventional to the point of eccentricity; wayward, yet a loyal wife (she married Achim von Arnim [q.v.] in 1811) and a devoted mother to her seven children; susceptible and passionate, but jealous of her personal freedom; capable of enthusiastic devotion, yet absorbed in a cult of her own personality, which verged on narcissism. These paradoxes in her nature she projected into her books. Her three best known works purport to be records of her correspondence with Goethe (*Goethes Briefwechsel mit einem Kinde*, 1835; "Correspondence Between Goethe and a Child"),

Bettina von Arnim, engraving after Armgass von Arnim's copy of a miniature by an unknown artist

with Karoline von Günderode (*Die Günderode*, 1840), and with her brother Clemens Brentano (q.v.; *Clemens Brentanos Frühlingskranz*, 1844). The original letters have been rearranged and retouched, the result being a peculiar blend of documentation and fiction, written in a brilliantly vivid, uninhibited style. Her mother, Maximiliane, *née* von La Roche, and Goethe had been friends before and after Maximiliane's marriage; this friendship ended abruptly when it aroused her husband's jealousy, and 35 years later her daughter took her place. Bettina idolized Goethe (who was 57 when she first met him); she had frequently visited Goethe's mother in Frankfurt and recorded the old lady's tales of the poet's childhood. (Goethe later used her notes when he was writing his autobiography, *Dichtung und Wahrheit*.) Bettina pursued Goethe with her attentions until in 1811 a public quarrel between her and Goethe's wife, Christiane, caused Goethe to disavow.

She stated her political views, which were sympathetic to the underprivileged, in two books written for the special benefit of the king of Prussia, Frederick William IV: *Dies Buch gehört dem König* (1843; "This Book Belongs to the King") and *Gespräche mit Dämonen* (1852; "Conversations with Demons"). Bettina was also a gifted sculptor and musician. In the diversity of her talents and interests, she exhibited the universality that has been regarded as the hallmark of the German Romantic spirit.

Arnim, Hans Georg von (b. 1581, Boitzenburg, Brandenburg—d. April 28 [April 18, old style], 1641, Dresden, Saxony), soldier and statesman prominent in German affairs during the Thirty Years' War. He served (1613–17) with the Swedes under Gustaf II Adolf, with the Poles (1621), with Wallenstein's imperial army (1626) as a field marshal, and with the Saxons (1631–35, 1638–41). A strict

Hans von Arnim, detail from an engraving by Martin Bernigeroth after an oil painting by an unknown artist

Archiv für Kunst und Geschichte, West Berlin

Lutheran, Arnim resigned his imperial commission in protest against the Edict of Restitution (1629). Thereafter he worked for the creation of a "third party," under the Elector of Saxony, to hold the balance between the imperial court and the encroachment of Sweden, France, and Spain, and for a plan of general pacification. He left the Saxon Army in 1635 in protest over the Peace of Prague. Arrested by the Swedes (1637), he escaped and was reinstated in the Saxon Army (1638), but he died while preparing to oust the French and Swedes from German soil.

Arnim, Harry (Karl Kurt Eduard), Graf von (count of) (b. Oct. 3, 1824, Moitzelfitz, Pomerania—d. May 19, 1881, Nice, Fr.), Prussian diplomat whose opposition to Bismarck led to his prosecution and gave rise to the *Arnim Paragraphs*, an addition to the German criminal code that made unauthorized disclosures of official documents a criminal offense.

Arnim entered the diplomatic service in 1850 and served in Rome (1853–55), in Lisbon (1862), and as Prussian envoy to the Holy See (1864). At the first Vatican Council of 1869–70, he supported German bishops who opposed the doctrine of papal infallibility.

Arnim became Prussian envoy to France on Aug. 23, 1871, and ambassador on Jan. 9, 1872, arranging the Franco-German War reparations settlement in June. Soon he came into conflict with Bismarck.

In 1874 a Viennese newspaper published correspondence on the Vatican Council, including Arnim's confidential dispatches. The

Harry von Arnim

By courtesy of the Staatsbibliothek, West Berlin

subsequent inquiry revealed that more important documents from Arnim's Paris embassy were missing. Arnim refused to return some of the missing documents and so was suspected of keeping them in order to prove that his own French policy had been wiser than Bis-

marck's. Bismarck thereupon had him temporarily superannuated, then arrested (Oct. 4, 1874). Condemned to three months' imprisonment, Arnim appealed, but his sentence was increased to nine months.

Arnim went into exile and anonymously published *Pro Nihilo* (1875), a pamphlet attributing his disgrace to Bismarck's jealousy. Convicted of treason, of insulting the Emperor, and of libelling Bismarck, Arnim was sentenced in absentia to five years' penal servitude.

Arno, Peter, original name CURTIS ARNOUX PETERS (b. Jan. 8, 1904, New York City—d. Feb. 22, 1968, Port Chester, N.Y., U.S.), cartoonist whose satirical drawings, particularly of New York café society, did much to establish *The New Yorker* magazine's reputation for sophisticated humour.

While at Yale University (1922–24), Arno was particularly interested in music and organized his own band. He also decorated screens and panels for restaurants. After leaving Yale he went to New York City, where he joined the bohemian life of Greenwich Village and continued to do decorative painting. He was about to give up art to join a band when one of his cartoons was accepted by the newly established *New Yorker*. His association with the magazine lasted until his death.

In the late 1920s Arno's cartoons for *The New Yorker*, dealing with the city's aristocracy, became well known, and by 1931 he was the author of four cartoon books. In 1931 he was co-author of *Here Comes the Bride*, a musical satire produced in October of that year. A good-looking, sophisticated man, Arno played an active part in the world he satirized. Lecherous clubmen and sabled dowagers appeared frequently in his cartoons, collections of which include *Man in the Shower* (1944) and *Sizzling Platter* (1949).

Arno River, Italian FIUME ARNO, Latin ARNUS, principal stream of the Toscana (Tuscany) region, in central Italy. Rising on the slopes of Monte Falterona in the Tuscan Apennines, it flows for 150 mi (240 km) to the Ligurian Sea, receiving the Sieve, Pesa, Elsa, and Era rivers. Its drainage basin covers 3,184 sq mi (8,247 sq km). Navigation on the river is negligible. In its upper course the Arno flows generally south through the former lake basin called Casentino, to turn west and north at Arezzo. The fertile valley of its middle course is called the Valdarno.

Below Florence the river enters a gorge at Golfolina and begins its lower course westward past Empoli and Pisa to the sea, where the ancient delta has been reclaimed and the river reaches the sea through a single mouth. The valley of the Arno has been substantially modified by man: in its upper course the Val di Chiana now drains to the Tiber, and in its middle section are flood-control works (some designed by Leonardo da Vinci), though a sudden flood in 1966 inundated Florence.

Arnobius THE ELDER (fl. 4th century, Africa), early Christian convert who defended Christianity by demonstrating to the pagans their own inconsistencies.

Arnobius was born a pagan but had become a Christian by AD 300. He taught rhetoric at Sicca Veneria in Africa during the reign (284–305) of the Roman emperor Diocletian. Because of his former paganism, Arnobius was suspected, notably by the local bishop, and as a pledge of his conviction he composed the seven books *Adversus nationes* (c. 303; "Against the Pagans"). Nothing further is known about his life.

A general defense of Christianity from pagan calumnies (books 1 and 2) is followed by attacks on Neoplatonism, anthropomorphism, and heathen mythology (books 3–5), concluding with worship of images, temples, and ceremonials (books 6 and 7).

Arnold OF BRESCIA, Italian ARNALDO DA BRESCIA (b. c. 1100, Brescia, Rep. of Venice—d. c. June 1155, Civita Castellana or Monterotondo, Papal States), radical religious reformer noted for his outspoken criticism of clerical wealth and corruption and for his strenuous opposition to the temporal power of the popes. He was prior of the monastery at Brescia, where in 1137 he participated in a popular revolt against the government of Bishop Manfred. His proposals for reforming the clergy and for ending the church's temporal powers caused him to be condemned as a schismatic by Pope Innocent II in 1139.

Banished from Italy, Arnold went to France, where he became a supporter of the renowned theologian and philosopher Peter Abelard. Both were condemned as heretics at the Council of Sens, Fr., in 1141, through the influence of St. Bernard of Clairvaux. Though Abelard submitted, Arnold defiantly continued teaching in Paris until, through the insistence of Bernard, he was exiled by King Louis VII the Young of France in 1141. Arnold fled first to Zürich, then to Passau, Ger., where he was protected by Cardinal Guido, through whose mediation he was reconciled with Pope Eugenius III at Viterbo, Papal States, in September 1145.

Two years earlier the *renovatio senatus* ("renewal of the Senate"), seeking independence from ecclesiastical control, had expelled Innocent and the cardinals, revived the ancient senate, and proclaimed Rome a republic. Eugenius sent Arnold to Rome on a penitential pilgrimage. He soon allied himself with the insurgents and resumed his preaching against the Pope and cardinals. He was excommunicated in July 1148. Arnold's agitation for ecclesiastical reform vitalized the revolt against the Pope as temporal ruler, and he soon controlled the Romans. He also worked to consolidate the citizens' newly won independence.

Pope Adrian IV placed Rome under interdict in 1155 and asked the citizens to surrender Arnold. The Senate submitted, the republic collapsed, and the papal government was restored. Arnold, who had fled, was captured by the forces of the Holy Roman emperor Frederick I Barbarossa, then visiting Rome for his imperial coronation. Arnold was tried by an ecclesiastical tribunal, condemned for heresy, and transferred to the Emperor for execution. He was hanged, his body burned, and his ashes cast into the Tiber River.

Arnold's character was austere and his mode of life ascetic. His followers, known as Arnoldists, postulated an incompatibility between spiritual power and material possessions and rejected any temporal powers of the church. They were condemned in 1184 at the Synod of Verona, Rep. of Venice. Arnold's personality has been distorted through modern poets and dramatists and Italian politicians. He was foremost a religious reformer, constrained by circumstances to become a political revolutionary. G.W. Greenaway's *Arnold of Brescia*, with full bibliography, appeared in 1931.

Arnold, Benedict (b. Jan. 14, 1741, Norwich, Conn.—d. June 14, 1801, London), patriot officer who served the cause of the American Revolution until 1779, when he shifted his allegiance to the British; thereafter his name became an epithet for traitor in the U.S.

Upon the outbreak of hostilities at Lexington, Mass. (April 1775), Arnold volunteered for service and participated with Ethan Allen in the successful colonial attack on British-held Ft. Ticonderoga, N.Y., the following month. That autumn he was appointed by Gen. George Washington to command an expedition to capture Quebec. He marched with 700 men by way of the Maine wilderness, a remarkable feat of woodsmanship and endurance, and, reinforced by Gen. Richard Montgomery, attacked the well-fortified city. The combined assault (Dec. 31, 1775) failed, Montgomery

was killed, and Arnold was severely wounded.

Promoted to the rank of brigadier general, Arnold constructed a flotilla on Lake Champlain and inflicted severe losses on a greatly superior enemy fleet near Valcour Island, N.Y. (Oct. 11, 1776). He returned a hero, but his rash courage and impatient energy had aroused the enmity of several other officers. When in February 1777 Congress created five new major generalships, Arnold was passed over in favour of his juniors. Arnold resented this affront, and only Washington's personal persuasion kept him from resigning.

Two months later he repelled a British attack on Danbury, Conn., and was made a major general, but his seniority was not restored and Arnold felt his honour impugned. Again he tried to resign, but in July he accepted a government order to help stem the British advance into upper New York. He won a victory at Ft. Stanwix (now Rome) in August 1777 and commanded advance battalions at the Battle of Saratoga that autumn, fighting brilliantly until seriously wounded. For his services he was restored to his proper relative rank.

Crippled from his wounds, Arnold was placed in command of Philadelphia (June

Benedict Arnold, engraving by H.B. Hall, 1865

By courtesy of the Library of Congress, Washington D.C.

1778), where he socialized with families of Loyalist sympathies and lived extravagantly. To raise money, he violated several state and military regulations, arousing the suspicions and, finally, the denunciations of Pennsylvania's supreme executive council. These charges were then referred to Congress, and Arnold asked for an immediate court-martial to clear himself.

Meanwhile, in April 1779, Arnold married Margaret (Peggy) Shippen, a young woman of Loyalist sympathies. Early in May he made secret overtures to British headquarters, and a year later he informed the British of a proposed American invasion of Canada. He later revealed that he expected to obtain the command of West Point, N.Y., and asked the British for £20,000 for betraying this post. When his British contact, Maj. John André, was captured by the Americans, Arnold escaped on a British ship, leaving André to be hanged as a spy. The sacrifice of André made Arnold odious to Loyalists, and his reputation was further tarnished among his former neighbours when he led a raid on New London, Conn., in September 1781.

At the end of 1781 Arnold went to England, where he remained, inactive, ostracized, and ailing, for the rest of his life.

Arnold, Sir Edwin (b. June 10, 1832, Gravesend, Kent, Eng.—d. March 24, 1904, London), poet and scholar, best known as the author of *The Light of Asia* (1879), an epic poem that tells, in elaborate language, of the life and teachings of the Buddha. *The Light of the World* (1891), on the Christian theme, was less successful. From 1873 Arnold

was chief editor of *The Daily Telegraph* of London. Before joining the *Telegraph*, he had

Sir Edwin Arnold, pencil drawing by A.-P. Cole, 1903; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

been principal of the British government college at Poona (Pune), India. He was knighted in 1888.

Arnold, Harold De Forest (b. Sept. 3, 1883, Woodstock, Conn., U.S.—d. July 10, 1933, Summit, N.J.), physicist whose research led to the development of long-distance telephony and radio communication.

Arnold studied at Ohio Wesleyan University, Delaware, Ohio, and earned a doctorate at the University of Chicago in 1911. While working for the Western Electric Company, he developed and designed the manufacturing methods for reliable high-vacuum triodes (thermionic tubes) used to provide the amplification needed for transcontinental (1914) and intercontinental (1915) radio telephony.

Arnold also contributed to the development of new magnetic alloys (permalloy and permivar) used in sound reproduction and electroacoustics. In 1925 he was appointed the first director of research of the Bell Telephone Laboratories.

Arnold, Henry Harley, byname HAP ARNOLD (b. June 25, 1886, Gladwyne, Pa., U.S.—d. Jan. 15, 1950, Sonoma, Calif.), air strategist, commanding general of the U.S. Army Air Corps in World War II, who long and successfully advocated a separate air force ranking equally with the Army and the Navy.

Arnold graduated from the U.S. Military Academy at West Point, N.Y., (1907), and in 1911 received flying instruction from Orville Wright. He rose in the ranks of the Air Corps; becoming chief in 1938. Despite the isolationism then prevailing in the U.S., he urged increased appropriations for the air establishment and military aid to the Allies. During the war he commanded the U.S. Army Air

Gen. Hap Arnold

By courtesy of the Library of Congress, Washington, D.C.

Corps throughout the world and served as air representative on the U.S. Joint Chiefs of

Staff and the Allied Combined Chiefs of Staff, greatly influencing strategic air bombardment. In December 1944 he was promoted general of the Army (five stars; later general of the Air Force, the first to hold this rank). The National Defense Act of 1947 created the autonomous Air Force for which he had worked.

Arnold, Mary Augusta: see Ward, Mrs. Humphry.

Arnold, Matthew (b. Dec. 24, 1822, Laleham, Middlesex, Eng.—d. April 15, 1888, Liverpool), English Victorian poet and literary and social critic, noted especially for his classical attacks on the contemporary tastes and

Matthew Arnold, detail of an oil painting by G.F. Watts; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

manners of the "Barbarians" (the aristocracy), the "Philistines" (the commercial middle class), and the "Populace." He became the apostle of "culture" in such works as *Culture and Anarchy* (1869).

Life. Matthew was the eldest son of the renowned Thomas Arnold, who was appointed headmaster of Rugby School in 1828. Matthew entered Rugby (1837) and then attended Oxford as a scholar of Balliol College; there he won the Newdigate Prize with his poem *Cromwell* (1843) and was graduated with second-class honours in 1844. For Oxford Arnold retained an impassioned affection. His Oxford was the Oxford of John Henry Newman—of Newman just about to be received into the Roman Catholic Church; and although Arnold's own religious thought, like his father's, was strongly liberal, Oxford and Newman always remained for him joint symbols of spiritual beauty and culture.

In 1847 Arnold became private secretary to Lord Lansdowne, who occupied a high Cabinet post during Lord John Russell's Liberal ministries. And in 1851, in order to secure the income needed for his marriage (June 1851) with Frances Lucy Wightman, he accepted from Lansdowne an appointment as inspector of schools. This was to be his routine occupation until within two years of his death. He engaged in incessant travelling throughout the British provinces and also several times was sent by the government to inquire into the state of education in France, Germany, Holland, and Switzerland. Two of his reports on schools abroad were reprinted as books, and his annual reports on schools at home attracted wide attention, written, as they were, in Arnold's own urbane and civilized prose.

Poetic achievement. The work that gives Arnold his high place in the history of literature and the history of ideas was all accomplished in the time he could spare from his official duties. His first volume of verse was *The Strayed Reveller, and Other Poems*. By A. (1849); this was followed (in 1852) by another under the same initial: *Empedocles on Etna, and Other Poems*. In 1853 appeared the first volume of poems published under

his own name; it consisted partly of poems selected from the earlier volumes and also contained the well-known preface explaining (among other things) why *Empedocles* was excluded from the selection: it was a dramatic poem "in which the suffering finds no vent in action," in which there is "everything to be endured, nothing to be done." This preface foreshadows his later criticism in its insistence upon the classic virtues of unity, impersonality, universality, and architectonic power and upon the value of the classical masterpieces as models for "an age of spiritual discomfort"—an age "wanting in moral grandeur." Other editions followed, and *Merope*, Arnold's classical tragedy, appeared in 1858, and *New Poems* in 1867. After that date, though there were further editions, Arnold wrote little additional verse.

Not much of Arnold's verse will stand the test of his own criteria; far from being classically poised, impersonal, serene, and grand, it is often intimate, personal, full of romantic regret, sentimental pessimism, and nostalgia. As a public and social character and as a prose writer, Arnold was sunny, debonair, and sanguine; but beneath ran the current of his buried life, and of this much of his poetry is the echo:

From the soul's subterranean depth upborne
As from an infinitely distant land,
Come airs, and floating echoes, and convey
A melancholy into all our day.

"I am past thirty," he wrote a friend in 1853, "and three parts iced over." The impulse to write poetry came typically when

A bolt is shot back somewhere in the breast,
And a lost pulse of feeling stirs again.

Though he was "never quite benumb'd by the world's sway," these hours of insight became more and more rare, and the stirrings of buried feeling were associated with moods of regret for lost youth, regret for the freshness of the early world, moods of self-pity, moods of longing for

The hills where his life rose
And the sea where it goes.

Yet, though much of Arnold's most characteristic verse is in this vein of soliloquy or intimate confession, he can sometimes rise, as in "Sohrab and Rustum," to epic severity and impersonality; to lofty meditation, as in "Dover Beach"; and to sustained magnificence and richness, as in "The Scholar Gipsy" and "Thyrsis"—where he wields an intricate stanza form without a stumble.

In 1857, assisted by the vote of his godfather (and predecessor) John Keble, Arnold was elected to the Oxford chair of poetry, which he held for 10 years. It was characteristic of him that he revolutionized this professorship. The keynote was struck in his inaugural lecture: "On the Modern Element in Literature," "modern" being taken to mean not merely "contemporary" (for Greece was "modern"), but the spirit that, contemplating the vast and complex spectacle of life, craves for moral and intellectual "deliverance." Several of the lectures were afterward published as critical essays, but the most substantial fruits of his professorship were the three lectures *On Translating Homer* (1861)—in which he recommended Homer's plainness and nobility as medicine for the modern world, with its "sick hurry and divided aims" and condemned Francis Newman's recent translation as ignoble and eccentric—and the lectures *On the Study of Celtic Literature* (1867), in which, without much knowledge of his subject or of anthropology, he used the Celtic strain as a symbol of that which rejects the despotism of the commonplace and the utilitarian.

Arnold as critic. It is said that when the poet in Arnold died, the critic was born; and it is true that from this time onward he turned almost entirely to prose. Some of the leading

ideas and phrases were early put into currency in *Essays in Criticism* (First Series, 1865; Second Series, 1888) and *Culture and Anarchy*. The first essay in the 1865 volume, "The Function of Criticism at the Present Time," is an overture announcing briefly most of the themes he developed more fully in later work. It is at once evident that he ascribes to "criticism" a scope and importance hitherto undreamed of. The function of criticism, in his sense, is "a disinterested endeavour to learn and propagate the best that is known and thought in the world, and thus to establish a current of fresh and true ideas." It is in fact a spirit that he is trying to foster, the spirit of an awakened and informed intelligence playing upon not "literature" merely but theology, history, art, science, sociology, and politics, and in every sphere seeking "to see the object as in itself it really is."

In this critical effort, thought Arnold, England lagged behind France and Germany, and the English accordingly remained in a backwater of provinciality and complacency. Even the great Romantic poets, with all their creative energy, suffered from the want of it. The English literary critic must know literatures other than his own and be in touch with European standards. This last line of thought Arnold develops in the second essay, "The Literary Influence of Academies," in which he dwells upon "the note of provinciality" in English literature, caused by remoteness from a "centre" of correct knowledge and correct taste. To realize how much Arnold widened the horizons of criticism requires only a glance at the titles of some of the other essays in *Essays in Criticism* (1865): "Maurice de Guérin," "Eugénie de Guérin," "Heinrich Heine," "Joubert," "Spinoza," "Marcus Aurelius"; in all these, as increasingly in his later books, he is "applying modern ideas to life" as well as to letters and "bringing all things under the point of view of the 19th century."

The first essay in the 1888 volume, "The Study of Poetry," was originally published as the general introduction to T.H. Ward's anthology, *The English Poets* (1880). It contains many of the ideas for which Arnold is best remembered. In an age of crumbling creeds, poetry will have to replace religion. More and more, we will "turn to poetry to interpret life for us, to console us, to sustain us." Therefore we must know how to distinguish the best poetry from the inferior, the genuine from the counterfeit; and to do this we must steep ourselves in the work of the acknowledged masters, using as "touchstones" passages exemplifying their "high seriousness," and their superiority of diction and movement.

The remaining essays, with the exception of the last two (on Tolstoy and Amiel), all deal with English poets: Milton, Gray, Keats, Wordsworth, Byron, and Shelley. All contain memorable things, and all attempt a serious and responsible assessment of each poet's "criticism of life" and his value as food for the modern spirit. Arnold has been taken to task for some of his judgments and omissions: for his judgment that Dryden and Pope were not "genuine" poets because they composed in their wits instead of "in the soul"; for calling Gray a "minor classic" in an age of prose and spiritual bleakness; for paying too much attention to the man behind the poetry (Gray, Keats, Shelley); for making no mention of Donne; and above all for saying that poetry is "at bottom a criticism of life." On this last point it should be remembered that he added "under the conditions fixed. . . by the laws of poetic truth and poetic beauty," and that if by "criticism" is understood (as Arnold meant) "evaluation," Arnold's dictum is seen to have wider significance than has been sometimes supposed.

Culture and Anarchy is in some ways Arnold's most central work. It is an expansion of his earlier attacks, in "The Function of Criti-

cism" and "Heinrich Heine," upon the smugness, philistinism, and mammon worship of Victorian England. Culture, as "the study of perfection," is opposed to the prevalent "anarchy" of a new democracy without standards and without a sense of direction. By "turning a stream of fresh thought upon our stock notions and habits," culture seeks to make "reason and the will of God prevail."

Arnold's classification of English society into Barbarians (with their high spirit, serenity, and distinguished manners and their inaccessibility to ideas), Philistines (the stronghold of religious nonconformity, with plenty of energy and morality but insufficient "sweetness and light"), and Populace (still raw and blind) is well known. Arnold saw in the Philistines the key to the whole position; they were now the most influential section of society; their strength was the nation's strength, their crudeness its crudeness: Educate and humanize the Philistines, therefore. Arnold saw in the idea of "the State," and not in any one class of society, the true organ and repository of the nation's collective "best self." No summary can do justice to this extraordinary book; it can still be read with pure enjoyment, for it is written with an inward poise, a serene detachment, and an infusion of mental laughter, which make it a masterpiece of ridicule as well as a searching analysis of Victorian society. The same is true of its unduly neglected sequel, *Friendship's Garland* (1871).

Religious writings. Lastly Arnold turned to religion, the constant preoccupation and true centre of his whole life, and wrote *St. Paul and Protestantism* (1870), *Literature and Dogma* (1873), *God and the Bible* (1875), and *Last Essays on Church and Religion* (1877). In these books, Arnold really founded Anglican "modernism." Like all religious liberals, he came under fire from two sides: from the orthodox, who accused him of infidelity, of turning God into a "stream of tendency" and of substituting vague emotion for definite belief; and from the infidels, for clinging to the church and retaining certain Christian beliefs of which he had undermined the foundations. Arnold considered his religious writings to be constructive and conservative. Those who accused him of destructiveness did not realize how far historical and scientific criticism had already riddled the old foundations; and those who accused him of timidity failed to see that he regarded religion as the highest form of culture, the one indispensable without which all secular education is in vain. His attitude is best summed up in his own words (from the preface to *God and the Bible*): "At the present moment two things about the Christian religion must surely be clear to anybody with eyes in his head. One is, that men cannot do without it; the other, that they cannot do with it as it is." Convinced that much in popular religion was "touched with the finger of death" and convinced no less of the hopelessness of man without religion, he sought to find for religion a basis of "scientific fact" that even the positive modern spirit must accept. A reading of Arnold's *Note Books* will convince any reader of the depth of Arnold's spirituality and of the degree to which, in his "buried life," he disciplined himself in constant devotion and self-forgetfulness.

Arnold died suddenly, of heart failure, in the spring of 1888, at Liverpool and was buried at Laleham, with the three sons whose early loss had shadowed his life. (B.W./Ed.)

MAJOR WORKS. *Poetical works.* *Alaric at Rome* (1840; Rugby School prize poem); *Cromwell* (1843; Newdigate Prize poem); *The Strayed Reveller, and Other Poems.* By A. (1849); *Empedocles on Etna, and Other Poems.* By A. (1852); *Poems* (1853; including "Sohrab and Rustum," "The Forsaken Mermaid," and "The Scholar Gipsy"); *Poems, Second Series* (1855); *Merope* (1858; classical tragedy); *New Poems* (1867; including "Thyrsis" and "Dover Beach").

Prose works. *The Popular Education of France with Notices of That of Holland and Switzerland* (1861; revised text of the 1860 report prepared by Arnold for the Education Commission); *On Translating Homer* (1861); *On Translating Homer: Last Words* (1862); *A French Eton: or, Middle Class Education and the State* (1864); *Essays in Criticism* (1865; including "The Function of Criticism at the Present Time," "The Literary Influence of Academies," "Maurice de Guérin," "Eugénie de Guérin," "Heinrich Heine," "Joubert," "Spinoza," and "Marcus Aurelius"); *On the Study of Celtic Literature* (1867); *Schools and Universities on the Continent* (1868; reprinted from Arnold's report *On Secondary Education in Foreign Countries* of 1866); *Culture and Anarchy* (1869); *St. Paul and Protestantism* (1870); *Friendship's Garland* (1871); *Literature and Dogma* (1873); *God and the Bible* (1875); *Last Essays on Church and Religion* (1877); *Mixed Essays* (1879); *Irish Essays* (1882); *Discourses in America* (1885); *Essays in Criticism, Second Series* (1888; including "The Study of Poetry" and essays on Milton, Thomas Gray, Keats, Wordsworth, Byron, Shelley, Tolstoy, and Amiel); *Reports on Elementary Schools 1852-1882*, edited by Sir Francis Sandford (1889; new edition with added material and introduction by F.S. Marvin, 1908).

BIBLIOGRAPHY. A new and complete edition of Arnold's poems was published in "Oxford Standard Authors Series" (1950), ed. by C.B. Tinker and H.F. Lowry. *Arnold's Letters (1848-1888)*, collected and arranged by G.W.E. Russell (1895; 2nd ed., 1901); Arnold Whitridge (ed.), *Unpublished Letters* (1923); *Letters to Arthur Hugh Clough*, with an introductory study by H.F. Lowry (ed.) (1932, reprinted 1968). There is a complete edition (literary contents) of *The Note-Books of Matthew Arnold*, ed. by H.F. Lowry, K. Young, and W.H. Dunn (1952). An edition deluxe of Arnold's complete *Works*, 15 vol. (1903-04), includes a bibliography by T.B. Smart. For a more recent bibliography, see T.G. Ehrsam and R.H. Deily (comps.), *Bibliographies of Twelve Victorian Authors* (1936; suppl. by J.G. Fucilla in *Modern Philology*, 37:89-96, 1939).

It was Arnold's expressed desire that his biography should not be written; there are, however, a number of monographs and biographical-critical works, among them Lionel Trilling, *Matthew Arnold* (1939), the best full-length study; J. Dover Wilson, *Leslie Stephen and Matthew Arnold As Critics of Wordsworth* (1939); Sir E.K. Chambers, *Matthew Arnold: A Study* (1947); J.D. Jump, *Matthew Arnold*, "Men and Books Series" (1955); G. Robert Stange, *Matthew Arnold: The Poet As Humanist* (1967).

Arnold, Samuel (b. Aug. 10, 1740, London—d. Oct. 22, 1802, London), composer whose 36-volume edition of Handel (1786-97), although shown defective by later scholarship, was the earliest attempt to publish a composer's complete works.

Samuel Arnold, detail of a pencil drawing by G. Dance, 1795; in the National Portrait Gallery, London
By courtesy of the National Portrait Gallery, London

Educated at Chapel Royal, Arnold became composer to Covent Garden Theatre; his first annual production was *The Maid of the Mill* (1765). Subsequent positions were as music director of the Theatre Royal in the Haymarket (1777), organist and composer to the Chapel Royal (1783), and organist at Westminster Abbey (1793). His compositions in-

clude sonatas, symphonies, and oratorios, as well as ballad operas, farces, and pantomimes. His *Cathedral Music* (1790), a collection of service music, was an important supplement to William Boyce's *Cathedral Music*.

Arnold, Thomas (b. June 13, 1795, East Cowes, Isle of Wight, Eng.—d. June 12, 1842, Rugby, Warwickshire), educator who, as headmaster of Rugby School, had much influence on public school education in England. He was the father of the poet and critic Matthew Arnold.

Thomas Arnold was educated at Winchester and at Corpus Christi College, Oxford. He was elected a fellow of Oriel College, Oxford, in 1815. After ordination and marriage he settled at Laleham, Middlesex, in 1819 as a tutor to

Thomas Arnold, detail of an engraving by H. Cousins, 1840, after an oil painting by Thomas Phillips

university entrants. In 1828 he became headmaster of Rugby and gradually raised it to the rank of a great public school.

Arnold was not an innovator in teaching method; his aim was to reform Rugby by making it a school for gentlemen. He used prefects more fully than any previous headmaster. Under the prefect system the older boys served as house monitors to keep discipline among the younger boys; this system was adopted in most English secondary schools. The Arnold tradition spread to other schools through Rugby pupils and masters, and many schools established after Arnold's death were modelled on Rugby.

Arnold was the author of five volumes of sermons, an edition of Thucydides, and a three-volume history of Rome. Arthur Penrhyn Stanley's *Life and Correspondence of Dr. Arnold*, 2 vol. (1844), was followed by Sir Joshua Fitch's *Thomas and Matthew Arnold, and Their Influence on English Education* (1897). Lytton Strachey included a sketch of Arnold in *Eminent Victorians* (1918).

Arnold Arboretum of Harvard University, major botanical research centre famous for its collection of ornamental trees and shrubs from the Orient. Founded in 1872 in Jamaica Plain, Boston, the 262-acre (106-hectare) arboretum has acquired and cultivated more than 6,000 species of woody plants. Of special importance are its Oriental cherries, forsythias, lilacs, honeysuckles, oaks, magnolias, conifers, dwarf evergreens, and Asiatic trees. The arboretum maintains an herbarium comprising more than 1,000,000 reference specimens, principally from eastern Asia and New Guinea. It also publishes the *Journal of the Arnold Arboretum* and *Arnoldia*.

Arnoldson, Klas Pontus (b. Oct. 27, 1844, Göteborg, Swed.—d. Feb. 20, 1916, Stock-

holm), politician who figured prominently in solving the problems of the Norwegian-Swedish Union. He was the cowinner (with Fredrik Bajer) of the Nobel Peace Prize in 1908.

Arnoldson became a railway clerk and rose to stationmaster (1871–81) but then left the railway to devote himself entirely to politics. In 1881 he was elected to the Riksdag, the Swedish parliament. A passionately devoted pacifist, Arnoldson supported the neutrality of the Nordic countries and in 1883 helped to found the Swedish Association for Peace and Conciliation.

From 1890, when the conflict between Norway and Sweden was critical, Arnoldson made use of all his powers, including his gift for inspiring oratory, in an attempt to shape public opinion in both countries in favour of a peaceful settlement. In 1905 he saw the result of his work in the mutually agreed dissolution of the union.

Arnolfo di Cambio (b. c. 1245, Colle di Val d'Elsa [Italy]—d. 1301/10, Florence), Italian sculptor and architect whose works embody the transition between the late Gothic and Renaissance architectural sensibilities.

Arnolfo studied painting under Cimabue and sculpture under Nicola Pisano. He served as assistant to Pisano in 1265–68 in the production of the pulpit for the Siena Cathedral. Arnolfo went to Rome in 1277 as the protégé of Charles of Anjou, king of Sicily, at which time he may have produced the monument of Cardinal Annibaldi in the Church of San Giovanni in Laterano (now disassembled) and the tomb of Pope Adrian V in the Church of San Francesco, Viterbo. In 1281 he executed a fountain at Perugia, figures from which survive in the National Gallery of Umbria. The following year he constructed a monument to Cardinal de Braye (d. 1282) in San Domenico at Orvieto and subsequently designed altar canopies for San Paolo Fuori le Mura (1285) and Santa Cecilia in Trastevere (1293) in Rome.

In 1296 Arnolfo returned to Florence to undertake his most important commission, the design of the Duomo (the cathedral of Florence) and the carving of statues for its facade (now in the Museum of the Duomo). Other buildings attributed to him are the Palazzo Vecchio (Palazzo della Signoria), the Church of Santa Croce, and the choir of the Badia (Benedictine abbey).

The structural and decorative elements of Santa Croce and the Duomo have a unity, balance, and a lightness of movement that demonstrate Arnolfo's complete mastery of the late 13th-century Gothic architectural vocabulary. His sculptures have a strong sense of volume that shows the influence on him of antique Roman models.

Arnoul (French personal name): *see under Arnulf*.

Arnsberg, *Regierungsbezirk* (administrative district), east-central North Rhine–Westphalia *Land* (state), western Germany. Arnsberg is bordered by Hesse *Land* to the east, Rhineland-Palatinate *Land* to the southwest, and the *Regierungsbezirke* of Köln and Düsseldorf to the west and Münster and Detmold to the north. The largest of five districts in North Rhine–Westphalia, it occupies an area of 3,088 square miles (7,998 square km) and is coextensive with the southern portion of the larger historic region of Westphalia (*q.v.*). Arnsberg district was created in 1816 and takes its name from that of its administrative seat.

The level, loess-covered Hellweg plateau, a historic routeway and zone of early settlement, runs east-west across northern Arnsberg

between the Lippe (north) and Ruhr (south) rivers. The heavily industrialized Ruhr urban complex and the immense Ruhr bituminous coalfield extend east from Düsseldorf *Regierungsbezirk* across the western Hellweg to Hamm. Five cities in the Ruhr complex of Arnsberg—Dortmund (the largest city in the district), Bochum, Herne, Hamm, and Witten—have populations of more than 100,000. Population densities in these urban areas often exceed 7,800 persons per square mile (3,000 per square km). Dortmund is a major centre of heavy iron and steel processing. It is also a major manufacturer of heavy machine tools and is famous for its breweries. The eastern Hellweg is a fertile agricultural region centred on the Soester Plain. Sugar beets, vegetables, and fruits are the chief crops.

The Sauerland, the most northerly plateau of the Middle Rhine Highlands, comprises the southern three-quarters of Arnsberg. This region is bounded on the north by the Ruhr River and its tributary the Möhne and on the south by the Sieg River and the Wester Forest (mountains). The chief city of the highly industrialized Sieg valley is Siegen, important for its production of special quality iron and steel. Northeast of Siegen the upwarped ridge of the heavily forested Rothaar Hills rises to 2,759 feet (841 m) in altitude at the heath-covered Kahler Asten and forms a natural frontier with Hesse. From the Rothaar Hills the Sauerland plateau slopes gradually to the north and northwest and is increasingly dissected by the tributaries of the Ruhr and Rhine rivers. Numerous dams and reservoirs in the deep river valleys supply water to the Ruhr urban industrial complex. In the area of the former northwestern County of Mark, many medium and small towns specialize in the manufacture of machinery, hardware, and electrical equipment. Pasture farming and forestry occur in some of the lower valleys, and tourism is growing at a number of health and winter sports resorts, including Winterberg and Schmalleberg.

The majority of the population of Arnsberg *Regierungsbezirk* are descendants of the western Saxons and speak a Low German dialect. There is also a strong Frankish influence in regions of the Sauerland where the Riparian Franconian dialect is often spoken. More than 50 percent of the people are Protestants, and about 40 percent are Roman Catholics. The predominant rural settlement pattern is one of dispersed farmsteads and small hamlets of half-timbered houses. Higher education in the district is centred at universities in Bochum, Dortmund, and Siegen. Pop. (1989 est.) 3,634,467.

Arnsberg, city, North Rhine–Westphalia *Land* (state), western Germany. It lies along a loop of the Ruhr River, east of Iserlohn. Situated between wooded mountains and known as the Pearl of the Sauerland (southern land of Westphalia), it is a popular spa and summer resort. Arnsberg originated in the 11th century around a castle of the counts of Werl and was chartered in 1238. The countship of Arnsberg was under the jurisdiction of the electors of Cologne after the 12th century and was the main seat of the Westphalian fehmic courts (or *Vehmgericht*; medieval secret tribunals that usurped many functions of government). The ruins of the old castle and the 13th–14th-century church of Wedinghausen Abbey are notable.

Industries include paper milling, woodworking, manufacture of metalware, and brewing. Pop. (1989 est.) 73,912.

Arnstadt, city, Thuringia *Land* (state), central Germany. It lies along the Gera River, at the northern edge of the Thuringian Forest, just southwest of Erfurt city. First mentioned in 704 and chartered in 1266, Arnstadt was bought in 1306 from the abbey of Hersfeld by the counts of Schwarzburg, who lived there un-

til 1716. Their palace, Monplaisir (1703–07), survives, and the 12th–14th-century Church of Our Lady (Liebfrauenkirche) has a number of Schwarzburg graves. Several members of the Bach family worked in Arnstadt in the 17th century, including J.S. Bach, who was organist of Boniface (now called Bach) Church from 1703 to 1707. The town hall dates from 1583–85. North of the city rise the castle-crowned peaks, the Three Alike (Drei Gleichen).

Noted for its glove-manufacturing industries, Arnstadt also has glassworks, wood-finishing works, engineering works, leather-processing works, and foundries. There are many holiday and convalescent homes in the city and vicinity. Pop. (1989 est.) 30,482.

Arnulf, also called **ARNULF OF CARINTHIA**, German **ARNULF VON KÄRNTEN** (d. Dec. 8, 899), duke of Carinthia who deposed his uncle, the Holy Roman emperor Charles III the Fat, and became king of Germany, later briefly wearing the crown of the emperor.

Arnulf, seal, 9th century; in the Bavarian National Museum, Munich

By courtesy of the Bayerisches Nationalmuseum, Munich, photograph, Foto Marburg

Arnulf was the illegitimate son of Charles the Fat's eldest brother, Carloman, who was king of Bavaria. Arnulf inherited the march of Carinthia from his father but was excluded from the succession to the kingdom on Carloman's death. Arnulf maintained and consolidated his frontiers, though in constant tension with the Moravian kingdom of Svatopluk. In November 887, at Frankfurt, the East Frankish magnates revolted against the incompetent emperor Charles the Fat, who since 885 had ruled the reunited Carolingian empire. Arnulf was elected king of the East Franks, and Charles yielded without a struggle. The West Franks, Burgundy, and Italy refused to recognize Arnulf, however, and elected new kings from their own nobility. The Carolingian empire thus finally disintegrated.

Arnulf's base of operations remained in Bavaria, but he successfully defended his authority as German king in Lotharingia (now Lorraine), and he even maintained a loose feudal authority over the other kings. He was an energetic ruler whose suzerainty was acknowledged even by the sons of Svatopluk after their father's death in 894. In 891 Arnulf inflicted a crushing defeat on the Vikings at the Dyle River, north of Brussels, and their raids up the Rhine River consequently ended in 892. Arnulf also gave his son Zwentibold the crown of Lotharingia.

The king of Italy, Guy of Spoleto, had had himself crowned Holy Roman emperor by Pope Stephen V. In 893, after reluctantly crowning Guy's son, Lambert, as coemperor, the new pope, Formosus, sought help against Guy from Arnulf, who accordingly invaded Italy in 894. Arnulf withdrew from Italy later that same year, but, after Guy's death in 894, Pope Formosus urged Arnulf to invade Italy once more. Crossing the Alps in October 895, Arnulf, although handicapped by bad weather, illness, and the absence of expected support from Berengar of Friuli, appeared before the walls of Rome. Rome fell, and in St. Peter's

on Feb. 22, 896, Arnulf was crowned emperor by Formosus, who declared Lambert deposed. After a two-week stay in the city, Arnulf marched south to settle accounts with his rival at Spoleto, but en route he was suddenly taken ill and had to return to Germany. Lambert remained emperor despite the pope's action.

The last three years of Arnulf's life, during which his illness continued, saw Germany invaded by Moravians and Hungarians, Lotharingia in revolt against Zwentibold, Italy lost, and France free of Arnulf's influence.

Arnulf I, byname ARNULF THE GREAT, or THE ELDER, French ARNOUL LE GRAND, or LE VIEUX, Dutch ARNULF DE GROTE, or DE OUDE (b. c. 900—d. March 27, 965), count of Flanders (918–958, 962–965) and son of Baldwin II.

On his father's death in 918, the inherited lands were divided between Arnulf and his brother Adolf, but the latter survived only a short time, and Arnulf succeeded to the whole inheritance. His reign was filled with warfare against the Norsemen, and he took an active part in the struggles in Lorraine between the emperor Otto I and Hugh Capet.

In 958 Arnulf placed the government in the hands of his son Baldwin (Baldwin III), and the young man, though his reign was a very short one, did a great deal for the commercial and industrial progress of the country, establishing the first weavers and fullers at Ghent and instituting yearly fairs at Ypres, Bruges, and other places. On Baldwin III's death in 962 the old count, Arnulf I, resumed control and spent the few remaining years of his life in securing the succession of his grandson Arnulf II the Younger (reigned 965–988).

Arnulf of Metz, Saint, French SAINT ARNOUL DE METZ (b. c. 580, near Nancy [France]—d. July 18, 640?, Remiremont; feast day August 16 or 19), bishop of Metz and, with Pepin I, the earliest known ancestor of Charlemagne.

A Frankish noble, Arnulf gave distinguished service at the Austrasian court under Theudebert II (595–612). In 613, however, with Pepin, he led the aristocratic opposition to Brunhild that led to her downfall and to the reunification of Frankish lands under Chlotar II. About the same year, he became bishop.

From 623, again with Pepin, now mayor of the Austrasian palace, Arnulf was adviser to Dagobert I, before retiring (629?) to become a hermit. Arnulf's son Ansegisel married Pepin's daughter Begga; the son of this marriage, Pepin II, was Charlemagne's great-grandfather.

Arochukwu, also spelled AROCHUKU, town, Abia state, southern Nigeria. It lies along the road from Calabar to Umuahia. Arochukwu was the headquarters of the Aro, an Igbo (Ibo) subgroup that dominated southeastern Nigeria in the 18th and 19th centuries. It was the seat of the sacred Chuku shrine, the source of a much-feared oracle (called Long Juju by the Europeans) that acted as a judge for the Igbo supreme deity (Chuku) and that, as used by Aro middlemen, served as the major recruiter for the slaves sent to the port of Bonny (Ubani) for sale. The shrine and power of the oracle were destroyed by the British in their campaigns against the Aro people in 1900–02. Arochukwu is now a market centre and the site of a teacher-training college.

aromatic compound, any of a large class of chemical compounds whose molecular structure includes one or more planar rings of atoms joined by covalent bonds of two different kinds. The term aromatic was first applied about 1860 to a group of hydrocarbons isolated from coal tar and distinguished by their odours, which are much stronger than those of other groups of hydrocarbons; in chemistry, aromaticity has come to denote the chemical

behaviour, especially low reactivity, derived from the electronic structure of this class of molecules.

Many aromatic compounds are relatives of benzene (*q.v.*), an organic compound that contains a ring of six carbon atoms; in others, atoms of other elements, especially nitrogen, replace one or more of the carbon atoms. Every atom in the ring shares a pair of electrons with each of its two neighbours: each of these electron pairs is concentrated between the two atoms, forming a bond denoted σ (sigma). In addition, two regions, of high electron density, parallel to the ring formed by the atoms, constitute a system of π - (pi) bonds associated not with any pair of atoms but with the entire ring. The essential aspect of aromatic compounds is the number of electrons in the π -bond system, rather than the number or identity of the atoms in the ring. Most commonly, there are six electrons in the system, but there may be any number given by the expression $4n + 2$, in which $n = 1, 2, 3$, etc.

aron, also called ARON HA-QODESH (Judaism): *see ark.*

Aron, Raymond (-Claude-Ferdinand) (b. March 14, 1905, Paris, France—d. Oct. 17, 1983, Paris), French sociologist, historian, and political commentator known for his skepticism of ideological orthodoxies.

The son of a Jewish jurist, Aron obtained his doctorate in 1930 from the École Normale Supérieure with a thesis on the philosophy of history. He was a professor of social philosophy at the University of Toulouse when World War II broke out in 1939, upon which he joined the French air force. After the fall of France he joined the Free French forces of General Charles de Gaulle in London and edited their newspaper, *La France Libre* ("Free France"), from 1940 to 1944. On his return to France he became a professor at the École Nationale d'Administration, and from 1955 to 1968 he was professor of sociology at the Sorbonne. From 1970 he was professor at the Collège de France. Throughout his life Aron was active as a journalist, and in 1947 he became a highly influential columnist for *Le Figaro*, a position he held for 30 years. He left *Le Figaro* in 1977, and from then until his death he wrote a political column for the weekly magazine *L'Express*.

Aron upheld a rationalist humanism that was often contrasted with the Marxist existentialism of his great contemporary, Jean-Paul Sartre. Though his range was slightly narrower than Sartre's and his international renown less general, Aron enjoyed a position of intellectual authority among French moderates and conservatives that almost rivaled Sartre's on the left. Among Aron's most influential works were *L'Opium des intellectuels* (1955; *The Opium of the Intellectuals*), which criticized left-wing conformism and the totalitarian tendencies of Marxist regimes. Aron himself became a strong supporter of the Western alliance. In *La Tragédie algérienne* (1957; "The Algerian Tragedy") he voiced his support for Algerian independence, and in *République impériale: Les États-Unis dans le monde, 1945–1972* (1973; *The Imperial Republic: The United States and the World, 1945–1973*), he attacked the unthinking hostility aimed at the United States by French leftists. A continuing theme in his writings was the subject of violence and war, as evidenced in such works as *Paix et guerre entre les nations* (1962; *Peace and War*) and his books on the Prussian military theorist Carl von Clausewitz. Aron also wrote an influential history of sociology entitled *Les Étapes de la pensée sociologique* (1967; *Main Currents in Sociological Thought*). His memoirs were published in 1983.

Aroostook War (1838–39), bloodless conflict over the disputed boundary between the

U.S. state of Maine and the British Canadian province of New Brunswick. The peace treaty of 1783 ending the U.S. War of Independence had left unclear the location of a supposed "highlands," or watershed, dividing the two areas. Negotiators from Britain and the United States in subsequent years failed to come to an agreement, and the matter was referred to the king of The Netherlands, who in 1831 rendered a decision that the citizens of Maine objected to strenuously, forcing the U.S. Senate to reject it.

Meanwhile, settlers from New England and lumbermen from Canada were moving into the disputed Aroostook area, and in 1838–39 the conflict warmed up, with officials and bands of men from both sides making arrests and taking prisoners of "trespassers." In March 1839 British troops from Quebec reached Madawaska, the American sector of Aroostook; and the Maine legislature immediately voted \$800,000, calling for 10,000 volunteer militiamen, who, within a week, were dispatched to Aroostook. The U.S. Congress voted for 50,000 men and \$10,000,000; and General Winfield Scott was ordered to Augusta, Maine, by President Martin Van Buren to keep the peace. On March 21, 1839, he and the British negotiator, Sir John Harvey, arranged a truce and a joint occupancy of the territory in dispute until a satisfactory settlement could be reached. The boundary was later settled by the Webster-Ashburton Treaty (*q.v.*) of 1842.

Arosa, Alpine village, health resort, and winter sports centre, Graubünden canton, eastern Switzerland, on the Plessur River. The village, at an elevation of 5,689 feet (1,734 m), stretches along a wooded valley holding two small lakes, the Untersee and the Obersee, that are used for fishing, swimming, and boating in the summer. Arosa is noted as a fashionable winter-sports centre, particularly for horse racing on ice and snow. The ski slopes above the tree line are accessible by a network of ski lifts and linking ski runs. A cable car runs up the nearby Weisshorn (8,704 feet), and gondola cars reach up the Hörnli (8,200 feet). Curling, ice skating, and ice hockey are also popular. Arosa lies at the end of a road and rail spur from Chur. Pop. (1990) 2,850.

Arouet, François-Marie: *see* Voltaire.

arousal (psychology): *see* activation.

Arp, Halton Christian (b. March 21, 1927, New York, N.Y., U.S.), American astronomer noted for challenging the theory that red shifts of quasars indicate their great distance.

Arp received a bachelor's degree from Harvard University in 1949 and a Ph.D. from the California Institute of Technology in 1953. He subsequently accepted a research fellowship to conduct postdoctoral studies at the nearby Hale Observatories (now the Mt. Wilson and Palomar Observatories). After he worked as a research associate at Indiana University from 1955 to 1957, Arp returned to Mt. Wilson, securing a post as an assistant astronomer on the observatory staff. He was appointed astronomer there in 1965.

Arp became skeptical about the distance of quasars when he noticed that some of the galaxies that he had included in his *Atlas of Peculiar Galaxies* (1966) seemed to lie in the vicinity of quasars. Using photographic evidence, Arp tried to prove that the low-red-shift galaxies and the high-red-shift quasars not only appear close together but also actually are connected by gaseous bridges, an impossibility if the quasars are billions of light-years further away than the galaxies. Arp theorized that the nuclei of galaxies may explode, ejecting quasars with a velocity great enough to account for their red shifts.

Arp, Jean, also called HANS ARP (b. Sept. 16, 1887, Strassburg, Ger. [now Strasbourg, Fr.]—d. June 7, 1966, Basel, Switz.), French sculptor, painter, and poet who was one of the leaders of the European avant-garde in the arts during the first half of the 20th century.

First trained as an artist in his native Strasbourg, he later studied in Weimar, Ger., and at the Académie Julian in Paris. In 1912 he went to Munich, where, through his friend Wassily Kandinsky, he became briefly associated with Der Blaue Reiter. He returned to Paris in 1914 and became acquainted with the artists Modigliani, Picasso, and Robert Delaunay, as well as with the writer Max Jacob. During World War I he took refuge in Zü-

rich, where he became one of the founders of the Dada (*q.v.*) movement. It was there that he produced his first painted reliefs. After the war he lived in Germany until 1924, when he and his wife, the artist Sophie Taeuber, whom he had married in 1921, settled near Paris in the town of Meudon. During the 1920s he was associated with the Surrealists, and in 1930 he was a member of the Cercle et Carré group. This was also the year in which he made his first *papiers déchirés* ("torn papers"). In 1931 he participated in the Abstraction-Création movement. During World War II he again went to live in Zürich, where his wife died in 1943. While in Switzerland he did his first *papiers froissés* ("crumpled papers"). After the war Arp returned to Meudon, where he continued his experiments with abstract form and colour and wrote poetry. *Arp on Arp: Poems, Essays,*

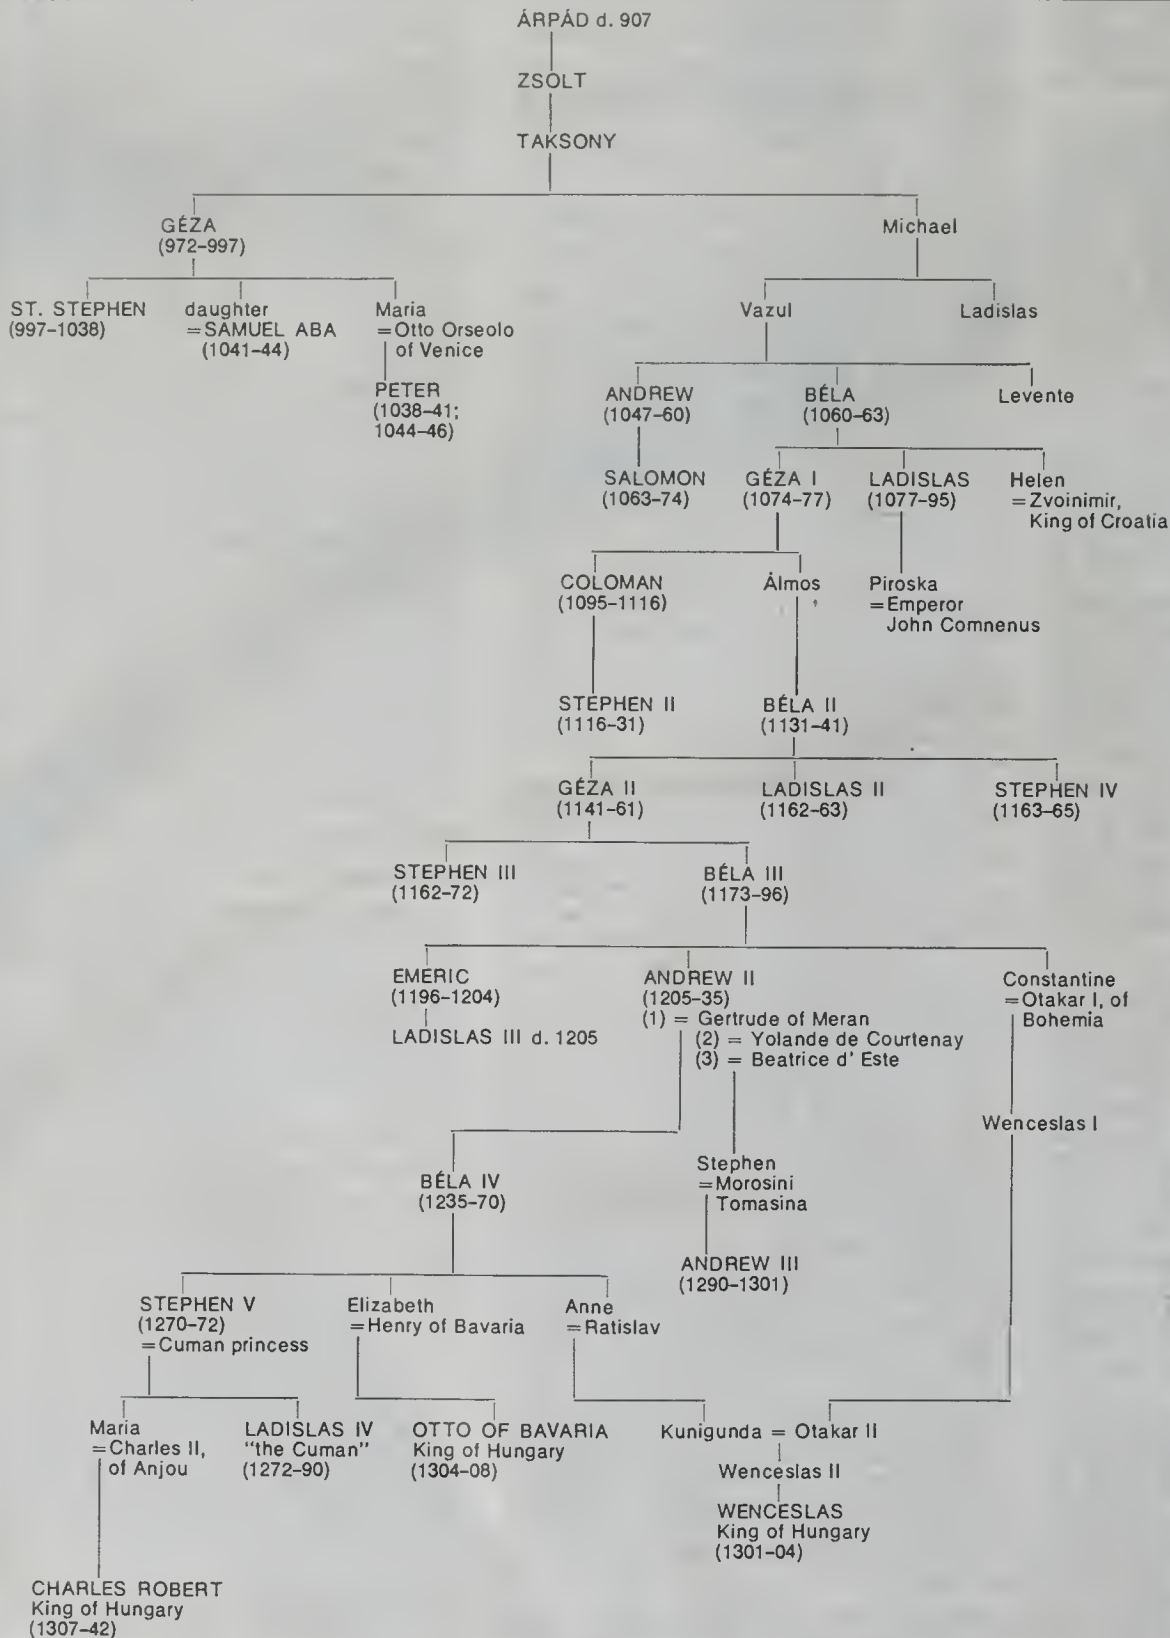

Memories by Jean Arp (1972) and *Arp's Collected French Writings* (1974) were edited by Marcel Jean.

Arpad, also called TALL RIF'AT, ancient city in northwestern Syria. Arpad is frequently mentioned in the Old Testament and in Assyrian texts.

Coming under Assyrian influence in the 9th century BC, Arpad regained its independence in 754, and it successfully sided with Sardur II of Urartu until the Assyrian king Tiglath-pileser III defeated both Urartu and Arpad. Tiglath-pileser made Arpad the capital of a province that included the western half of northern Syria. After an unsuccessful revolt against Sargon II in 720 BC, the city remained loyal to Assyria.

Árpád DYNASTY, rulers of Hungary from the late 9th century until 1301, under whom

Árpád dynasty

the Hungarian nation was transformed from a confederation of Hungarian tribes into a powerful state of east-central Europe. The dynasty was named after Árpád (d. 907), who was chosen by seven Hungarian tribes to lead them westward from their dwelling place on the Don River (889). Having crossed the Carpathian Mountains (c. 896), the Hungarians settled on the Pannonian, or Hungarian, Plain and for the next half century raided their neighbours and collected booty. But, after their defeat by Emperor Otto I (Battle of Lechfeld; Aug. 10, 955), they became less belligerent. During the reign of Géza (972–997), Árpád's great-grandson, they established cordial relations with the West and acknowledged the authority of their king before the authority of their chieftains.

Stephen (István; reigned 997–1038), expanding upon his father's accomplishments, officially converted his people to Christianity in the Western Church (1000), extended his control over Transylvania (1003), and replaced the tribal political structure with a system of counties, each one ruled by an appointed "count." Furthermore, by claiming all territory not occupied by freemen as property of the crown, Stephen laid the basis of the Hungarian monarchy's future wealth and power.

Although Stephen's successors were engaged in numerous struggles for succession, not only were they able to resist successfully the efforts of the Holy Roman emperor to dominate Hungary (especially in 1063 and 1074), but also King Ladislas (László; reigned 1077–95) and King Coloman (Kálmán; reigned 1095–1116) were able to extend Hungary's control over Croatia. In the 12th century it was the Byzantine emperor who gained significant influence in Hungary by intervening in the succession struggles of Ladislas II (reigned 1162–63) and Stephen IV (reigned 1163–65) against their nephew Stephen III (reigned 1162–72). But Béla III (reigned 1173–96), brother and successor of Stephen III, reestablished the independence and authority of the Hungarian monarchy.

During Béla's reign the Árpád dynasty achieved the peak of its power. Having derived great wealth from its crown lands, the dynasty gained control of Serbia and Galicia and made Hungary a large and formidable power in east-central Europe. After Béla's death the monarchy suffered a decline. Emeric (Imre; reigned 1196–1204) and his brother Andrew II (Endre; reigned 1205–35), by making lavish land grants to their supporters, reduced the source of the monarchy's wealth and power. Andrew further weakened the monarchy by guaranteeing the liberties of the nobles (see Golden Bull of 1222) and allowing them to gain control of the county governments.

After the Mongols invaded and ravaged Hungary (1241–42), Béla IV (reigned 1235–70) encouraged reconstruction, but in the process he was forced to grant extensive privileges and authority to local magnates and thereby reduce the royal authority. His son Stephen V (reigned 1270–72) married a Cuman princess and was succeeded by their son Ladislas IV the Cuman (reigned 1272–90), and the prestige of the royal house declined even more. Ladislas left no legitimate heir; he was succeeded by Andrew III (reigned 1290–1301), grandson of Andrew II. But Andrew III also died without leaving an heir, and the Árpád dynasty, whose power had already significantly diminished, became extinct. Thereafter, the Hungarian throne became the object of contention among several foreign royal houses related by marriage to the House of Árpád.

Arpino, ancient (Latin) ARPINUM, town, Frosinone provincia, Lazio (Latium) regione, central Italy, on two hills 1,476 feet (450 m) above sea level, just east of the city of Frosinone. The town originated as a stronghold of the Volsci, who entered the area during the 5th century BC. During the

4th century BC it was held for a time by the Samnites, and it was finally conquered by the Romans in 305 BC, and the Roman general Gaius Marius was born there. In the Middle Ages it was sacked by the Lombards, the Saracens, and the Hungarians; it passed to the papacy in 1215. The remains of the imposing cyclopean walls of the Volscian period, restored and added to in Samnite, Roman, and medieval times, surround the town. The 15th-century churches of San Michele and San Andrea contain paintings by the Mannerist Giuseppe Cesari, commonly known as the Cavalier d'Arpino. Agriculture, woolen manufacturing, and the quarrying of coloured marbles are the chief occupations. Pop. (1990 est.) mun., 7,978.

Arpino, Gerald, in full GERALD PETER ARPINO (b. Jan. 14, 1928, Staten Island, N.Y., U.S.). American ballet choreographer, a leader of the Joffrey Ballet from its founding in 1956.

While serving in the U.S. Coast Guard (1945–48), Arpino met dancer Robert Joffrey in Seattle, Wash., and learned dancing in his spare time. Later, after training and performing in New York City, he toured with the Ballet Russe and appeared in Broadway musicals. He helped Joffrey to found the Joffrey Ballet in 1956, and in 1961 he offered his first choreography, *Partita for 4* and *Ropes*. Over the years he became known for his hard, fast, youthful ballets. He became associate director of the company and then its artistic director after the death of Joffrey in 1988. He continued to hold that position except for a period from May to November 1990 in a budgetary and factional dispute with the board of directors.

arquebus (weapon): see harquebus.

Arrabal, Fernando (b. Aug. 11, 1932, Melilla, Spanish Morocco), Spanish-born French absurdist playwright, novelist, and filmmaker. Arrabal's dramatic and fictional world is often violent, cruel, and pornographic.

Arrabal worked as a clerk in a paper company, then studied law at the University of Madrid. He turned to writing in the early 1950s, and in 1955 he went to study drama in Paris, where he remained. The first volume of his plays was published in 1958, and the 1959 production of *Pique-nique en campagne* (*Picnic on the Battlefield*), an antiwar satire that contrasts the horrors of war with a cheerful family outing, brought him to the attention of the French avant-garde. Arrabal's most important play of this early period is probably *Le Cimetière des voitures* (1st perf. 1966; *Automobile Graveyard*), a parody of the Christ story. The characters in his plays are frequently childlike but seldom innocent; they are prostitutes, murderers, and torturers.

After the mid-1960s, Arrabal's plays became increasingly formal and ritualistic, evolving into what Arrabal called Théâtre Panique ("Panic Theatre"). Among the plays of this highly productive period are *L'Architecte et l'empereur d'Assyrie* (1967; *The Architect and the Emperor of Assyria*), in which the two characters assume each other's personae, and *Et ils passèrent des menottes aux fleurs* (1969; *And They Put Handcuffs on the Flowers*), more overtly political than his previous plays; its theme of freedom from oppression was inspired by the author's imprisonment while on a journey to Spain in 1967.

Arrabal's first novel, *Baal Babylone* (1959; *Baal Babylon*), dealt with his nightmarish childhood in fascist Spain; in 1970 he adapted it into the screenplay *Viva la Muerte!* ("Long Live Death!") and directed its filming in Tunisia. An extremely prolific writer, he also, in addition to producing a dozen volumes of collected theatre pieces, wrote novels, film-

scripts, poetry, political and other nonfictional texts, and two books on chess.

Arrah (city, India): see Ara.

arraignment, in Anglo-American law, first encounter of an accused person with the court prior to trial, wherein he is brought to the bar and the charges against him are read. The accused usually enters a plea of guilt or innocence. If he chooses not to plead, a plea of not guilty will be entered for him. A guilty plea will usually result in the case's being handed over for judgment. Sometimes the court will permit a guilty plea to be withdrawn.

In civil-law countries arraignment does not exist, but accused parties must be brought before an investigating magistrate within a certain time, and the magistrate in turn must give his findings to the trial judge within a specified period. See also indictment.

Arraiolos rug, embroidered floor covering made at Arraiolos, north of Évora in Portu-

Arraiolos rug from Portugal, 17th century; in the Textile Museum, Washington, D.C.

Textile Museum Collection, Washington, D.C. photograph, Otto E. Nelson

gal. The technique is herringbone or cross-stitch on a linen cloth foundation. Early Arraiolos rugs utilized designs derived from the Persians, from whom the Portuguese learned the craft. Portuguese artisans soon replaced these Persian designs with Portuguese folk-art patterns in more limited colours, and most of the later rugs are much smaller and simpler. A fine collection of these rugs is displayed in the National Museum of Ancient Art in Lisbon. Arraiolos rugs are still being produced.

Arran, largest island in the district of Cunningham, Strathclyde region (until 1975 in the county of Bute), Scotland, on the Atlantic coast at the mouth of the Firth of Clyde. Arran is approximately 20 miles (32 km) long and has a mean breadth of 9 miles (14 km) and an area of about 165 square miles (425 square km).

Arran is called "Scotland in miniature" because of the beauty and variety of its scenery. The north of the island includes the most dra-

matic scenery, dominated by Goat Fell (2,868 ft [874 m]). The surrounding glens, notably Glen Rosa, Glen Sannox, and Glen Monamore, abound in hill and rock climbs and are well stocked with game, including grouse and red deer. In the south, the landscape is gentler and more pastoral and abounds in standing stones dating from approximately 2000 BC. Norse raiders inhabited Arran for a considerable period prior to the defeat of Haakon IV in 1263. The King's Caves, on the west coast, sheltered Robert I the Bruce in the early 14th century. In 1503 Arran was awarded by royal charter to Sir James Hamilton, whose castle dominates Brodick, the island's unofficial capital. Three miles south of Brodick in Lamlash Bay lies Holy Island, a cone of basaltic rock, 1,030 ft high, containing St. Molais' Cave, the cell of a hermit of the 6th century.

Because of its scenery and its accessibility to densely populated urban areas such as Glasgow, Arran has become an extremely popular holiday island and yet remains unspoiled. It is reached by steamer from Ardrossan, southwest of Glasgow. Pop. (1991) 4,474.

Arran, EARLS OF, titled Scottish nobility, grouped below chronologically and indicated by the symbol ●.

● **Arran, James Hamilton, 1st earl of** (b. 1475?—d. July 1529, Kinneil, West Lothian, Scot.), son of James, 1st Lord Hamilton, and of Mary, daughter of James II of Scotland; he was created earl of Arran in 1503 on the occasion of the marriage of James IV with Margaret Tudor.

He commanded a naval expedition against England in 1513 but failed lamentably and returned to find his rival, the Earl of Angus, supreme at court. He therefore allied with the Duke of Albany, regent for James V, and was himself from 1517 to 1520 one of six vice-regents. But in the feuds of these years he had no fixed allegiance. His most spectacular encounter was the fierce fight between the Hamiltons and the Douglasses in the streets of Edinburgh known as "Cleanse the Causeway" (1520). When James V freed himself from the power of Angus in 1528, Arran joined him at Stirling.

● **Arran, James Hamilton, 2nd earl of, DUC (duke) DE CHÂTELHERAULT** (b. c. 1517—d. Jan. 22, 1575, Hamilton, Lanarkshire, Scot.), earl of Arran who was heir presumptive to the throne after the accession of Mary Stuart in 1542 and was appointed her governor and tutor.

He negotiated for a marriage between Mary and Prince Edward (afterward Edward VI of England) but suddenly abandoned the project and joined the French party. He then agreed to the marriage of Mary with the dauphin of France, receiving the title of duc de Châtelherault at this time (1549); and he resigned office in 1554 in favour of the queen dowager, Mary of Lorraine. On the outbreak of the Scottish Reformation he joined the lords of the congregation (1559) and became the acknowledged leader of the Protestant party. He was exiled in 1565, but he returned to Scotland in 1569 to support the Queen's cause, not accepting the fact of Mary's abdication and the regency for her son James VI until 1573.

● **Arran, John Hamilton, earl of:** see Hamilton, John Hamilton, 1st marquess of.

● **Arran, James Hamilton, 3rd earl of** (b. 1537?—d. March 1609), earl of Arran who

was twice considered as a husband both for Mary Stuart and for Henry VIII's daughter Elizabeth (afterward Elizabeth I). During his childhood these projects arose from his father's ambitions; later, when he had returned from commanding the Scots guards in France (1554–59) and had joined the lords of the congregation, the Protestants proposed him as suitor first for the hand of Elizabeth, and then, after December 1560, for that of Mary. He showed signs of insanity in 1562, and the rest of his life was spent in confinement.

● **Arran, James Stewart, earl of** (d. 1595, near Symington, Lanarkshire, Scot.), cousin of the 3rd earl, whose honours he claimed and for a short time legally enjoyed, from 1581 to 1585.

Both Stewart and his rival, Esmé, duke of Lennox, were deprived of office when the Protestant lords seized power by the raid of Ruthven (1582); but a year later they in turn were overthrown and driven into exile by Stewart. His tyranny and insolence, however, alienated many and caused his rapid fall from power. He was accused by Elizabeth I of England of the murder of Lord Russell on the border in July 1585 and was imprisoned; the banished lords returned and Stewart, proclaimed a traitor, fled in November 1585. From that time his movements are uncertain. He was ordered to leave Scotland in 1586 but may not have done so, and he returned to Edinburgh in 1592 and managed to have himself reinstated at court. He was assassinated near Symington by Sir James Douglas, nephew of the regent Morton, whose imprisonment and execution in 1581 Stewart had precipitated.

arrangement, in music, traditionally, any adaptation of a composition to fit a medium other than that for which it was originally written, while at the same time retaining the general character of the original. The word was frequently used interchangeably with transcription, although the latter carried the connotation of elaboration of the original, as in the virtuosic piano transcriptions of J.S. Bach's organ works by Franz Liszt, the Italian composer-pianist Ferruccio Busoni, and others. In later times the definitions were almost reversed, with arrangement connoting musical liberty in elaboration or simplification. In popular music and jazz, the word is often used synonymously with "score."

Arrangements of vocal compositions were crucial to the early history of instrumental music. Thus, vocal polyphony of the late Middle Ages and the Renaissance, including motets, chansons, and parts of the mass, was intabulated (transcribed so as to suggest finger positions rather than pitches) for the use of keyboard and lute players, permitting them to perform singly music written for several singers.

During the Baroque period (c.1600–1750), interest in arrangement declined, perhaps because of the increased importance of instrumental music and the waning significance of vocal writing. Bach, who arranged many of Antonio Vivaldi's violin concerti for harpsichord and organ, was a notable exception.

During the 19th century, with its stress on the piano, arrangements again became popular. Liszt transcribed Schubert songs as well as scenes from Wagner's music dramas. Brahms wrote for orchestra an arrangement of his own *Variations on a Theme by Haydn*, originally for two pianos, and of Bach's "Chaconne" from the *Partita in D Minor* for violin, which he recast as a piano study for the left hand. In the 20th century, Arnold Schoenberg in turn made elaborate orchestral arrangements of music by Bach, Georg Matthias Monn, and Brahms that amount to actual recompositions, quite unlike the popular Bach arrangements by Stokowski, Respighi, and others, which enjoyed a considerable vogue during the pre-World War II era.

Piano arrangements of opera and ballet scores, in particular, have long proven their value in the preparation of performances. Performance editions of problematically notated early scores often carry all the earmarks of highly subjective arrangements.

Arras, town, capital of Pas-de-Calais *département*, Nord-Pas-de-Calais region, former capital of Artois, northern France, on the Scarpe River, southwest of Lille. Of Gallo-Roman origin, it was the chief town (Nemetacum or Nemetocenna) of the Atrebatas, one of the last Gallic peoples to surrender to Caesar. The woollen industry dates from the 4th century. The Middle Ages was a period of great material and cultural wealth, when Arras became the English word for tapestry hangings. The fortunes of the town followed those of troubled Artois, and it passed through many hands before being joined for the last time to France in 1659 by the Treaty of the Pyrenees. A peace treaty (1435) was signed there by Philip the Good of Burgundy and Charles VII of France. The Peace of Arras in 1482 fixed the northern frontiers of modern France. From 1479 to 1484 Louis XI, after razing the walls, ordered a mass deportation of citizens. Arras was the birthplace of Robespierre. The French Revolution and both world wars destroyed many of its ancient buildings. The town centres on two arcaded and gabled squares, the Grande and Petite. The reconstructed 16th-century Gothic Hôtel de Ville is on the Petite Place.

Tapestry making has long been extinct. Industry is diversified, the major employers representing the metallurgical, textile, and veg-

The Gothic Hôtel de Ville (town hall) and belfry, Arras, Fr.

etable oil industries; the civil service is a major employer. There is an agricultural market. Pop. (1999) city, 40,590; urban agglom. 83,322.

Arras, Gautier d': see Gautier d'Arras.

Arras lace, bobbin lace made at Arras, Fr., from the 17th century onward and similar to that of Lille. Although Arras was known for its gold lace, its popularity rested on its exceptionally pure-white lace, stronger than Lille but with similar floral patterns. Arras lace was worn at the coronation (1714) of George I of England. In the 19th century Arras produced a light variety of lace called mignonette. After 1830 the industry declined.

arrastra, crude drag-stone mill for pulverizing ores such as those containing silver or gold or their compounds. See patio process.

Arrau, Claudio (b. Feb. 6, 1903, Chillán, Chile—d. June 9, 1991, Mürzzuschlag, Austria), Chilean-born American pianist, regarded as one of the 20th century's most renowned performers.

After studying privately in Santiago for two years, Arrau went to Berlin, where he studied with Martin Krause, a pupil of Franz Liszt, from 1912 to 1918. His serious career began with a recital in Berlin in 1914, and during the next decade he toured extensively in Europe, South America, and the United States. Between 1924 and 1940 he taught at Julius Stern's Conservatory in Berlin, and in 1941 he moved permanently to the United States. He continued his frequent touring past his 80th birthday.

Arrau concentrated on the music of Liszt, Johannes Brahms, Frédéric Chopin, Robert Schumann, Claude Debussy, and, above all, Ludwig van Beethoven. Regarded as one of the least ostentatious of the virtuoso pianists, Arrau developed a classical approach that exhibited an extreme concentration on detail, without sacrificing feeling.

Arrecifos (Caroline Islands): see Babelthup.

arrest, placing of a person in custody or under restraint, usually for the purpose of compelling obedience to the law. If the arrest occurs in the course of criminal procedure, the purpose of the restraint is to hold the person for answer to a criminal charge or to prevent him from committing an offense. In civil proceedings, the purpose is to hold the person to a demand made against him.

In both common-law and civil-law jurisdictions, certain prerequisites must be met before there can be any interference with individual liberty. An arrest warrant may be issued by a court or judicial officer on a showing of probable cause that a criminal offense has been committed and that the person charged in the warrant is probably guilty. An arrest warrant may validly be served only by the person or class of persons to whom the warrant is addressed. In many states of the United States this can be a private citizen as well as a police officer.

More numerous and of greater practical importance are arrests without warrants. A police officer may arrest a person who is committing or attempting to commit a crime in the officer's presence. An officer may also arrest a person provided that the officer reasonably believes a crime to have been committed and the person arrested to be the guilty party. In the United States an indictment provides sufficient warrant for arrest of the accused, because the return of an indictment by a grand jury constitutes a finding of "probable cause." Arrests may also be made of persons on probation or parole who have violated the conditions of their release, even though such violations do not involve commission of criminal acts. In many cases of minor offenses, the accused is not arrested but is notified of pending criminal proceedings by a summons.

Unlawful or invalid arrests may have a variety of important legal consequences. For instance, it is generally recognized that a search of the person arrested and of the immediate premises is valid when "incident" to a lawful arrest. But if the arrest is unlawful, the search is also invalid, and can be barred from the criminal proceedings. In some situations illegal arrest practices may even render a confession of the defendant inadmissible at the trial. In the United States, Supreme Court decisions in *Escobedo v. Illinois* (1964) and *Miranda v. Arizona* (1966) called for the exclusion of many types of evidence if the arresting officers failed to advise the suspect of his constitutional right not to answer any questions and to have an attorney present during such questioning. (See *Miranda v. Arizona*.)

Arrest in civil cases is today regarded as a drastic remedy, and in most jurisdictions

it is available only in situations specified by statute, such as the arrest of a debtor who may otherwise abscond. Arrest may also be authorized in connection with other specialized civil proceedings. The most prevalent instances of such arrests are of persons whose extreme mental disorders constitute a recognizable danger to themselves or to others.

Arrest, Heinrich Louis d' (b. July 13, 1822, Berlin, Prussia [Germany]—d. June 14, 1875, Copenhagen, Den.), German astronomer who, while a student at the Berlin Observatory, hastened the discovery of Neptune by suggesting comparison of the sky, in the region indicated by Urbain Le Verrier's calculations, with a recently prepared star chart. The planet was found the same night.

In 1851, while associated with the Leipzig Observatory, d'Arrest discovered a periodic comet that was subsequently named for him. In that same year he published a book on the 13 asteroids known at that time and began his studies of the nebulae for which he received the Gold Medal of the Royal Astronomical Society in 1875.

Arrhenius, Svante (August) (b. Feb. 19, 1859, Vik, Swed.—d. Oct. 2, 1927, Stockholm), Swedish physical chemist best known for his theory that electrolytes, certain sub-

Arrhenius, 1918

By courtesy of the Kungl. Biblioteket, Stockholm

stances that dissolve in water to yield a solution that conducts electricity, are separated, or dissociated, into electrically charged particles, or ions, even when there is no current flowing through the solution. In 1903 he was awarded the Nobel Prize for Chemistry.

Early training. Arrhenius is said to have taught himself to read at the age of three and to have become interested in mathematics from watching his father add columns of figures. He attended the Cathedral School at Uppsala and went on to the university, where he studied physics, mathematics, and chemistry. In pursuit of his doctorate he migrated to Stockholm to work on electrolysis under Erik Edlund. In 1883 he published his first paper and in May 1884, at Uppsala, defended his doctoral thesis containing in embryo the dissociation theory.

The thesis was greeted with incredulity and awarded the fourth class, a bare pass; the university in effect condemned an important and original thesis. The faculty at Uppsala were skeptical of hypotheses and devoted to accurate experimental work, while Arrhenius boasted (not quite truly) that he had never performed an exact experiment in his life; moreover, his subject fell awkwardly between chemistry and physics. Even to the sympathetic English physicist Sir Oliver Lodge, who in 1886 described the theory to the British Association for the Advancement of Science, Arrhenius seemed sometimes "to indulge in . . . manipulation of imaginary data," producing "a confusion" from which emerged so-called theoretical deductions. In reality, Arrhenius had a statistical sense and an ability to frame formulas to fit his facts, both of which were rare among chemists of his day. He had pru-

dently sent copies of his thesis to the most prominent physical chemists of the day, who were able to understand it; and in August 1884 the German physical chemist Wilhelm Ostwald went from Riga to Uppsala to offer Arrhenius a post. He was at once given a lectureship in physical chemistry at Uppsala; and in 1886 Edlund got him a traveling fellowship from the Swedish Academy of Sciences.

Acceptance of his theory. Arrhenius spent the period from 1886 to 1890 working with other eminent scientists—Ostwald at Riga, F.W. Kohlrausch at Würzburg, Ludwig Boltzmann at Graz, and Jacobus van't Hoff at Amsterdam. During these years he refined his theory, which gradually began to win adherents. In 1891 he was offered a chair at Giessen, Ger., where Justus von Liebig, half a century earlier, had revolutionized the teaching of chemistry; but he wished to remain in Sweden and obtained a post at the Royal Institute of Technology in Stockholm. In 1895 he became professor of physics and, in 1896, rector of the school. Abroad, his reputation stood very high; but he was not elected to the Swedish Academy of Sciences until 1901, and even then with strong opposition. In 1902 he received the Davy Medal of the Royal Society of London, which in 1911 elected him a foreign member; and in 1903 his own countrymen made amends when he became the first Swede to be awarded a Nobel Prize.

In 1905 he was offered a chair at the University of Berlin, then the most eminent position open to an academic chemist. On patriotic grounds, he refused; and the directorship of the Nobel Institute for Physical Chemistry at Stockholm was created for him. This gave him ample opportunity for research and writing, and his later years were contented.

In 1911 he visited the United States to receive the first Willard Gibbs Medal and to deliver the Silliman Lectures at Yale University, with the latter published as *Theories of Solutions* (1912).

Arrhenius was a genial, energetic man who made many friends on his visits abroad. His memory was excellent, he loved nature, but he was indifferent to the fine arts and literature. His range of scientific interests was very wide: over the years, he moved away from the study of solutions into immunology, where he made pioneering studies on toxins, and then into geology and cosmology. In *Worlds in the Making* (1908), he suggested that cool stars might collide and form nebulae from which new stars and planets would arise; and so the process would go on indefinitely, life being spread about the universe by bacteria propelled by light pressure. These speculations have not found their way into modern cosmology. (D.M.K.)

Arrhenius equation, mathematical expression that describes the effect of temperature on the velocity of a chemical reaction, the basis of all predictive expressions used for calculating reaction-rate constants. In the Arrhenius equation, k is the reaction-rate constant, A and E are numerical constants characteristic of the reacting substances, R is the thermodynamic gas constant, and T is the absolute temperature. The equation is commonly given in the form of an exponential function,

$$k = A \exp(-E/RT),$$

and it predicts that a small increase in reaction temperature will produce a marked increase in the magnitude of the reaction-rate constant.

The Arrhenius equation was originally formulated by J.J. Hood on the basis of studies of the variation of rate constants of some reactions with temperature. The Swedish chemist Svante Arrhenius, for whom the equation is named, showed that the relationship is appli-

cable to almost all kinds of reactions. He also provided a theoretical basis for the equation by an analogy with the expression for the thermodynamic equilibrium constant. Later, the numerical constants A and E were shown by the collision and transition-state theories of chemical reactions to represent quantities indicative of the fundamental process of chemical reactions; *i.e.*, E represents the energy of activation, and A represents the frequency at which atoms and molecules collide in a way that leads to reaction.

Arrhenius theory, theory, introduced in 1887 by the Swedish scientist Svante August Arrhenius, that acids are substances that dissociate in water to yield electrically charged atoms or molecules, called ions, one of which is a hydrogen ion (H^+), and that bases ionize in water to yield hydroxide ions (OH^-). It is now known that the hydrogen ion cannot exist alone in water solution; rather, it exists in a combined state with a water molecule, as the hydronium ion (H_3O^+). In practice the hydronium ion is still customarily referred to as the hydrogen ion.

The acidic behaviour of many well-known acids (*e.g.*, sulfuric, hydrochloric, nitric, and acetic acids) and the basic properties of well-known hydroxides (*e.g.*, sodium, potassium, and calcium hydroxides) are explained in terms of their ability to yield hydrogen and hydroxide ions, respectively, in solution. Furthermore, such acids and bases may be classified as strong or weak acids and bases depending on the hydrogen ion or hydroxide ion concentration produced in solution. The reaction between an acid and a base leads to the formation of a salt and water; the latter is the result of the combination of a hydrogen ion and a hydroxide ion.

arrhythmia, cardiac: *see* cardiac arrhythmia.

Arriaga (y Balzola), Juan Crisóstomo (Jacobo Antonio) (b. Jan. 27, 1806, near Bilbao, Spain—d. Jan. 17, 1826, Paris, Fr.), Spanish composer of extraordinary precocity whose potential was cut short by his early death. Stylistically, his music stands between the Classical tradition of Joseph Haydn and Wolfgang Amadeus Mozart and the Romanticism of Gioacchino Rossini and Franz Schubert; it shows abundant invention, freshness, and technical resourcefulness.

After the success of his opera *Los esclavos felices* (produced 1820, Bilbao) and of an octet for French horn, strings, guitar, and piano, Arriaga enrolled in the Paris Conservatory, where by the age of 18 he became an assistant professor. His other compositions include three string quartets and a symphony.

Arrian, Latin in full FLAVIUS ARRIANUS (b. Nicomedia, Bithynia [now İzmit, Tur.]—d. c. AD 180), Greek historian and philosopher who was the author of a work describing the campaigns of Alexander the Great. Entitled *Anabasis*, presumably in order to recall Xenophon's work of that title, it describes Alexander's military exploits in seven books; an eighth, the *Indica*, tells of Indian customs and the voyage of Nearchus in the Persian Gulf.

Arrian was clearly a great admirer of his hero but was obsessed by the purely military aspect of the story he was telling. There is little to enlighten us about Alexander's motives for conquest or his ideal of the creation of a united world. The work, however, does contain some fine pieces of descriptive writing, such as the account of the siege and capture of Tyre in Book Two.

Arrian's other works include the *Encheiridion*, a manual of the teachings of Epictetus, the Stoic philosopher whose disciple Arrian

was. This work was much used in the European Middle Ages as a guide to the principles of the monastic life.

Arrian served in the Roman army and was appointed by the emperor Hadrian to be governor of the province of Cappadocia. After Hadrian's death (138), Arrian retired into private life to occupy himself with his literary work.

Arron, Henck (Alphonsus Eugène) (b. April 25, 1936, Paramaribo, Dutch Guiana [now Suriname]), politician who became prime minister of Suriname in 1973 and led that nation to independence in 1975. He was overthrown by a military coup in 1980.

Arron worked in banks in The Netherlands and Dutch Guiana before entering politics in 1963. He was elected to the Staten (Suriname legislature) that year as a member of the Suriname National Party, and he became the party's leader in 1970. Arron formed the National Party Alliance, a coalition of parties that were composed mainly of Creoles (Surinamese of African descent) and that favoured independence from The Netherlands. Arron's coalition won the elections of 1973, and he became prime minister. He led his nation to independence in 1975 after two years of negotiations with The Netherlands. Arron was reelected in 1977, but his efforts to stem Suriname's calamitous economic decline following independence were unsuccessful, and a high rate of unemployment was a major cause of his downfall. A coup was staged by discontented junior army officers in February 1980. Arron was arrested and was released in 1981, after which he returned to his banking activities.

arrow (weapon): *see* bow and arrow.

Arrow, Kenneth J(oseph) (b. Aug. 23, 1921, New York, N.Y., U.S.), American economist known for his contributions to welfare economics and to general economic equilibrium theory. He was cowinner (with Sir John R. Hicks) of the Nobel Prize for Economics in 1972. Perhaps his most startling thesis (using elementary mathematics) was the "impossibility theorem" (or "Arrow's theorem"), which holds that, under certain conditions of rationality and equality, it is impossible to guarantee that a ranking of societal preferences will correspond to rankings of individual preferences when more than two individuals and alternative choices are involved.

Arrow received his Ph.D. from Columbia University in 1951 and taught at the University of Chicago (1948–49) and Stanford University (1949–68). From 1968 to 1979 he was professor of economics at Harvard University, where he inspired the development of a first-rate school of economic theorists. In 1979 he returned to Stanford University.

Among his major publications are *Social Choice and Individual Values* (1951), *Essays in the Theory of Risk Bearing* (1971), and *The Limits of Organization* (1974).

Arrow Cross Party, Hungarian NYILASKERESZTES PÁRT, Hungarian fascist organization that controlled the Hungarian government from October 1944 to April 1945 during World War II. It originated as the Party of National Will founded by Ferenc Szálasi in 1935. Szálasi's party was quite small and underwent numerous reorganizations; it reconstituted itself under a new name and emerged early in 1939 as the Arrow Cross Party. In the May 1939 national elections it became the second most popular party, receiving about 30 seats in parliament.

After World War II broke out, however, the Hungarian prime minister Pál Teleki (served February 1939–April 1941) suppressed the Arrow Cross Party, imprisoning many of its adherents. When the Germans occupied Hungary and set up the collaborationist government of Döme Sztójay (March 1944), how-

ever, the Arrow Cross fortunes improved; the party received official approval from the new government and gained considerable popular support.

When the regent of Hungary, Admiral Miklós Horthy, began to seek a separate peace with the Allies (September 1944), the Germans decided to place Szálasi in power as prime minister (October 27), then as national leader (November 4). After the Soviet Union's Red Army seized Budapest in February 1945, it drove the Germans and their Arrow Cross allies out of Hungary.

arrow-poison frog, any of the closely related, poisonous frogs of the genera *Dendrobates* and

Arrow-poison frog (*Dendrobates*)

Joseph T. Collins, Museum of Natural History, University of Kansas

Phylllobates (family Dendrobatidae). These two genera include small, brightly coloured, terrestrial frogs of South and Central American forests. Their skins secrete a substance that is toxic to birds and small animals and is used by Indians to coat their arrow tips. The vivid colours of arrow-poison frogs include red, orange, yellow, green, and pink.

Breeding behaviour in the two genera is similar. The fertilized eggs are attached to the back of the male, and, after hatching, the tadpoles cling to his back. The male later carries the young to a stream, where they detach and complete their development into adults.

arrowhead, any freshwater plant of the genus *Sagittaria*, consisting of about 20 species distributed worldwide, having leaves resembling arrowheads. Arrowhead is a perennial herb with fleshy, or tuberous, roots that grows in shallow lakes, ponds, and streams. The flowers have three rounded petals. The tubers of

Arrowhead (*Sagittaria*)

Kenneth and Brenda Formanek—EB Inc

some North American species were eaten by Indians and were known to early settlers as duck, or swan, potatoes. The most common species in North America is the broad-leaved arrowhead (*S. latifolia*), introduced by man to improve feeding areas for birds. Leaves of this species vary from arrow-shaped to grasslike. The grass-leaved arrowhead (*S. graminea*) is found throughout eastern North America. *S. sagittifolia*, which grows in most of Europe, is cultivated in China for its edible tubers.

arrowroot, any of several species of the genus *Maranta*, members of the family Marantaceae (*q.v.*), the rhizomes, or rootstocks, of which yield an edible starch; the chief among these is *M. arundinacea*, the source of genuine, or West Indies, arrowroot. This herbaceous perennial, probably a native of Guyana and western Brazil, is cultivated throughout the West Indies, Southeast Asia, Australia, and South Africa. Its creeping rootstock has fleshy tubers (underground storage organs), and its many-branched stem, reaching a height of 5–6 feet (about 1.5 metres), bears numerous leaves, having long narrow sheaths and large spreading ovate blades, and a few short-stalked white flowers. Plants are harvested when the tubers are gorged with starch, just before the plant's dormant season. The roots are peeled and then grated in water. The resulting mixture is dried to a powder and purified by several washings.

Arrowroot, almost pure starch, supplies no vitamins and contains only 0.2 percent protein. In cookery, it is used as a thickener in soups, sauces, puddings, and desserts. When boiled in water, it yields a transparent, odourless, pleasant-tasting jelly. Its fine texture allows cooking at lower temperatures and for shorter periods than other starches, making it especially suitable for such egg preparations as custards, which are adversely affected by overcooking. Arrowroot is easily digested and is used in diets requiring bland, low-salt, and low-protein foods.

The name arrowroot is sometimes applied to starches obtained from other plants and used as substitutes for true arrowroot. Tous-les-mois, or Tulema arrowroot, a larger grained product, comes from another West Indies plant, a species of *Canna*, a genus allied to the *Maranta*. East India arrowroot is a product of several species of the genus *Curcuma*, of the

Arrowroot (*Maranta arundinacea*)
W.H. Hodge

family Zingiberaceae, chiefly *C. angustifolia*, native to central India. Brazilian arrowroot, from the cassava plant (*Manihot esculenta*), is the source of tapioca. Tacca, or Otaheite arrowroot, comes from the pia plant (*Tacca pinnatifida*) of the South Pacific islands. Portland arrowroot, once manufactured in Portland, Dorset, Eng., is derived from tubers of the common cuckoopint (*Arum maculatum*), and other *Arum* species are important food starch sources in hot countries. Potato farina, sometimes marketed as British arrowroot, has been used to adulterate more costly preparations.

Arrowsmith, Aaron (b. July 14, 1750, Winstan, Durham, Eng.—d. April 23, 1823, Lon-

don), British geographer and cartographer who engraved and published many fine maps and

Aaron Arrowsmith, engraving by T.A. Dean after a portrait by H.W. Pickersgill

By courtesy of the trustees of the British Museum, photograph J.R. Freeman & Co Ltd

atlases based on the best available sources of the day.

Without a formal education Arrowsmith went to London c. 1770 and, after working as a surveyor, established himself as a mapmaker and publisher. His large world map (1790) established his reputation. A second such map published in 1794 was accompanied by an explanatory volume. Other notable works included a map of North America (1796), a chart of the Pacific Ocean (1798), and his *Atlas of South India* (1822).

After Arrowsmith's death, the business was carried on by his sons, Aaron and Samuel, who published geography manuals and a number of atlases. From 1839 the business was conducted by his nephew, John Arrowsmith, himself an eminent cartographer, who published the *London Atlas* 4 vol. (1834), the best set of maps then in existence. This work was followed by a long series of elaborate and carefully executed maps embodying the results of contemporary exploration. The maps of Australia, North America, Africa, and India were especially valuable.

arrowworm, also called CHAETOGNATH, any member of the invertebrate phylum Chaetognatha, a group of small wormlike marine animals with transparent to translucent or opaque arrow-shaped bodies. The phylum consists of about seven extant genera and one fossil genus. There are more than 50 species, most of which are in the genus *Sagitta*. The size of arrowworms ranges from about 3 millimetres to more than 100 millimetres; species inhabiting colder waters generally are larger than those from tropical seas. Chaetognatha are hermaphroditic (having both male and female sex organs, or gonads). The body is divided into head, trunk, and tail by two transverse walls or membranes and has lateral fins and a tail fin. Respiratory, circulatory, and excretory systems are not properly developed.

Natural history. Arrowworms are protandric (*i.e.*, male gonads mature earlier than female gonads). Most arrowworms die after spawning, although some undergo cycles of maturity and often also growth. Cross-fertilization has been observed, the sperm passing from the storage organs called seminal vesicles, which open out to the exterior, to the seminal receptacle (tube along the female gonads) of another individual. The eggs are fer-

tilized by the sperm either shortly before or as they are laid, in a part of the duct common to the oviduct and to the seminal receptacle. In several genera (*e.g.*, *Eukrohnia*, and probably also in the genera *Bathyspadella*, *Krohnitta*, and *Heterokrohnia*), mature eggs and larvae are enclosed in a sac formed at the opening of oviducts. In *Pterosagitta*, eggs are laid in a capsule; in *Sagitta*, eggs are discharged into the surrounding water one at a time in several cycles; and in *Spadella*, eggs have an adhesive coat and a stalk and attach to any surface.

Arrowworms are voracious feeders; they consume copepods, euphausiids, fish larvae, medusae, other arrowworms, cladocerans, amphipods, appendicularians, and eggs and larvae of various animals. Arrowworms inhabit oceans, seas, and coastal lagoons. Although some species are cosmopolitan, others are restricted to a geographical region or an ocean. Southeast Asian seas have the largest number of species. Epiplanktonic species—*i.e.*, those within 200 metres of the water surface—increase in numbers from the poles to the

Arrowworm (*Sagitta*)

Douglas P. Wilson

Equator. Mature arrowworms inhabit deeper oceanic layers than do the young.

Form and function. The body of an arrowworm is covered by a cuticle of cells (called collarete when thickened). The head has hooks (curved, grasping spines) covered by a hood or thin fold of skin, which retracts when the arrowworm is catching prey. Head muscles control the movement of hooks, teeth, and mouth; body muscles are longitudinal with some transverse bands. Arrowworms swim with dartlike movements by contracting the longitudinal muscles and flapping the tail.

The nervous system consists of a large cerebral ganglion with sensory nerves (*e.g.*, optic, coronal). The cerebral ganglion is connected with the ventral ganglion by a pair of nerve cords. Additional ganglia and nerves spread along the body. Touch receptors, small, round, ciliated (hairlike) prominences, are scattered over the body.

There is evidence that regeneration of the head and the anterior part of the body occurs: during regeneration, the eyes appear first, then the mouth and hooks. The eyes contain a pigmented central cell, which encloses five clusters of photoreceptor cell processes (or ocelli). A conical body found in the photoreceptor cell either may guide the animal as it swims or act as a resonator. The pigmented central cell may have various shapes (*e.g.*, starlike) in different species. No pigment is present in most deep-sea dwelling species.

Body plan of arrowworm (*Sagitta bipunctata*)

The corona ciliata is an olfactory (smell) receptor or chemoreceptor peculiar to the phylum and is formed by a series of rows of ciliated cells forming a ring or elongated oval at the neck or extending toward the head and the trunk. The digestive tract, which is lined by glandular and absorptive cells, extends from the mouth to the anus and is supported by a mesentery. The central mesentery divides the trunk and tail into two cavities. Trunk and tail regions are filled with a colourless fluid that circulates forward along the body walls and backward in the medial region of the body.

Two ovaries, filled with rows of unfertilized eggs, extend along the trunk and are attached to the sides of the body by a mesentery. The seminal receptacle in the oviducts stores sperm after copulation. The testes are located in the tail cavities; a spermduct, or vas deferens, connects the testes with the seminal vesicles, which open out from the body. The ovaries in the trunk, therefore, are isolated from the testes in the tail, with no internal communication between male and female gonads. The seminal vesicles burst when filled with sperm, ejecting the spermatozoa into the surrounding waters or into the seminal receptacle of another individual.

Classification. The Chaetognatha is an isolated phylum in the animal kingdom; *i.e.*, comparative anatomy and embryology fail to link these animals with any other group. Arrowworms have been considered as worms, and attempts have been made to relate them to many animal groups (*e.g.*, Heteropoda, Annelida, Nematoda, Arthropoda). They also have been placed taxonomically between Annelida and Nematoda. Structure of the arrowworm eye, however, indicates a probable evolutionary relationship to echinoderms and chordates.

arroyo, also called WADI, WASH, DRY WASH, or COULEE, Arabic WĀDĪ, French OUED, a dry

Ephemeral stream (arroyo) in Big Bend National Park, Texas

Grant Heilman

channel lying in a semiarid or desert area and subject to flash flooding during seasonal or irregular rainstorms. Such transitory streams, rivers, or creeks are noted for their gully-ing effects, especially for their rapid rates of erosion, transportation, and deposition. There have been reports of up to 8 feet (2 m) of deposition in 60 years and like amounts of erosion during a single flood event.

The beds of ephemeral streams are commonly almost flat in cross section and are dry most of the time. Such beds are given various names according to regional differences, such as wadi or oued in North Africa and Saudi Arabia and dry wash or arroyo in the southwestern United States. Most ephemeral streams become shallower downstream, and most of the water is absorbed by the dry stream bed; mudflows are a fairly common

occurrence because sediment yields are high in arid and semiarid areas.

Arrupe, Pedro (b. Nov. 14, 1907, Bilbao, Spain—d. Feb. 5, 1991, Rome, Italy), 28th superior general (1965–83) of the Society of Jesus.

Arrupe studied medicine at the University of Madrid, but, after witnessing the poverty in that city, he left school to join the Jesuits in 1927. When the Spanish government dissolved the Jesuit order in Spain in 1932, Arrupe continued his religious studies elsewhere in Europe and in the United States, where he was ordained at St. Mary's Seminary in Kansas in 1936. In 1938 he went to Japan, where he took his final vows as a Jesuit in 1943 and spent a total of 27 years as a missionary. In 1945 he headed the first rescue party to go into Hiroshima after that city had been devastated by the atomic bomb. He subsequently became Jesuit vice provincial (1954–58) and then the first Jesuit provincial for Japan (1958–65).

Arrupe was elected superior general of the Jesuits in 1965. He led the Society of Jesus during an upsurge of liberalism among some of its members, who supported such ideas as a married priesthood and social and political work among the poor in developing countries (*i.e.*, liberation theology). In the 1970s these activities brought the Jesuits into conflict with the papacy, which regarded the moderately liberal Arrupe as being overly permissive in his administration of the order. Arrupe resigned in 1983 owing to ill health and was in fact the first Jesuit superior general to resign instead of remaining in office until his death.

Ars, Jean-Baptiste-Marie Vianney, cure d': *see* Vianney, Saint Jean-Baptiste-Marie.

Ars Antiqua (Medieval Latin: "Ancient Art"), in music history, period of musical activity in 13th-century France, characterized by increasingly sophisticated counterpoint (the art of combining simultaneous voice parts), that culminated in the innovations of the 14th-century Ars Nova (*q.v.*). The term Ars Antiqua originated, in fact, with the Ars Nova theorists, some of whom spoke of the "Ancient Art" with praise, others with contempt. All of them, however, agreed upon a marked difference between the two styles, a difference rooted primarily in the profound rhythmic innovations of the Ars Nova. Those theorists limited the Ars Antiqua to the latter part of the 13th century, while modern music historians have broadened the term to encompass the entire century.

The authorship of most of the music of the Ars Antiqua is anonymous. Nevertheless, three important figures emerge from the general obscurity: Pérotin (flourished late 12th century), who succeeded the famed Léonin at the Cathedral of Notre-Dame in Paris and who composed the earliest known music for four voices; Franco of Cologne (flourished mid-13th century), a theorist, whose *Ars cantus mensurabilis* ("The Art of Measured Song") served to organize and codify the newly formed mensural system (a more precise system of rhythmic notation, the direct ancestor of modern notation); and Pierre de la Croix (flourished last half of 13th century), whose works anticipate the Ars Nova style by virtue of their rhythmic fluency.

The most important form to originate in the Ars Antiqua is the motet, which retained its popularity for centuries. The essence of this form is its simultaneous presentation of more than one text. It seems to have begun with the addition of a new text to the upper voice(s) of a sacred polyphonic composition, the slower moving lower voice retaining its original sacred text. The next text—in Latin, like the original text—at first complemented or amplified the meaning of the original words. Later, the language of the added text changed

to French while the sentiments became more worldly, resulting in compositions in which the sacred Latin text of the lower voice is accompanied by one or more secular French texts in the upper voice(s).

Ars Nova (Medieval Latin: "New Art"), in music history, period of the tremendous flowering of music in the 14th century, particularly in France. The designation Ars Nova, as opposed to the Ars Antiqua (*q.v.*) of 13th-century France, was the title of a treatise written about 1320 by the composer Philippe de Vitry. Philippe, the most enthusiastic proponent of the "New Art," demonstrates in his treatise the innovations in rhythmic notation characteristic of the new music.

These innovations, which were anticipated to a degree in the music of Pierre de la Croix (flourished last half of 13th century), are marked by the emancipation of music from the rhythmic modes (dominated by triple metre) of the preceding age and by the increased use of smaller note values. An important opponent of Philippe de Vitry's progressive ideas was the theorist Jacques de Liège, whose *Speculum musicae* ("The Mirror of Music") extolls the virtues of the older masters of the Ars Antiqua.

Some of the earliest examples of works in the new style may be found in the *Roman de Fauvel* (*c.* 1315), a narrative manuscript that contains compositions from both the Ars Nova and the Ars Antiqua. The most important composers of the Ars Nova are Philippe de Vitry and the composer and poet Guillaume de Machaut, whose work forms a substantial proportion of the surviving repertory. The production of polyphonic secular music, represented by the ballade, virelai, and rondeau (*qq.v.*), increased decidedly in the 14th century.

The term Ars Nova, specifically applicable to the French music of the 14th century, has been used less discriminately by a number of writers who refer to "Italian Ars Nova," which is also known as Italian trecento music. The most important theorist of this school was Marchettus of Padua, whose treatise *Pomerium* (in the early 14th century) outlines certain rhythmic innovations in Italian notation of the time. The most important composers of 14th-century Italy are Jacopo da Bologna, Francesco Landini, and Ghirardello da Firenze.

Arsaces, Iranian name borne by the Parthian royal house as being descended from Arsaces, son of Phriapites (date unknown), a chief of the seminomadic Parni tribe from the Caspian steppes. The first of his line to gain power in Parthia was Arsaces I, who reigned from about 250 to about 211 bc. (Some authorities believe that a brother, Tiridates I, succeeded Arsaces about 248 and ruled until 211; other authorities consider Arsaces I and Tiridates I to be the same person.)

All Parthian kings after Arsaces I used Arsaces as their throne name; and, with the rare exceptions of usurpers and contestants for the throne, all are so designated on their coins and in official documents. By historians they are generally called by their personal names. The Arsacid dynasty maintained itself, although not in unbroken succession, until its overthrow by Ardashir in ad 224. During the time of the Parthian empire the Arsacids claimed descent from Artaxerxes II, probably to legitimate their rule over Achaemenid territories. From the Sāsānian chronicles they enter Persian epic poetry under the name Ashkanian (individual rulers as Ashak, Ashkan).

The name Arsaces was also borne by several kings of Armenia who were of Parthian royal blood.

Arsaces II (king): *see* Artabanus I.

Arsaces VI: *see* Mithradates I under Mithradates (Parthia).

Arsacid DYNASTY, also called ARSHAKUNI (247 BC–AD 224), ancient Iranian dynasty that founded and ruled the Parthian empire. The progenitors of the dynasty were members of the Parni tribe living east of the Caspian Sea. They entered Parthia (*q.v.*) shortly after the death of Alexander the Great (323 BC) and gradually gained control over much of Iran and Mesopotamia until, in AD 224, they were overthrown by the Sāsānians, an Iranian dynasty founded by Ardashīr I.

The first Arsacid to gain power in Parthia was Arsaces (reigned c. 250–c. 211 BC), but the Iranian plateau was not conquered in its entirety until the time of Mithradates I (reigned 171–138 BC). Two of the dynasty's most powerful rulers were Mithradates II (reigned 123–88 BC) and Phraates III (reigned 70–58/57 BC).

During the time of the Parthian empire the Arsacids claimed descent from the Achaemenian king Artaxerxes II, probably to legitimize their rule over the former Achaemenian territories; in fact, in many of its outward forms the Parthian empire was a revival of Achaemenian rule. The empire's governmental organization, however, was based on that developed by the Hellenistic Seleucids. The Arsacids encouraged the development of Hellenistic cities and tolerated the formation of vassal kingdoms. Because the Arsacids and their vassals controlled almost all the trade routes between Asia and the Greco-Roman world, they became very wealthy, with the result that the Parthian period was one of intense building activity.

arsenate mineral, any of a group of naturally occurring compounds of arsenic, oxygen, and various metals, most of which are rare, having crystallized under very restricted conditions. At the mineralogically famous Långban iron and manganese mines in central Sweden, more than 50 species of arsenate minerals have been described, many peculiar to the locality. Such compounds occur in open cav-

ities and resulted from the reaction of arsenic acid (H_3AsO_4) upon pyrochroite [manganese hydroxide; $Mn(OH)_2$] at moderate to low temperature. Arsenates at other localities are often oxidation products of arsenide ores and are deposited at low temperatures in late-stage veins and open cavities.

Only a few arsenate minerals have economic importance. Because the transition metals (*e.g.*, cobalt, copper, nickel) give brilliant colour to some of the arsenates, these can be used to advantage in prospecting; such arsenate oxidation products, or blooms, as erythrite (bright pink) and annabergite (green) are indicators of nickel and cobalt arsenide ores. Many of the nickel and cobalt deposits at Sudbury and Cobalt, Ont., were located in this manner.

The arsenate minerals, which are salts of arsenic acid, contain arsenate groups (AsO_4) in which four oxygen (O) atoms are arranged at the corners of a tetrahedron about a central arsenic (As) atom. Each arsenate tetrahedron has a net electric charge of -3 , which is neutralized by large, positively charged metal ions (*e.g.*, calcium, manganese, or ferrous iron) outside the tetrahedron. Unlike the similar silicate tetrahedra, which link to form chains, sheets, rings, or frameworks, arsenate tetrahedra are insular.

The crystal structure of the arsenate minerals is very similar to that of the phosphate and vanadate minerals; indeed, many arsenate minerals form solid solutions with both the phosphates and the vanadates.

arsenic (As), a chemical element in the nitrogen family (Group Va of the periodic table), existing in both gray and yellow crystalline forms. Although compounds of arsenic were known as early as the 4th century BC, the element was not identified as such until 1649.

A brief treatment of arsenic follows. For full treatment, see MACROPAEDIA: Chemical Elements: *Nitrogen group elements*.

Occurrence, properties, and uses. Arsenic is widely distributed in nature, and this element occasionally is found uncombined, generally in association with such metals as antimony

Arsenic (gray) with realgar (red) and orpiment (yellow)
By courtesy of the Joseph and Helen Guetterman collection, photograph, John H. Gerard

and silver. Arsenic also occurs combined in its sulfides realgar and orpiment, as arsenic oxide, and as a constituent of various metallic sulfides, of which arsenopyrite (*q.v.*) is the most abundant.

Although some forms of arsenic are metallic, the element is best classified as a non-metal. Gray, or metallic, arsenic, which is more stable and more common than the softer yellow form, is very brittle, tarnishes in air, and sublimes when heated strongly—*i.e.*, it passes directly into a vapour without melting and reverts to the crystalline solid without liq-

Arsenate minerals

name formula	colour	lustre	Mohs hardness	specific gravity	habit	fracture or cleavage	refractive indices	crystal system space group	remarks
erythrite $Co_3(AsO_4)_2 \cdot 8H_2O$	crimson or peach-red (erythrite); lightening to white, gray, and pale or apple-green (annaberg- ite)	weakly adamant- ine; sometimes dull or earthy	$1\frac{1}{2}$ – $2\frac{1}{2}$	3.0	radiating crystal groups; glob- ular or reni- form concre- tions; earthy or powdery masses	one perfect cleavage	anna eryth $\alpha = 1.622$ – 1.629 $\beta = 1.658$ – 1.663 $\gamma = 1.687$ – 1.701	monoclinic $C\frac{2}{m}$	forms a solid solu- tion series with annabergite in which nickel re- places cobalt in the molecular structure
mimetite $Pb_3(AsO_4)_3Cl$	olive-green; gray; yellow; brown to orange	resinous to subad- amantine	$3\frac{1}{2}$ –4	7.0	barrel-shaped prisms; globular, reniform, or botryoidal masses	uneven to subcon- choidal fracture	$\omega = 2.041$ – 2.144 $\epsilon = 2.030$ – 2.131	hexagonal $C\frac{6_3}{m}$	forms solid solu- tion series with pyromorphite in which phosphorus replaces arsenic, with vanadinite in which vanadium replaces arsenic, and with hedy- phane in which calcium replaces lead in the molecular structure
pharmacosiderite $Fe_3(AsO_4)_2(OH)_3 \cdot 5H_2O$	olive-green to honey- yellow to brown	adamantine	$2\frac{1}{2}$	2.8	transparent to translucent, stated cubes	one im- perfect to good cleavage	$n = 1.676$ – 1.704	isometric $P\bar{4}3m$	weakly piezoelectnc and pyroelectric
scorodite $FeAsO_4 \cdot 2H_2O$	various greens to grayish or liver-brown (scorodite); white to pale gray (mansfield- ite)	strongly vitreous to subad- amantine and sub- resinous	$3\frac{1}{2}$ –4	3.0–3.3	irregular crystal ag- gregates or earthy masses (scorodite); crusts and porous masses (mansfieldite)	subcon- choidal fracture	mans scor $\alpha = 1.622$ – 1.784 $\beta = 1.624$ – 1.795 $\gamma = 1.642$ – 1.814	orthorhombic $Pcab$	forms solid solu- tion series with mansfieldite in which aluminum replaces iron in the molecular structure
svabite $Ca_5(AsO_4)_3F$	colourless; yellowish white to gray; gray- ish green	vitreous to sub- resinous	4–5	3.5–3.8	brittle, transparent or trans- lucent, short prisms	indistinct cleavage	$\omega = 1.703$ – 1.709 $\epsilon = 1.695$ – 1.701	hexagonal	forms a solid solu- tion series toward fluorapatite with phosphorus partially replacing arsenic in the molecular structure

uefying upon cooling the vapour. In addition to gray and yellow arsenic, other forms (allotropes) have been reported.

Elemental arsenic has few practical uses, one of which is to impart more nearly spherical shape in the manufacture of lead shot. It is also used in certain alloys to increase strength at elevated temperatures, in bronzing, and in pyrotechnics. All naturally occurring arsenic consists of the stable isotope arsenic-75; the radioactive isotopes arsenic-72, -74, and -76 have been used in medical diagnostic procedures.

Principal compounds. Because arsenic has a range of oxidation states from -3 to +5, it can form a variety of different kinds of compounds. Among the most important commercial compounds are the oxides, the principal forms of which are arsenious oxide (As_2O_3) and arsenic pentoxide (As_2O_5). Arsenious oxide, commonly known as white arsenic, is obtained as a by-product from the roasting of the ores of copper, lead, and certain other metals as well as by the roasting of arsenopyrite and arsenic sulfide ores. Arsenious oxide provides the starting material for most other arsenic compounds. It is also utilized in pesticides and serves as a decolorizer in the manufacture of glass and as a preservative for hides. Arsenic pentoxide is formed by the action of an oxidizing agent (e.g., nitric acid) on arsenious oxide. It comprises a major ingredient of insecticides, herbicides, and metal adhesives.

Arsine (AsH_3), a colourless poisonous gas composed of arsenic and hydrogen, is another familiar arsenic compound. The gas, also called arsenic hydride, is produced by the hydrolysis of metal arsenides and by the reduction by metals of arsenic compounds in acidic solutions. It has been used as a doping agent for semi-conductors and as a military poison gas. Arsenic compounds of particular importance in agriculture are arsenic acid (H_3AsO_4) and such salts as lead arsenate (PbHAsO_4) and calcium arsenate [$\text{Ca}_3(\text{AsO}_4)_2$], which are useful for sterilizing soils and controlling pests, respectively.

Arsenic also forms numerous organic compounds, as for example tetramethyldiarsine, $(\text{CH}_3)_2\text{As}-\text{As}(\text{CH}_3)_2$, used in preparing the common desiccant cacodylic acid. Several complex organic compounds of arsenic have been employed in the treatment of certain diseases, such as amebic dysentery, caused by microorganisms.

atomic number	33
atomic weight	74.9216
melting point (gray form)	814° C (1,497° F) at 36 atmospheres pressure
density (gray form)	5.73 g/cc at 14° C (57° F)
(yellow form)	2.03 g/cc at 18° C (64° F)
oxidation states	-3, +3, +5
electron config.	2-8-18-5 or $1s^2 2s^2 2p^6 3s^2$ $3p^6 3d^{10} 4s^2 4p^3$

arsenic poisoning, harmful effects of various arsenic compounds on body tissues and functions. Arsenicals are used in numerous products, including insect, rodent, and weed killers, some chemotherapeutic agents, and certain paints, wallpaper, and ceramics.

Arsenic poisoning in humans most often results from the ingestion or inhalation of insecticides containing arsenious oxide, copper acetoarsenite, or calcium or lead arsenate. Exposure may be accidental, especially among children, or may be an occupational hazard, especially among agricultural workers handling insecticidal sprays and dusts. The sprayed fruits and vegetables, if not washed, may also bear enough arsenic to be potentially toxic to the consumer. Among industrial workers, arsine may be a source of acciden-

tal poisoning. Poisoning may also result from prolonged treatment with such medications as Fowler's solution (potassium arsenate) and arsphenamine.

Arsenic is believed to exert its toxicity by combining with certain enzymes (the organic catalysts of the cell), thereby interfering with cellular metabolism.

Individual susceptibility to arsenic poisoning varies widely; some persons have been known to develop a tolerance to doses that would kill others. Poisoning may result from a single large dose (acute poisoning) or from repeated small doses (chronic poisoning). Symptoms of acute poisoning from swallowing arsenic include nausea, vomiting, burning of the mouth and throat, and severe abdominal pains. Circulatory collapse may occur and be followed by death within a few hours. In persons exposed to arsine, the outstanding effects are destruction of red blood cells and damage to the kidneys. With chronic exposure, the more common effects include gradual loss of strength; diarrhea or constipation; pigmentation and scaling of the skin, which may undergo malignant changes; nervous manifestations marked by paralysis and confusion; degeneration of fatty tissue; anemia; and the development of characteristic streaks across the fingernails. The criminal use of the colourless, tasteless compound arsenious oxide as a poison was common until chemical methods of detection were developed. Definitive diagnosis of arsenic poisoning is based on the finding of arsenic in the urine and in hair or nails.

The treatment of acute arsenic poisoning involves washing out the stomach and the prompt administration of dimercaprol (BAL).

arsenide, any member of a rare mineral group consisting of compounds of one or more metals with arsenic (As). The coordination of the metal is almost always octahedral or tetrahedral. In the former case, each metal ion occupies a position within an octahedron composed of six oppositely charged arsenic ions, whereas in the latter each of the metal ions is surrounded by six oppositely charged neighbours arranged tetrahedrally. Structurally the arsenides resemble the sulfides (e.g., galena, sphalerite, and argentite) and one frequently included in that mineral group (see sulfide).

Two common arsenides are niccolite (NiAs) and skutterudite (CoAs_3). Niccolite is a low-temperature hydrothermal mineral with hexagonal symmetry that is usually associated with nickel, cobalt, and silver sulfides. Skutterudite, on the other hand, is an intermediate- to high-temperature hydrothermal mineral with cubic symmetry associated with arsenopyrite, native silver, and bismuth. Other arsenides include:

maucherite	$\text{Ni}_{11}\text{As}_8$
rammelsbergite	NiAs_2
smaltite	$(\text{Co,Ni})\text{As}_{3-x}$
safflorite	$(\text{Co,Fe})\text{As}_2$
löllingite	FeAs_2
arsenopalladinite	Pd_3As
dienerite	Ni_3As
oregonite	Ni_2FeAs_2
algodonite	Cu_6As
sperryllite	PtAs_2

All arsenides have a metallic lustre, are opaque, and have high specific gravity and intermediate to low hardness. The succession of arsenide minerals maucherite, niccolite, rammelsbergite, smaltite, skutterudite, safflorite, and löllingite corresponds to the transition from a reducing to an oxidizing environment.

Arsenius THE GREAT, also called **ARSENIOUS OF ROME** (b. c. 354, Rome—d. c. 455, Troe, Scete Desert, Egypt), Roman noble, later monk of Egypt, whose asceticism among the Christian hermits in the Libyan Desert caused him to be ranked among the celebrated Desert Fathers and influenced the development of

the monastic and contemplative life in Eastern and Western Christendom.

Born of a Roman senatorial family, Arsenius probably was made a deacon by Pope Damasus. Recommended by Damasus c. 383, he was called to the court of Emperor Theodosius I the Great (ruled 379–395) in Constantinople and entrusted with the education of Theodosius' sons Arcadius and Honorius. After 11 years of tutoring, Arsenius retired to the eremitical life on Mount Scete in the Libyan Desert. Shortly afterward, he was forced to flee to Troe, near ancient Memphis, Egypt, in order to escape the devastating incursions of the Libyan Mazici tribesmen, whom he likened to the Goths and Huns who ravaged Rome. Following an odyssey of approximately 15 years throughout the Egyptian wilderness, he died in the desert of Scete. He was reputed to have lived for more than 100 years. His tall, lean appearance, as described by his biographer and monastic disciple, Daniel, reinforced his fame as an ascetic. Byzantine historians and monastic writers attribute various maxims and conferences to Arsenius, many of which are contained in the 5th-century anthology *Apophthegmata patrum* ("Sayings of the Fathers"). His principal works include the *Didaskalia kai parainesis* ("Instruction and Exhortation"), which was written as a guideline for monks and is evidence, according to 6th-century historians, that he was an abbot or spiritual leader of a religious community. His commentary on the Gospel According to Luke, *Eis ton peirastēn nomikon* ("On the Temptation of the Law"), in effect is also a treatise on asceticism and the contemplative life. These texts are contained in the series *Patrologia Graeca*, vol. 65–66 (1857–66), edited by J.-P. Migne.

Arsenius is honoured as a saint by the Greek Orthodox Church and the Syro-Maronites (an Eastern Syrian church in union with Rome). His feast day is July 19.

Arsenius Autorianus (b. c. 1200, Constantinople—d. 1273, Proconnesus, Tur.), patriarch of Constantinople, whose deposition caused a serious schism in the Byzantine Church. He took the name Arsenius on being appointed patriarch of Nicaea in 1255 by the Byzantine emperor Theodore II Lascaris. In 1259 he crowned John IV, Theodore's son and legitimate heir, and Michael VIII Palaeologus as co-emperors. Arsenius retired to a monastery when Michael extruded John from authority, but he was persuaded to return to office after Constantinople had been liberated from the Latins in 1261. When Michael banished and blinded John, Arsenius excommunicated the Emperor and was consequently deposed by him in 1265. He was exiled to Proconnesus, where he wrote a testament that has served as an important source of contemporary history.

After Arsenius' deposition, the empire was split into two factions known as the Arsenites (followers of Arsenius) and the Josephists (followers of Joseph, Arsenius' second successor). The Arsenites fanatically opposed Michael's pro-Latin policy, which culminated at the second Council of Lyon in 1274, when papal supremacy over the Greek Church was accepted by Michael's legates. The Arsenite schism continued after the council had been rejected by the Byzantines and officially abandoned as imperial policy, and it did not end until 1310, when the body of Arsenius was buried by Patriarch Niphon in Hagia Sophia, the primatial church in Constantinople.

arsenopyrite, also called **MISPICKEL**, an iron sulfoarsenide mineral (FeAsS), the most common ore of arsenic. It is most commonly found in ore veins that were formed at high temperatures, as at Mapimí, Mex.; Butte, Mont.; and Tunaberg, Swed. Arsenopyrite forms monoclinic or triclinic crystals with an orthorhombic shape; the physical appearance

of these crystals is seldom an accurate method for determining their symmetry. A series of minerals in which cobalt partially replaces iron is called cobaltian arsenopyrites; those in which the Co:Fe ratio lies between 1:2 and 6:1 are called glaucodot (*see also* cobaltite). Weathering alters these sulfides to arsenates: arsenopyrite to scorodite, and glaucodot to erythrite. For detailed physical properties, *see* sulfide mineral (table).

Arses (d. June 336 BC), Achaemenid king of Persia (reigned November 338–June 336 BC); he was the youngest son of Artaxerxes III Ochus and Atossa.

Arses had been placed on the throne by the eunuch Bagoas, who had murdered Arses' father and all his brothers. Little is known of Arses' short reign; the major external event was the invasion of Asia Minor by Philip II of Macedon, ostensibly because Arses refused to make reparation to Philip for Artaxerxes' aid to the city of Perinthus against Philip.

The young Arses objected to the tyrannical control by Bagoas and attempted to poison him. Instead, Arses and all his children were killed, and Bagoas gave the throne to a collateral heir, Darius III.

arsine, colourless, extremely poisonous gas composed of arsenic with hydrogen (*see* arsenic).

Arsinoe, also spelled ARSINOË, name of four queens of the Ptolemaic dynasty of Egypt, grouped below chronologically and indicated by the symbol •.

• **Arsinoe I** (fl. early 3rd century BC), queen of Egypt, daughter of Lysimachus, king of Thrace, and first wife of Ptolemy II Philadelphus. Although she bore Ptolemy three children, including his successor, she was unable to prevent him from repudiating her and marrying his sister, Arsinoe II.

Arsinoe I was married to Ptolemy about 282 as part of the alliance between Thrace and Egypt against Seleucus I Nicator of Syria. Three years later, Philadelphus' ambitious sister arrived in Egypt, and, probably at her instigation, charges of conspiring to assassinate Ptolemy were soon brought against Arsinoe. She was banished to Coptos, a city of Upper Egypt near the Wadi Hammamat, while her rival married Ptolemy and adopted her children.

Arsinoe survived at Coptos, where a stela referring to her has been found; on it she is called king's wife, but her name is not enclosed in the royal cartouche (an oval figure on monuments enclosing a sovereign's name), as is customary for a queen.

• **Arsinoe II** (b. c. 316 BC—d. July 270 BC), daughter of Berenice and Ptolemy I Soter, founder of the Macedonian (Ptolemaic) dynasty in Egypt; as queen of Thrace and later wife of her brother, King Ptolemy II Philadelphus of Egypt, she ruthlessly used her two husbands to advance her own position and eventually wielded great power in both kingdoms.

In 300 BC Arsinoe was married to Lysimachus, the king of Thrace, who renamed Ephesus after her and gave her three cities on the Black Sea, as well as Cassandrea, a city in northern Greece. She strove to secure the succession of the Thracian kingdom for the eldest of her three sons by accusing the heir apparent, Agathocles, the king's son by an earlier marriage, of plotting to kill his father. When the old and suspicious king ordered him executed, an ally of Agathocles in Asia Minor, the governor of Pergamum, requested aid from the Seleucid ruler Seleucus I Nicator, and war broke out between Thrace and the Middle Eastern Seleucid kingdom. After Ly-

simachus' death in battle (281), Arsinoe fled to Cassandrea. After assassinating Seleucus, Ptolemy Ceraunus (Arsinoe's half brother) cajoled her into marrying him, but, on entering Cassandrea, he promptly executed her two younger sons. Arsinoe escaped and eventually went to Alexandria (c. 279) to advance her fortune.

Arsinoe II, coin, 270–250 BC; in the British Museum
By courtesy of the trustees of the British Museum

Soon after her arrival in Egypt, Ptolemy II's first queen was accused, probably at Arsinoe's instigation, of plotting his murder and was exiled. Arsinoe then married her own brother (c. 277), a customary practice in Egypt but scandalous to the Greeks. "Philadelphoi" ("Brother-Loving") consequently was added to the names of Ptolemy and Arsinoe.

Arsinoe's influence in the Egyptian government grew very swiftly. She contributed to Ptolemy's victory in the First Syrian War (274–271 BC) between Egypt and the Seleucid realm. Argaeus, Ptolemy's brother, and a half brother were executed on the familiar charge of conspiracy.

Arsinoe shared all of Ptolemy's titles, appeared on the coinage alone and with her husband, and had her own throne name. Towns were named after her in Greece, and dedications to her were made at numerous places in Greece and Egypt.

According to Egyptian custom, which recognized the living rulers as deities in their own right, Arsinoe was probably deified within her lifetime. After her death in 270, her cult was established in numerous places, including Alexandria, the Ptolemaic capital, where a great shrine, the Arsinoeion, was dedicated to her. Toward the end of Ptolemy II's reign, a province, Al-Fayyūm, southwest of Cairo, where the king had done much land reclamation, was renamed in her honour as the Arsinoite province.

• **Arsinoe III** (b. c. 235—d. c. 204 BC), daughter of Queen Berenice II and Ptolemy III Euergetes of Egypt, sister and wife of Ptolemy IV Philopator. Powerless to arrest the decline of the Ptolemaic kingdom under her debauched

Arsinoe III, coin, late 3rd century BC; in the British Museum

By courtesy of the trustees of the British Museum, photograph J.R. Freeman & Co. Ltd

husband's rule, the popular queen was eventually murdered by the royal ministers.

In 217 Arsinoe accompanied her brother to Raphia in Palestine, reputedly encouraging the Egyptian troops before their victorious encounter with the army of the Middle East-

ern Seleucid kingdom. Married to Ptolemy after the battle, she gave birth to the future Ptolemy V Epiphanes about 210. Thereafter she was sequestered in the palace, while Ptolemy's depraved male and female favourites ruined both king and government. Although Arsinoe apparently disapproved of the sordid state of the court, she was unable to exert any influence. Ptolemy IV Philopator died in 205, and his ministers, fearing retribution from Arsinoe, arranged her murder about a year later. Neither the king's nor the queen's death was announced until the child Ptolemy had been enthroned. Arsinoe had attained some popularity, and rioting followed the news of her assassination.

• **Arsinoe IV** (b. c. 63 BC—d. 41 BC), youngest daughter of the Macedonian king Ptolemy XII Auletes of Egypt, sister of Cleopatra VII and the kings Ptolemy XIII and XIV. During the Alexandrian war, Arsinoe attempted to lead the native forces against Cleopatra, who had allied herself with Julius Caesar.

Upon landing in Alexandria in 48, Caesar captured the members of the Ptolemaic royal family, but Arsinoe managed to escape with the aid of Ganymedes, her mentor, and joined the Egyptian army headed by Achilles. Following a feud between Ganymedes and the Egyptian commander, Arsinoe ordered Achilles executed. Ganymedes pressed Caesar's forces hard and negotiated an exchange of Arsinoe for Ptolemy XIII, but the Romans, with reinforcements, defeated the Egyptian army, and Arsinoe was sent to Rome to be led in Caesar's triumph. After this humiliation Arsinoe found sanctuary in the Temple of Artemis at Ephesus, in Asia Minor, for she feared her ambitious sister, Cleopatra, after securing the affections of the Roman triumvir Mark Antony, in 41 persuaded him to execute Arsinoe.

Epoch (which occurred from 36.6 to 23.7 million years ago).

The animal, probably a swamp dweller, reached a length of about 3.5 m (11 feet), and was about the size of a large rhinoceros. It carried an enormous pair of horns on the nasal bones and an additional, smaller pair of horns on the frontal bones.

Arsiantepe (Turkey): *see* Milid.

arson, crime commonly defined by statute as the malicious and voluntary burning of the

property of another without his consent. Limited in English common law to the burning of dwellings under circumstances that endangered human life, the definition of arson has been expanded by modern statutes and now includes acts dangerous to property itself.

In nearly all countries but Great Britain, if an arson causes death, the arsonist is guilty of murder even though he did not intend to kill. But the definition of arson has been so expanded that most jurisdictions have divided arson statutes into two or more degrees, reserving the heavier punishments for those burnings that pose a danger to human life. Usually, those include the burning of habitable dwellings such as houses, stores, or factories, as well as vehicles, bridges, or trees. Germany and some states of the United States also impose a higher penalty for arson committed for the purpose of concealing or destroying evidence of another crime.

Lighter penalties are assigned to the new categories of arson endangering primarily property. Thus, it is arson to burn personal as well as real property or for a person to burn his own house to defraud an insurance company. Furthermore, modern statutes have forbidden burnings caused by newly invented incendiary devices.

A fire caused by accident or ordinary carelessness is not arson, because maliciousness is lacking. A person may be guilty of arson, however, if he acts recklessly and disregards the consequences. An arsonist's motive is often irrelevant if he acts voluntarily and without the consent of the owner of the property. Under some legal standards for insanity, it may be a defense that the actor suffered from pyromania, an irresistible urge to set fires.

Arsonval, Arsène d', in full JACQUES-ARSENÈ D'ARSONVAL (b. June 8, 1851, La Borie, Fr.—d. Dec. 31, 1940, La Borie), French physician and physicist known for his researches in electrotherapy.

Arsonval studied at the University of Poitiers and at Limoges and Paris, becoming a doctor of medicine in 1877. In 1882 he was named director of the Laboratory of Biological Physics of the Collège de France, Paris, where he was appointed professor in 1894.

Arsonval's early research into animal heat, muscle contraction, and electrophysiology led to his invention of devices used to treat diseases through electricity. He introduced the first reflecting moving-coil galvanometers used to measure weak electric currents (1882), invented mechanisms to obtain high-frequency currents used to treat diseases of the skin and mucous membranes ("d'Arsonvalization"; 1890), and demonstrated how a human being could conduct an alternating current strong enough to light an electric lamp (1892).

Arsouf, Battle of (1191): *see* Arsūf, Battle of.

arsphenamine, early chemotherapeutic drug, an arsenical (chemical agent containing arsenic) that was discovered by the founder of chemotherapy, the German bacteriologist Paul Ehrlich, and was marketed by him under the trade name Salvarsan. First prepared by Ehrlich in 1909, arsphenamine was the most effective drug for the treatment of syphilis until the discovery of the antibiotic penicillin in 1928. It has since been completely replaced in medicine by numerous other drugs less toxic to the human body.

Arsūf, Battle of, Arsūf also spelled ARSOUF, famous victory won by the English king Richard I the Lion-Heart during the Third Crusade.

Richard, having taken Acre in July 1191, was marching to Joppa (Jaffa), but the Muslim army under Saladin slowed down the cru-

saders' progress when they advanced from Caesarea, which they left on September 1. On September 7, after the crusaders had left Arsūf, the Muslim attacks became more intensive and were concentrated against the Hospitalers, Richard's rear guard, whom Richard forbade to counterattack until the evening. He then launched a general charge that overwhelmed Saladin's army and inflicted heavy losses on the forces attacking to the rear. Seven hundred crusaders and several thousand Muslims were killed. The victory at Arsūf enabled the crusaders to occupy Joppa but was not a crushing blow to the Muslims. Saladin was able to regroup his forces, which the crusaders had not pursued for fear of ambushes. From September 9 the Muslims renewed their harassing tactics, and Richard did not dare to push on to Jerusalem.

art, the use of skill and imagination in the creation of aesthetic objects, environments, or experiences that can be shared with others. The term art may also designate one of a number of modes of expression conventionally categorized by the medium utilized or the form of the product; thus we speak of painting, sculpture, filmmaking, music, dance, literature, and many other modes of aesthetic expression as arts and of all of them collectively as the arts. The term art may further be employed in order to distinguish a particular object, environment, or experience as an instance of aesthetic expression, allowing us to say, for example, that *that* drawing or tapestry is art.

Traditionally, the arts are divided into the fine and the liberal arts. The latter are concerned with skill of expression in language, speech, and reasoning. The fine arts, a translation of the French *beaux-arts*, are more concerned with purely aesthetic ends, or, in short, with the beautiful. Many forms of expression combine aesthetic concerns with utilitarian purposes; pottery, architecture, metalworking, and advertising design may be cited as examples. It may be useful to conceive of the various arts as occupying different regions along a continuum that ranges from purely aesthetic purposes at one end to purely utilitarian purposes at the other. This polarity of purpose is reflected also in the related terms artist and artisan, the latter understood as one who gives considerable attention to the utilitarian. This should by no means be taken as a rigid scheme, however. Even within one form of art,

motives may vary widely; thus a potter or a weaver may create a highly functional work—a salad bowl, for example, or a blanket—that is at the same time beautiful, or he may create works that have no purpose whatever beyond being admired.

Another traditional system of classification, applied to the fine arts, establishes such categories as literature (including poetry, drama, story, and so on), the visual arts (painting, drawing, sculpture, etc.), the graphic arts (painting, drawing, design, and other forms expressed on flat surfaces), the plastic arts (sculpture, modeling), the decorative arts (enamelwork, furniture design, mosaic, etc.), the performing arts (theatre, dance, music), music (as composition), and architecture (often including interior design).

Art is treated in a number of articles in the MACROPAEDIA. For general discussions of the foundations, principles, practice, and character of art and the arts, *see* Aesthetics; Folk Arts; Philosophies of the Branches of Knowledge.

For surveys of the traditional categories of art, *see* the articles referred to in the MICROPAEDIA entries architecture; dance; decorative art; drawing; literature; music; painting; sculpture; theatre.

For discussions of other types of art, *see* Broadcasting; Marketing and Merchandising; Masks; Motion Pictures; Photography; Printmaking; Rhetoric; Writing. For treatments of the various arts as practiced by non-European peoples and cultures, *see* African Arts; American Peoples, Arts of Native; Central Asian Arts; East Asian Arts; Egyptian Arts and Architecture, Ancient; Islāmic Arts; Oceanic Arts; Prehistoric Peoples and Cultures; South Asian Arts; Southeast Asian Arts.

For a description of the place of art in the circle of learning and for a list of both MACROPAEDIA and MICROPAEDIA articles on the subject, *see* PROPAEDIA: Part Six.

art, academy of, in the visual arts, institution established primarily for the instruction of artists but often endowed with other functions, most significantly that of providing a place of exhibition for students and mature artists accepted as members. In the late 15th and early 16th centuries, a series of short-lived "academies" that had little to do with artistic training were founded in various parts of Italy. The most famous of these was the Accademia of Leonardo da Vinci (established 1498), which seems to have been simply a social gathering of amateurs meeting to discuss the theory and practice of art. The first true academy for instruction, the Academy of Design, was established in 1562 in Florence by the duke Cosimo I de' Medici at the instigation of the

"The Royal Academy of Arts," mezzotint by Richard Earlom (1742/43–1822), after J. Zoffany

By courtesy of the Victoria and Albert Museum, London

painter and art historian Giorgio Vasari. The two nominal heads of the institution were Cosimo himself and Michelangelo. In contrast to the guilds, membership in the Accademia del Disegno was an honour conferred only on already-recognized independent artists. When Vasari's academy fell into disorganization, his ideas were taken up by the Accademia di San Luca, founded in 1593 at Rome by the painter Federico Zuccari and Cardinal Federico Borromeo. With its emphasis on instruction and exhibition, the Accademia di San Luca was the prototype for the modern academy. Among its functions, much-imitated in later academies, was the sponsorship of lectures given by members of the academy and later published and made available to the general public. Such discourses became the means by which academies fostered and gained public acceptance for particular aesthetic theories. The Accademia di San Luca was firmly established by 1635, having received support from the powerful Pope Urban VIII. All the leading Italian artists and many foreigners were members; the secondary aims of the institution—to obtain important commissions, to enhance the prestige of the members, and to practice exclusionary policies against those who were not members—were avidly pursued.

For the following two centuries, academism dominated Italian artistic life. The decline of the church and then of aristocrats as patrons—those groups had formerly commissioned the painting of whole rooms at a time—resulted in the abandonment of the artist to an anonymous market of buyers who might commission one portrait or some other single easel painting at a time. This made exhibition essential to the artist's success. The state-supported academy, being the only institution financially able to provide this service on a large scale, came to control public taste, the economic fortunes of the artist, and ultimately the quality of his art by its determination of standards in the work it chose to show.

In France the Académie Royale de Peinture et de Sculpture was founded in 1648 as a free society of members all entitled to the same rights and granted admission in unlimited numbers. Under the sponsorship of the powerful minister Jean Baptiste Colbert and the direction of the painter Charles Le Brun, however, the Académie Royale began to function as an authoritarian arm of the state. As such, it assumed almost total control of French art and began to exercise considerable influence on the art of Europe. For the first time, the concept of aesthetic orthodoxy obtained official endorsement. The Académie achieved a virtual monopoly of teaching and exhibition in France, beginning in 1667 the long-lived series of periodic official art exhibitions called Salons. Thus, the idea, born of the Enlightenment, that aesthetic matters could be universally subjected to reason led to a rigid imposition of a narrow set of aesthetic rules on all art that came within the Académie's jurisdiction. This approach found especially fertile ground in the Neoclassical style, which arose in the second half of the 18th century and which the Académie espoused with enthusiasm.

Meanwhile, numerous academies, usually state-supported and similar in structure and approach to the French Académie, were established throughout Europe and in America. By 1790 there were more than 80 such institutions. One of the most important to be founded was the Royal Academy of Arts in London, established in 1768 by George III with Sir Joshua Reynolds as its first president. Although Reynolds gave the obligatory discourses on the importance of harmony and uplifting conceptions in painting, the Royal Academy never dominated art as completely as academies on the European continent.

The first important challenge to the power of the academies came with the rise of Ro-

manticism, which saw the artist as an individual genius whose creative powers could not be taught or externally controlled. Although most notable Romantic artists were absorbed into the academic system in the first half of the 19th century, eventually almost all artists of significance found themselves excluded from official patronage, largely because of the widening gap between their achievements and the taste of the bourgeois public to which the academies catered. The blow that finally broke the power of the academy was struck in France. After a series of unsuccessful compromises (e.g., the Salon des Refusés, established in 1863 by Napoleon III for painters excluded from the Académie), the Impressionists, who exhibited independently between 1874 and 1886, succeeded in winning the complete acceptance of the critics. In the 20th century the art academy has become an important source of instruction, synonymous with the modern art school.

art, popular: see popular art.

art brut (French: "raw art"), art of the French painter Jean Dubuffet, who in the 1940s pro-

"Dame aux fourrures," art brut painting by Jean Dubuffet, oil, September 1954; in the Mr. and Mrs. Ralph F. Colin Collection, New York City

By courtesy of Mr. and Mrs. Ralph F. Colin, New York City

moted art that is crude, inexperienced, and even obscene. Dubuffet, the most important French artist to emerge after World War II, became interested in the art of the mentally ill in mid-career, after studying *The Art of the Insane* by the Swiss psychiatrist Hans Prinzhorn. Dubuffet applied the name art brut to the drawings, paintings, and doodlings of the psychotic, the naive, and the primitive, works that he regarded as the purest forms of creative expression. Like the early Cubists' discovery of primitive Oceanian and African sculpture, Dubuffet's study of this type of art gave him the inspiration he sought for his own art, as it represented for him the most authentic expression of emotion and human values.

Originally inspired by the childlike art of the Swiss painter Paul Klee, from the 1940s on, Dubuffet's paintings emulated the sincerity and naiveté that he associated with real art brut. The first of these works shows a childlike vision of humanity and civilization, with bright, gay colours and naive drawing. Later works, passionate and primitive, sometimes pathetic, sometimes obscene, incorporate forms derived from graffiti and psychotic art; painted in thick impasto or constructed in collage, these densely detailed and intensely expressive works convey a sense of teeming life and brutal force.

art collection, an accumulation of works of art by a private individual or a public institution. Art collecting has a long history, and most of the world's art museums grew out of great private collections formed by royalty, the aristocracy, or the wealthy.

A form of art collecting existed in the earliest civilizations—Egypt, Babylonia, China, and India—as arrays of precious objects and artworks stored in temples, tombs, and sanctuaries, as well as in the palaces and treasuries of kings. Such collections frequently displayed booty taken from conquered peoples and served to exalt the power and glory of a king or a priestly caste, rather than to display art objects for their innate significance. A taste for art collecting per se first developed in the West among the Greeks in the Hellenistic Age (4th–1st century BC) as they came to value art of previous stylistic periods for its own sake, rather than for its religious or civic significance. It was only with the rise of Rome, however, that art collecting came into its own. From the late 3rd century BC onward, as the Romans expanded eastward and southward, they plundered Greek cities of their artworks and sent these trophies back to Rome, thus stimulating a growing awareness and appreciation of Greek art. Wealthy Romans formed collections of Greek sculptures and paintings and commissioned copies to be made if the originals were beyond their reach. A voluminous trade in copies and fakes arose in order to satisfy the insatiable demand for Greek art. Gaius Verres, Lucullus, Pompey, and Julius Caesar were among the most important Roman collectors, as were the emperors Nero and Hadrian.

European interest in art lapsed during the Middle Ages, and the monasteries became the main repositories of cultural objects. But the Italian humanists' rediscovery of the classical Greco-Roman cultural heritage during the Renaissance renewed interest in antique art and the collecting of it. The Medici family of Florence, the Gonzagas of Mantua, the Montefeltros of Urbino, and the Estes in Ferrara assembled collections of antique sculpture in addition to works of contemporary art by the great painters of the age. These princely Italian collectors were followed in the 17th century by those of Cardinals Richelieu, Colbert, and Mazarin of France; Archduke Leopold William and Kings Philip III and IV of Spain; the Duke of Buckingham, the Earl of Arundel, and Charles I of England; and Queen Christina of Sweden. One of the most important art sales in history took place in 1627, when Charles I of England purchased (for £80,000) the art holdings accumulated by the dukes of Mantua (though this collection was subsequently dispersed during the English Civil Wars). Cardinal Colbert spent vast sums of money building the royal art collection of the Louvre (opened 1681).

During the 18th century nonaristocratic collectors, such as Pierre Crozat, Horace Walpole, and the Fugger banking family were able to form important collections. Meanwhile, the great private collections of Europe's royalty began to be opened to public viewing, and eventually monarchs and aristocrats began donating their holdings to the public. The first notable example of this was Maria Ludovica, the grand duchess of Tuscany and last of the Medicis, who in 1737 bequeathed her family's vast art holdings to the state of Tuscany; they now form the core of the Uffizi Gallery, the Pitti Palace, and the Laurentian Library in Florence. Maria Ludovica was followed by many other monarchs and aristocratic collectors, and the great art museums that opened all over Europe in the late 18th and 19th centuries were based on collections their owners had ceded to the state. The movement of art-

works from private collections into museums has been a dominant feature of art collecting ever since.

Wealthy industrialists came to supplant aristocrats as the preeminent collectors in the 19th century, with Americans assuming a particularly prominent role in this regard. J.P. Morgan, Henry Clay Frick, and Andrew Mellon were among those Americans who combined great wealth with artistic discernment. The 19th and early 20th centuries saw an unprecedented flow of art masterpieces from Europe to the United States, where they ended up in that nation's great art museums. Other important collectors in the 19th and 20th centuries depended on shrewd and present artistic judgment rather than on immense financial resources. Among such visionaries were Victor Choequet (a minor French government official who was an important patron of the Impressionists) in the late 19th century and the dealer-collectors Paul Durand-Ruel, Ambroise Vollard, and Daniel-Kenry Kahnweiler in the early 20th century. The volume and scope of art collecting have continued to expand in subsequent decades, resulting in ever-higher prices for works of art.

Art collecting in non-Western countries was primarily the province of royalty, nobles, and religious institutions. Some of the Chinese emperors accumulated vast numbers of artworks, for instance, and though these collections tended to be dispersed or even destroyed upon the overthrow of successive dynasties, the collection built up by Ch'ien-lung (reigned 1735–96) and subsequent Ch'ing emperors came to form the nucleus of two great art museums, the National Palace Museum in Taiwan and the Palace Museum in Peking. In Japan, Buddhist monasteries were important repositories for artworks during the feudal period and afterward, and their collections eventually enriched the Tokyo National Museum and other modern Japanese institutions. The royal private collection of King Mongkut of Siam (reigned 1851–68) forms the core of the Bangkok National Museum of Thailand. Middle Eastern rulers also collected art, but less is known about their collections, which tended to be dispersed after the ruler's death or the overthrow of his dynasty.

art conservation and restoration, any attempt to repair and preserve works of sculpture, painting, drawing, architecture, and the decorative arts (furniture, glassware, metalware, textiles, ceramics, and so on) from the effects of negligence, willful damage, or, more usually, inevitable decay caused by the effects of time and human use on the materials of which they are made. Ceramics, glassware, and gold are exceptionally durable, but artifacts in other materials are more susceptible to dampness, corrosion, and changes in atmosphere that cause warping and cracking; attacks by insects, fungi, and frost; tearing and staining; and the effects of simple aging or, if they are kept out of doors, weathering, effects that are likely to be compounded by the industrial atmosphere.

A brief treatment of art conservation follows. For full treatment, see MACROPAEDIA: Art Conservation and Restoration.

Paintings are the most frequently and widely restored of all art objects. Paintings on wood panels may require straightening, because the panel may have warped and become bent convexly at the front (painted) surface. Such panels are reinforced at the back, or the paint surface is removed from the panel and transferred to a new canvas backing. In the case of paintings on canvas that has deteriorated, the old canvas is attached at its back surface to a new canvas in a process that is known as relining; the two canvases are sealed together

with a thermoplastic cement. Areas of paint that have cracked, flaked, or lifted off the backing are fixed to the canvas with special adhesives or, alternatively, by relining the entire canvas. Areas in which the paint has been severely damaged or is entirely gone can be restored by inpainting—*i.e.*, by applying new paint to those areas while carefully matching the technique and paint texture employed by the original artist. Darkened and discoloured varnishes are removed from a painting's surface with the use of alcohol solvents; this painstaking process constitutes the single most frequently practiced type of painting restoration.

Sculpture restoration is a burgeoning field of activity, mostly because the moisture-bound pollutants in the air of urban or industrialized areas tend to attack and dissolve the surfaces of stone sculptures. Restoration and conservation involve first cleaning the stone and then applying certain chemicals to it that waterproof and strengthen the stone to a depth of several inches, rendering it resistant to further decay.

The restoration of furniture, stained glass, textiles, and ceramics involves such techniques as replacing lost or broken elements from chairs and tables and substituting lost pieces of stained glass in a window; gluing broken pots or other ceramics together; impregnating the wood in a piece of furniture with special chemicals that protect it from the atmosphere and from fungi and insects; and washing and cleaning valuable textiles.

Architectural restoration can involve stabilizing a building's foundation or structural elements through the use of concrete and of metal rods; repairing and waterproofing sections of a building that have been damaged by water or dampness; reinforcing a building's walls or roof; and cleaning and protecting a building's stonework, brickwork, or other forms of exterior decoration.

The field of art restoration has always been marked by controversies, many of which have arisen when art restorers tried to restore a damaged object to its "original" condition when that condition was unknown or uncertain to begin with. Nowhere did such controversies rage more fiercely than in the 19th century in the field of architectural restoration. In the late 18th and early 19th centuries, its purpose was to impose unity of style—the style, in general, being Gothic. Where more than one medieval style was present, the architect would make a choice (commonly in favour of Decorated). This practice of "restoring" buildings to the style of periods especially favoured by the restorer came to be regarded by the middle of the 19th century as a falsification of history. Gradually the creed "conserve, but not rebuild" prevailed in Europe; and by 1900 it had started to be enforced by government legislation. Laws enacted in the 20th century and the success of foundations such as the National Trust of England to preserve historic buildings reflect not only an increasing concern but also an ever-widening view of the kind of building coming within the scope of such protection. In the United States both the National Trust for Historic Preservation and the National Park Service have somewhat similar functions.

art criticism, the description, interpretation, and evaluation of works of art. Art criticism is concerned with judging the aesthetic value or quality of art objects in such fields of the visual arts as painting, sculpture, the decorative arts, drawing, printmaking, and photography. Art criticism is linked with aesthetics (the evaluation of beauty and of art in general), since art critics frequently assess particular works of art in accordance with some presupposed criterion of aesthetic value, thus putting aesthetic theory into practical application.

Art criticism encompasses a wide variety of

approaches, ranging from rigorously logical critical judgments based on philosophically derived aesthetic criteria to more personal and subjective reactions that attempt to communicate to the reader some of the emotions inspired in the critic by viewing the work of art.

A brief treatment of art criticism follows. For full treatment, see MACROPAEDIA: Art Criticism, The History of.

Art criticism in the West before the 19th century frequently consisted of broad generalizations about art's moral purposes and higher ideals (truth, beauty, etc.) rather than of a close and demanding scrutiny of individual works of art. But in the 19th century, commercial art galleries came into being to cater to the growing art market represented by the emerging middle class, and newspapers with wide circulations appeared through which art criticism could be disseminated to that public en masse. Art critics thus began functioning as tastemakers for the new art-buying public, and these critics began to focus in on specific artists and their works in an effort to determine their relative merits and worth.

In the 20th century, the breakdown of established conceptions of meaning in the visual arts and the many rapid changes of artistic style enabled certain perceptive critics to attain the role of champions of new artistic movements. The English critic Roger Fry helped accustom the public to the Postimpressionist movement (which he himself named), and the American critics Clement Greenberg and Harold Rosenberg did the same for Abstract Expressionism. By the late 20th century, art criticism encompassed a wide range of approaches, ranging from journalistic reportage to critiques grounded in Marxist, feminist, and linguistic theories. At the turn of the 21st century, art criticism had become a well-established if wildly diverse field.

Art Deco, also called **STYLE MODERNE**, movement in the decorative arts and architecture that originated in the 1920s and developed into a major style in western Europe and the United States during the 1930s. Its name was derived from the Exposition Internationale des Arts Décoratifs et Industriels Modernes, held in Paris in 1925, where the style was first exhibited. Art Deco design represented modernism turned into fashion. Its products included both individually crafted luxury items and mass-produced wares, but, in either case, the intention was to create a sleek and antitraditional elegance that symbolized wealth and sophistication.

The distinguishing features of the style are simple, clean shapes, often with a "streamlined" look; ornament that is geometric or stylized from representational forms; and unusually varied, often expensive materials, which frequently include man-made substances (plastics, especially bakelite; vita-glass; and ferroconcrete) in addition to natural ones (jade, silver, ivory, obsidian, chrome, and rock crystal). Though Art Deco objects were rarely mass-produced, the characteristic features of the style reflected admiration for the modernity of the machine and for the inherent design qualities of machine-made objects (*e.g.*, relative simplicity, planarity, symmetry, and unvaried repetition of elements).

Among the formative influences on Art Deco were Art Nouveau, the Bauhaus, Cubism, and Sergey Diaghilev's Ballets Russes. Decorative ideas came from American Indian, Egyptian, and early classical sources as well as from nature. Characteristic motifs included nude female figures, animals, foliage, and sunrays, all in conventionalized forms.

Most of the outstanding Art Deco creators designed individually crafted or limited-edition items. They included furniture designers Jacques Ruhlmann and Maurice Dufrené; architect Eliel Saarinen; metalsmith Jean

Puiforcat; glass and jewelry designer René Lalique; fashion designer Érté; artist-jewelers Raymond Templier, Jean Fouquet René Robert, H.G. Murphy, and Wiwen Nilsson; and the figural sculptor Chiparus. The fashion designer Paul Poiret and the graphic artist Edward McKnight Kauffer represent those whose work directly reached a larger audience. New York City's Rockefeller Center (especially its interiors supervised by Donald Deskey), the Chrysler Building by William Van Alen, and the Empire State Building by Shreve, Lamb & Harmon are the most monumental embodiments of Art Deco. Although the style went out of fashion during World War II, beginning in the late 1960s there was a renewed interest in Art Deco design.

art history, also called **ART HISTORIOGRAPHY**, historical study of the visual arts, being concerned with identifying, classifying, describing, evaluating, interpreting, and understanding the art products and historic development of the fields of painting, sculpture, architecture, the decorative arts, drawing, printmaking, photography, interior design, etc.

Art historical research has two primary concerns. The first is (1) to discover who made a particular art object (attribution), (2) to authenticate an art object, determining whether it was indeed made by the artist to whom it is traditionally attributed, (3) to determine at what stage in a culture's development or in an artist's career the object in question was made, (4) to assay the influence of one artist on succeeding ones in the historical past, and (5) to gather biographical data on artists and documentation (provenance) on the previous whereabouts and ownership of particular works of art. The second primary concern of art historical research is to understand the stylistic and formal development of artistic traditions on a large scale and within a broad historical perspective; this chiefly involves the enumeration and analysis of the various artistic styles, periods, movements, and schools of the past. Art history also involves iconography (*q.v.*), which is the analysis of symbols, themes, and subject matter in the visual arts, particularly the meaning of religious symbolism in Christian art.

Art historical scholarship depends greatly on the broad experience, intuitive judgment, and critical sensitivity of the scholar in making correct attributions. An extensive knowledge of the historical context in which the artist lived and worked is also necessary, as well as empathy with and understanding of a particular artist's ideas, experiences, and insights. Attribution plays a key role in art historical research, because when one art object can be conclusively authenticated (by a signature, contemporary accounts, or other forms of provenance), other works of a similar or closely related character can be grouped around it and assigned to that particular artist or period. This and other methods have been used to build up modern scholars' detailed and comprehensive understanding of art products and traditions extending into the remote past.

Art Institute of Chicago, in Chicago, Ill., museum of European, American, and Oriental sculpture, paintings, prints and drawings, and decorative arts, as well as photography and African and pre-Columbian American art. It was established in 1866 as the Chicago Academy of Design and took its current name in 1882. In 1893 it moved to its present building, designed by the architectural firm of Shepley, Rutan, and Coolidge. The museum is noted for its extensive collections of 19th-century French painting (Impressionist works in particular) and of 20th-century painting.

The institute also includes the School of the Art Institute, the Ryerson Library (art), and the Burnham Library (architecture). The Goodman Theatre (founded 1925) presents productions of the Chicago Theatre Group

(from 1977); the Goodman School of Drama, operated by the Art Institute from 1930 to 1978, became a school of DePaul University (Chicago) in the latter year.

Art Nouveau, ornamental style of art that flourished between about 1890 and 1910 throughout Europe and the United States. Art Nouveau is characterized by its use of a long, sinuous, organic line and was employed most often in architecture, interior design, jewelry and glass design, posters, and illustration. It was a deliberate attempt to create a new style, free of the imitative-historicism that dominated much of 19th-century art and design. Art Nouveau developed first in England and soon spread to the European continent, where it was called *Jugendstil* in Germany, *Sezessionstil* in Austria, *Stile Floreale* (or *Stile Liberty*) in Italy, and *Modernismo* (or *Modernista*) in Spain. The term Art Nouveau was coined by a gallery in Paris that exhibited much of this work.

In England the style's immediate precursors were the Aestheticism of the illustrator Aubrey Beardsley, who depended heavily on the expressive quality of organic line, and the Arts and Crafts Movement of William Morris, who established the importance of a vital style in the applied arts. On the European continent, Art Nouveau was also influenced by experiments with expressive line by the painters Paul Gauguin and Henri de Toulouse-Lautrec. The movement was also partly inspired by a vogue for the linear patterns of Japanese prints (*ukiyo-e*).

The distinguishing ornamental characteristic of Art Nouveau is its undulating, asymmetrical line, often taking the form of flower stalks and buds, vine tendrils, insect wings, and other delicate and sinuous natural objects; the line may be elegant and graceful or infused with a powerfully rhythmic and whiplike force. In the graphic arts the line subordinates all other pictorial elements—form, texture, space, and colour—to its own decorative effect. In architecture and the other plastic arts, the whole of the three-dimensional form becomes engulfed in the organic, linear rhythm, creating a fusion between structure and ornament. Architecture particularly shows this synthesis of ornament and structure: a liberal combination of materials—ironwork, glass, ceramic, and brickwork—was employed, for example, in the creation of unified interiors in which columns and beams became thick vines with spreading tendrils and windows became both openings for light and air and membranous outgrowths of the organic whole. This ap-

"The Whiplash," Art Nouveau tapestry by Hermann Obrist, silk embroidered on wool, 1895; in the Münchner Stadtmuseum, Munich
By courtesy of the Münchner Stadtmuseum, Munich

proach was directly opposed to the traditional architectural values of reason and clarity of structure.

There were a great number of artists and designers who worked in the Art Nouveau style. Some of the more prominent were the Scottish architect and designer Charles Rennie Mackintosh, who specialized in a predominantly geometric line and particularly influenced the Austrian *Sezessionstil*; the Belgian architects Henry van de Velde and Victor Horta, whose extremely sinuous and delicate structures influenced the French architect Hector Guimard, another important figure; the American glassmaker Louis Comfort Tiffany; the French furniture and ironwork designer Louis Majorelle; the Czechoslovakian graphic designer-artist Alphonse Mucha; the French glass and jewelry designer René Lalique; the American architect Louis Henry Sullivan, who used plantlike Art Nouveau ironwork to decorate his traditionally structured buildings; and the Spanish architect and sculptor Antonio Gaudí, perhaps the most original artist of the movement, who went beyond dependence on line to transform buildings into curving, bulbous, brightly coloured, organic constructions.

After 1910 Art Nouveau appeared old-fashioned and limited and was generally abandoned as a distinct decorative style. It was important, however, in moving toward the 20th-century aesthetic of unity of design.

art restoration: see art conservation and restoration.

Árta, city and capital, *nomós* (department) of Árta, Ípiros (ancient Epirus) region, Greece. It is situated on the left bank of the Arakthos

Seventeenth-century bridge over the Árakthos Potamós (river), Árta, Greece

Babelle and Marshall Druck—Photo Researchers/EB Inc

River north of the Gulf of Árta. The modern city stands on the site of Ambracia, an ancient Corinthian colony and the capital (from 294 BC) of Pyrrhus, king of Epirus. In 189 BC it was destroyed by the Romans. To commemorate his victory (31 BC) over Mark Antony at Actium, Octavian (later Augustus) founded the new town of Nicopolis Actia a few miles away; as a result, Ambracia declined.

Árta's modern history dates from the destruction of Nicopolis Actia in the 11th century AD by the Bulgars. A Byzantine bishopric, Árta survived a Norman seizure (1083) and the Greek despots of Epirus, passing in 1318 to the Orsini family of Cephalonia. It was captured by the Turks in 1449 but soon passed to Venice; after a brief period of French rule, it came again under the Turks. In the 16th and 17th centuries it was noted for its academic institutions. It was fought over several times during and after the War of Greek Independen-

dence (1821–29), but in 1881 it was ceded to Greece by Turkey.

The seat of a metropolitan bishop, Árta is a prosperous agricultural town surrounded by groves of orange, lemon, and citron trees. It also produces woolens, cottons, and embroidery. On the ancient acropolis are remains of a Byzantine fortress, and outside the town are several late 13th- and 14th-century churches and three 13th-century monasteries. Pop. (1991) city, 19,087; *nomós*, 78,719.

Árta, Gulf of, Modern Greek ΑΜΒΡΑΚΙΚΌΣ ΚΌΛΠΟΣ, deep inlet on the western coast of Greece. Almost landlocked by the peninsulas of Préveza on the north and Aktion on the south, it has access to the sea through the narrow Prévezis Strait. The northern shore of the gulf is formed by the combined deltas of the Louros and Arakthos rivers, with marshes and lagoons; the southern shore has broad bays alternating with wooded, rocky headlands. The town of Amfilokhia lies at the southeast corner of the gulf.

Artabanus, also called ARDABAN (d. 465/464 BC), minister of the Achaemenid king Xerxes I of Persia, whom he murdered in 465. According to one Greek source, Artabanus had previously killed Xerxes' son Darius and feared that the father would avenge him; other sources relate that he killed Xerxes first and then, pretending that Darius had done so, induced Darius' brother Artaxerxes I to avenge the "parricide." Artabanus was in control of the Achaemenid state for seven months and was recognized as king by Egypt. Finally, however, he was betrayed by his fellow conspirator Megabyzus and was killed by Artaxerxes.

Artabanus, also spelled ARDABAN, name of Parthian kings grouped below chronologically and indicated by the symbol ●.

● **Artabanus I**, also called ARSACES II (fl. 3rd and 2nd centuries BC), king of Parthia (reigned 211–191 BC) in southwestern Asia. In 209 he was attacked by the Seleucid king Antiochus III of Syria, who took Hecatompylos, the Ar-

Artabanus I, coin, late 3rd–early 2nd century BC; in the British Museum

By courtesy of the trustees of the British Museum, photograph, J R Freeman & Co Ltd

sacid capital (the present location of which is uncertain), and Syrinx in Hyrcania. Finally, however, Antiochus concluded a treaty with Artabanus, who after 206 lost much territory to Euthydemus, ruler of Bactria.

● **Artabanus III** (fl. 1st century AD), king of Parthia (reigned c. AD 12–c. 38).

At first king of Media Atropatene, Artabanus III took the Parthian throne in AD 9 or 10 from Vonones and was proclaimed king about two years later in Ctesiphon, the Parthian capital on the Tigris River. Vonones fled to Armenia, but Artabanus forced him to abdicate in AD 15 or 16. During the first part of Artabanus' reign there was peace with Rome. Although faced with internal unrest, he was apparently a strong king and helped restore the authority of the central government. A letter written by

Artabanus in December of 21 to the magistrates and the city of Susa is the only Arsacid royal document that has been preserved.

On the death of Artaxias III (Zeno) of Armenia (AD 34/35), Artabanus set his son, known only as Arsaces, on the Armenian throne. Two Parthian nobles, apparently restless at Artabanus' assertion of central authority, applied to the Roman emperor Tiberius for a king from among the descendants of an earlier king, Phraates IV. Thus, a grandson of Phraates, Tiridates III, arrived in Syria in AD 35 and was set on the Parthian throne by the Roman general Lucius Vitellius. Artabanus withdrew to Hyrcania, but within a year he was summoned by the anti-Roman party, returned, and won back his throne. The struggle had evidently weakened Parthia internally; large areas and some of the great commercial centres seem to have become independent of the crown. The general discontent drove Artabanus into flight again, and he took refuge with his vassal Izates II of Adiabene while a certain Cinnamus occupied the Parthian throne. Artabanus was restored by negotiation but died soon afterward.

● **Artabanus V** (fl. 3rd century), last king of the Parthian empire (reigned c. AD 213–224) in southwest Asia.

He was the younger son of Vologases IV, who died probably in 207, and was ruling the Median provinces at the time of his rebellion (c. 213) against his brother, Vologases V. By 216 he had apparently extended his power over the Mesopotamian part of the empire, although Vologases continued to strike coins at the Seleucia mint until 222 or 223. The Roman emperor Caracalla attacked Artabanus in 216, ravaging much of Media and desecrating the Parthian royal tombs at Arbela (modern 'Arbil, Iraq). In 217 Artabanus counterattacked; Caracalla was assassinated, and his successor, Macrinus, who was defeated at Nisibis (Nisibin), made peace with heavy indemnities. Meanwhile, however, Ardashir the Sāsānian, who had begun his rule as petty king in the province of Persis in 208, had been steadily extending his domains and winning Iranian allies against Parthian overlordship. Revolt became general, and Artabanus was finally killed in battle against Ardashir.

Artaud, Antonin (b. Sept. 4, 1896, Marseille, Fr.—d. March 4, 1948, Ivry-sur-Seine), French dramatist, poet, actor, and theoretician of the Surrealist movement who attempted to replace the "bourgeois" classical theatre with his "theatre of cruelty," a primitive ceremonial experience to liberate the human subconscious and reveal man to himself.

Artaud's parents were partly Levantine Greek, and he was much affected by this background, especially in his fascination with mysticism. Lifelong mental disorders sent him repeatedly into asylums. He sent his Surrealist poetry *L'Ombilic des limbes* (1925; "Umbilical Limbo") and *Le Pèse-nerfs* (1925; *Nerve Scales*) to the influential critic Jacques Rivière, thus beginning their long correspondence. After studying acting in Paris, he made his debut in Aurélien-Marie Lugné-Poe's Dadaist-Surrealist Théâtre de l'Oeuvre. Artaud broke with the Surrealists when their leader, the poet André Breton, gave their allegiance to communism. Artaud, who believed the movement's strength was extrapolitical, joined another defecting Surrealist, the dramatist Roger Vitrac, in the short-lived Théâtre Alfred Jarry. Artaud played Marat in Abel Gance's film *Napoléon* (1927) and appeared as a friar in Carl Dreyer's classic film *La Passion de Jeanne d'Arc* (1928).

Artaud's *Manifeste du théâtre de la cruauté* (1932; "Manifesto of the Theatre of Cruelty") and *Le Théâtre et son double* (1938; *The Theatre and Its Double*) call for a communion between actor and audience in a magic exorcism; gestures, sounds, unusual scenery, and

Artaud, 1948

Denise Colomb—J P Ziolo

lighting combine to form a language, superior to words, that can be used to subvert thought and logic and to shock the spectator into seeing the baseness of his world.

Artaud's own works, less important than his theories, were failures. *Les Cenci*, performed in Paris in 1935, was an experiment too bold for its time. His vision, however, was a major influence on the Absurd theatre of Jean Genet, Eugène Ionesco, Samuel Beckett, and others and on the entire movement away from the dominant role of language and rationalism in contemporary theatre. His other works include *D'un voyage au pays des Taramuharas* (1937; "A Voyage in the Land of the Taramuharas"), about his travels in Mexico, *Van Gogh, le suicidé de la société* (1947), and *Héliogabale, ou l'anarchiste couronné* (1934; "Heliogabalus, or the Crowned Anarchist").

Artavasdes II (fl. 1st century BC), king of Armenia (reigned 53–34 BC), the son and successor of Tigranes II the Great.

Artavasdes was at first an ally of Rome, but, when the Parthian king Orodes II invaded Armenia, he joined the Parthian side and gave his sister in marriage to Pacorus, Orodes' son. When the Romans under Mark Antony entered Armenia (36), Artavasdes again gave his allegiance to Rome. Later deserting the Roman forces, Artavasdes was captured by Antony when he reinvaded Armenia (34). Artavasdes was taken to Alexandria, where he was later killed by the Ptolemaic queen Cleopatra. Artavasdes was also an accomplished Greek scholar who composed dramas and other literary works.

Artaxerxes, Old Persian ARTAKHSHATHRA, name of Achaemenid kings, grouped below chronologically and indicated by the symbol ●.

● **Artaxerxes I** (d. 425 BC, Susa, Elam [now in Iran]), Achaemenid king of Persia (reigned 465–425 BC).

He was surnamed in Greek Macrocheir ("Longhand") and in Latin Longimanus. A younger son of Xerxes I and Amestris, he was raised to the throne by the commander of the guard, Artabanus, who had murdered Xerxes. A few months later, Artaxerxes slew Artabanus in a hand-to-hand fight. His reign, though generally peaceful, was disturbed by several insurrections, the first of which was the revolt of his brother the satrap of Bactria. More dangerous was the rebellion of Egypt under Inaros, who received assistance from the Athenians. Achaemenid rule in Egypt was restored by Megabyzus, satrap of Syria, after a prolonged struggle (460–454). In 448 fighting between the Achaemenids and the Athenians ended, and in the Samian and Peloponnesian wars Artaxerxes remained neutral; toward the Jews he pursued a tolerant policy. His building inscriptions at Persepolis record the completion of the throne hall of his father. The tomb of Artaxerxes is at Naqsh-e Rostam.

● **Artaxerxes II** (fl. late 5th and early 4th centuries BC), Achaemenid king of Persia (reigned 404–359/358).

He was the son and successor of Darius II and was surnamed (in Greek) Mnemon, meaning "the mindful." When Artaxerxes took the Persian throne, the power of Athens had been broken in the Peloponnesian War (431–404), and the Greek towns across the Aegean Sea in Ionia were again subjects of the Achaemenid Empire. In 404, however, Artaxerxes lost Egypt, and in the following year his brother Cyrus the Younger began preparations for his rebellion. Although Cyrus was defeated and killed at Cunaxa (401), the rebellion had dangerous repercussions, for it not only demonstrated the superiority of the Greek hoplites used by Cyrus but also led the Greeks to believe that Persia was vulnerable.

In 400 Sparta broke openly with the Achaemenids, and during the next five years its armies achieved considerable military success in Anatolia. The Spartan navy, however, was destroyed at Cnidus (394), thereby giving the Achaemenids mastery of the Aegean. The Greek allies of Persia (Thebes, Athens, Argos, and Corinth) continued the war against Sparta, but, when it became evident that the only ones to gain from the war were the Athenians, Artaxerxes decided to conclude peace with Sparta. In 386 Athens was compelled to accept the settlement known as the King's Peace, or the Peace of Antalcidas, by which Artaxerxes decreed that all the Asiatic mainland and Cyprus were his, that Lemnos, Imbros, and Scyros were to remain Athenian dependencies, and that all the other Greek states were to receive autonomy.

Elsewhere Artaxerxes met with less success. Two expeditions against Egypt (385–383 and 374) ended in complete failure, and during the same period there were continuous rebellions in Anatolia. There were also wars against the mountain tribes of Armenia and Iran.

By the King's Peace the Achaemenids had become the arbiters of Greece, and in the following wars all parties applied to them for a decision in their favour. After the Theban victory of Leuctra (371), an old alliance between the Achaemenids and the Thebans was restored. Achaemenid supremacy, however, was based on Greek internal discord rather than Achaemenid strength, and, when this weakness became apparent, all the satraps (governors) of Anatolia rose in revolt (c. 366), in alliance with Athens, Sparta, and Egypt, and Artaxerxes could do little against them. The satraps, however, were divided by mutual distrust, and the rebellion was finally put down by Persia through a series of treacheries. When the reign of Artaxerxes ended, Achaemenid authority had been restored over most of the empire—more from internal rivalries and discord than from his efforts.

Under Artaxerxes an important change occurred in the Persian religion. The Persians apparently did not worship images of the gods until Artaxerxes set up statues of the goddess Anāhitā in various large cities. Inscriptions by all former kings named only Ahura Mazda, but those of Artaxerxes also invoked Anāhitā and Mithra, two deities of the old popular Iranian religion that had been neglected.

• **Artaxerxes III** (d. 338 BC), Achaemenid king of Persia (reigned 359/358–338 BC).

He was the son and successor of Artaxerxes II and was called Ochus before he took the throne. Artaxerxes III was a cruel but energetic ruler. To secure his throne he put to death most of his relatives. In 356 he ordered all the satraps (governors) of the Achaemenid empire to dismiss their mercenaries. He also forced Athens to conclude peace and to acknowledge the independence of its rebellious allies (355).

Artaxerxes then attempted to subjugate Egypt, which had been independent since 404. Failure of the first attempt (351) encouraged the Phoenician towns and the princes of Cyprus to revolt. Early in 345, Artaxerxes collected a great army and marched against the

Phoenician city of Sidon. Mentor of Rhodes, who had helped betray Sidon, rose high in the king's favour and entered into a close understanding with the eunuch Bagoas, the king's favourite. Artaxerxes then advanced on Egypt with a great land and naval force and, at Pelusium in the Nile River delta, defeated the pharaoh Nectanebo II (343). A Persian satrap was placed over Egypt, the walls of its cities were destroyed, its temples were plundered, and Artaxerxes was said to have killed the Apis bull with his own hand.

After the king's return to Susa, Bagoas ruled the court and the upper satrapies, while Mentor restored the authority of the empire throughout the west. When Philip of Macedonia attacked Perinthus and Byzantium (340), Artaxerxes sent support to those cities. In 338 Artaxerxes and his elder sons were killed by Bagoas, who then raised the king's youngest son, Arses, to the throne.

Artaxias, also spelled ARTASHES (fl. 2nd century BC) one of the founders of the ancient kingdom of Armenia (reigned 190–159 BC).

After the defeat of the Seleucid king Antiochus III the Great by the Romans in the Battle of Magnesia (190), Artaxias and Zariadres, who were Antiochus' satraps (governors) in Armenia, revolted and established themselves with Roman consent as kings of Greater Armenia and its district of Sophene to the southwest, respectively. They united their efforts to enlarge their domains at the expense of neighbouring areas and are considered the creators of historical Armenia. Artaxias built his capital, Artaxata, on the Araxes (now Aras, or Araks) River near Lake Sevan.

Artemidorus (fl. 100 BC, Ephesus, Lydia [now in Turkey]), Greek geographer whose systematic geography in 11 books was much used by the famed Greek geographer-historian Strabo (b. 64/63 BC). Artemidorus' work is based on his itineraries in the Mediterranean and on the records of others. The work is known only from Strabo's references to it and from fragments preserved by later authors and from the surviving part of an abridgment, dating possibly from the early 5th century AD, of his coastal guide to the Mediterranean and Euxine (Black) seas.

Artemidorus Daldianus (fl. 2nd century AD, Ephesus, Roman Asia [now in Turkey]), soothsayer whose *Oneirocritica* ("Interpretation of Dreams") affords valuable insight into ancient superstitions, myths, and religious rites. Mainly a compilation of the writings of earlier authors, the work's first three books consider dreams and divination generally; a reply to critics and an appendix make up the fourth book.

Artemis, in Greek religion, the goddess of wild animals, the hunt, and vegetation, and of chastity and childbirth; she was identified by the Romans with Diana (*q.v.*). Artemis was the daughter of Zeus and Leto and the twin sister of Apollo. Among the rural populace, Artemis was the favourite goddess. Her character and function varied greatly from place to place, but, apparently, behind all forms lay the goddess of wild nature, who danced, usually accompanied by nymphs, in mountains, forests, and marshes. Artemis embodied the sportsman's ideal, so besides killing game she also protected it, especially the young; this was the Homeric significance of the title Mistress of Animals.

The worship of Artemis probably flourished in Crete or on the Greek mainland in pre-Hellenic times. Many of Artemis' local cults, however, preserved traces of other deities, often with Greek names, suggesting that, upon adopting her, the Greeks identified Artemis with nature divinities of their own.

While the mythological roles of other prominent Olympians evolved in the works of the poets, the lore of Artemis developed primar-

ily from cult. Dances of maidens representing tree nymphs (dryads) were especially common in Artemis' worship as goddess of the tree cult, a role especially popular in the Peloponnese. Throughout the Peloponnese, bearing such epithets as Limnaea and Limnatis (Lady of the Lake), Artemis supervised waters and lush wild growth, attended by nymphs of wells and springs (naiads). In parts of the peninsula her dances were wild and lascivious.

Artemis as a huntress, classical sculpture; in the Louvre

Alinari—Art Resource/EB Inc

Outside the Peloponnese, Artemis' most familiar form was as Mistress of Animals. Poets and artists usually pictured her with the stag or hunting dog, but the cults showed considerable variety. For instance, the Tauropolia festival at Halae Araphenides in Attica honoured Artemis Tauropolos (Bull Goddess), who received a few drops of blood drawn by sword from a man's neck.

The frequent stories of the love affairs of Artemis' nymphs are supposed by some to have originally been told of the goddess herself. The poets after Homer, however, stressed Artemis' chastity and her delight in the hunt, dancing and music, shadowy groves, and the cities of just men. The wrath of Artemis was proverbial, for to it myth attributed wild nature's hostility to humans. Yet Greek sculpture avoided Artemis' unpitiful anger as a motif; in fact, the goddess herself did not become popular as a subject in the great sculptural schools until the relatively gentle 4th-century-BC spirit prevailed.

Artemis, Temple of, at Ephesus, one of the Seven Wonders of the World. The great temple was built by Croesus, king of Lydia, in about 550 BC and was rebuilt after being burned by a madman named Herostratus in 356 BC. The Artemesium was famous not only for its great size (over 350 by 180 feet [about 110 by 55 m]) but also for the magnificent works of art that adorned it. The temple was destroyed by invading Goths in AD 262 and was never rebuilt. Little remains of the temple (though there are many fragments, especially of sculptured columns, in the British Museum), but excavation has revealed traces of both Croesus' and the 4th-century temple and of three earlier, smaller ones.

Copies survive of the famous statue of Artemis, an un-Greek representation of a mummylike goddess, standing stiffly straight,

with her hands extended outward. The original statue was made of gold, ebony, silver, and black stone, the legs and hips covered by a garment decorated with reliefs of animals and

of Caria, in southwestern Anatolia, and sole ruler for about three years after the king's death. She built for her husband, in his capital at Halicarnassus (modern Bodrum, Turkey), the tomb called the Mausoleum, which was considered one of the Seven Wonders of the World. Artemisia was also known as a botanist

one or more coronary arteries can cause the death of a section of the heart muscle (myocardial infarction). Treatments for coronary artery disease include coronary bypass surgery and balloon angioplasty (the dilation of an artery and flattening of its plaque deposits by means of a balloon catheter).

Arteriosclerosis affecting the cerebral blood vessels may interfere with blood flow to the brain and result in a stroke, a loss of consciousness followed by some degree of paralysis. Treatment directed at prevention of such strokes includes administration of drugs that reduce the blood pressure and those that thin blood serum or decrease platelets, inhibiting the ability of blood to clot. Arteriosclerosis affecting the peripheral arteries may reduce blood flow to the legs and cause intermittent lameness and ulceration. There is also an increased possibility of infection in the feet and legs.

arteriovenous fistula, abnormal direct opening between an artery and a vein; it sometimes results from accidental penetration wounds or from vascular disease, or it may be congenital in origin. As a result of the defect, the arterial pressure is passed to the venous side of the fistula, and the pressure in the vein in the side of the fistula away from the heart increases, causing distension.

Affected persons complain of aching pain in or beyond the area of the injury, and the legs are usually puffy and frequently show distended veins. When there is an arteriovenous fistula, the pulse in the vein is diminished by direct compression of the supplying artery, resulting in a continuous murmur that may help in diagnosing and locating the fistula. By surgical repair normal flow can usually be reestablished.

arteritis, inflammation of the arteries. It may occur in any of a number of diseases, including syphilis; tuberculosis; disease of the pancreas; serum sickness, which is a reaction against a foreign protein; and lupus erythematosus, a systemic disease that has also been attributed to some form of immune reaction. Five varieties of arteritis not closely associated with systemic disease or disease of an organ outside the cardiovascular system have been described: thromboangiitis obliterans (see Buerger's disease); temporal, or cranial, arteritis; arteritis of the aged—also called senile arteritis and polymyalgia rheumatica; aortic arch arteritis (see aortic arch syndrome); and polyarteritis nodosa (*q.v.*).

Temporal, or cranial, arteritis (also known as giant-cell arteritis), which involves inflammation of the temporal arteries and of other arteries in the cranial area, is of unknown cause, although it is usually preceded by an infection. Most persons affected are in their 50s or older. The disease usually starts with a headache, which may be accompanied by pain in the scalp, face, jaws, and eyes. The affected person may find it difficult to move his jaws because of deficiency of blood flow to the jaw muscles. Paralysis of the eye muscles—ophthalmoplegia—may cause the affected person to see double, a condition called diplopia. Fluid may collect in the retina and in the optic disk, the point at which the optic nerve enters the eyeball; this condition leads to vision loss in about 10 percent of those diagnosed. The disease may persist for as long as three years or may subside in a few months. The chief danger of temporal arteritis is its effect upon the eyes. Impairment of vision is combated by administration of an adrenocorticosteroid hormone (a hormone secreted by the adrenal gland or a synthetic substitute).

The more common arteritis of the aged, which may be related to temporal arteritis, characteristically causes pain and wasting in the upper muscles of the limbs and in certain muscles of the neck. The condition usually develops rapidly, often after sensations of fa-

Reconstruction of the west front of the Temple of Artemis at Ephesus, first built c. 550 BC, drawing by Bluma Trell and Stuart Shaw; in the Metropolitan Museum of Art, New York City

bees and the top of the body festooned with breasts; her head was adorned with a high-pillared headdress.

Artemisa, city, western La Habana *provincia*, western Cuba, situated east of the Sierra del Rosario. Artemisa is a key commercial and processing centre of the region. Sugarcane, tobacco, and pineapples and other fruits are its major agricultural products. Liquor and soap are made in the city, and sugar refineries are nearby. Artemisa lies on the main highway and main railroad line between Havana and Pinar del Río. Pop. (1990 est.) 52,618.

Artemisia I (fl. first half of 5th century BC), queen of Halicarnassus, a Greek city in Caria, and of the nearby island of Cos in about 480.

Artemisia ruled under the overlordship of the Persian king Xerxes (reigned 486–465) and participated in Xerxes' invasion of Greece (480–479). Despite her able command of five ships in the major naval battle with the Greeks off the island of Salamis near Athens, the Persian fleet suffered a severe defeat. Herodotus claims that Xerxes acted on her advice when he decided to retreat from Greece at once rather than to risk another engagement.

Artemisia II (d. c. 350 BC), sister and wife of King Mausolus (reigned 377/376–353/352)

and medical researcher; *Artemisia*, a plant genus, is named after her.

Artemisium, Battle of (480 BC), during the Greco-Persian Wars, a Persian naval victory over the Greeks in an engagement fought near Artemisium, a promontory on the north coast of Euboea. The Greek fleet held its own against the Persians in three days of fighting but withdrew southward when news came of the defeat at Thermopylae.

Artemivsk, Russian ARTYOMOVSK, ART'OMOVSK, or ARTEMOVSK, formerly (until 1924) BAKHMUT, city, Donetsk *oblast* (province), eastern Ukraine, on the Bakhmut River. The town originated in the 17th century as a fort protecting the Russian frontiers against the Crimean Tatars. Peter I the Great established a salt industry there in 1701, but seven years later the fort was destroyed in the Bulavin revolt. It officially became a town in 1783. Salt operations were revived in the 19th century and are now the largest in Ukraine; they gave rise to a chemical industry based similarly on local supplies of limestone and coke. There are also metalworking and light industries. Cultural amenities include an institute of the salt industry, various technical colleges, and medical, teacher-training, and music schools. Pop. (1991 est.) 90,800.

arteriosclerosis, also called HARDENING OF THE ARTERIES, chronic disease characterized by abnormal thickening and hardening of the walls of arteries, with a resulting loss of elasticity. The major form of arteriosclerosis is atherosclerosis, in which plaques of fatty deposits, or atheromas, form on the inner walls of the arteries.

In atherosclerosis, cholesterol-carrying lipoproteins in the circulating blood are gradually deposited on the inner linings of arteries over a period of years. As more cholesterol is deposited on the lining, initially tiny lesions enlarge and thicken to form plaques, narrowing the vessel channel and interfering with the flow of blood through it. The formation of fatty deposits may also be accompanied by scar tissue and calcification, which make the vessel walls less elastic, one consequence being an increase in blood pressure. Eventually an arterial channel may be completely blocked by thick plaques, or a blood clot (thrombus) may form at the site of a plaque and likewise obstruct the channel.

When atherosclerosis affects the coronary arteries, which bring oxygen-rich blood to the heart muscle, it can decrease the supply of blood to the heart muscle and result in the pain of angina pectoris. The complete occlusion of

Anderson—Alinari from Art Resource

tigue and loss of appetite. Adrenal steroids moderate the symptoms, but usually recovery occurs whether or not this medication is used.

artery, in human physiology, any of the vessels that, with one exception, carry oxygenated blood and nourishment from the heart to the tissues of the body. The exception, the pulmonary artery, carries oxygen-depleted blood to the lungs for oxygenation and removal of excess carbon dioxide (see pulmonary circulation).

Arteries are muscular and elastic tubes that must transport blood under a high pressure exerted by the pumping action of the heart. The pulse, which can be felt over an artery lying near the surface of the skin, results from the alternate expansion and contraction of the arterial wall as the beating heart forces blood into the arterial system via the aorta. Large arteries branch off from the aorta and in turn give rise to smaller arteries until the level of the smallest arteries, or arterioles, is reached. The threadlike arterioles carry blood to networks of microscopic vessels called capillaries, which supply nourishment and oxygen to the tissues and carry away carbon dioxide and other products of metabolism by way of the veins.

The largest artery is the aorta, which arises from the left ventricle of the heart. The aorta arches briefly upward before continuing downward close to the backbone; the arteries that supply blood to the head, neck, and arms arise from this arch and travel upward. As it descends along the backbone, the aorta gives rise to other major arteries that supply the internal organs of the thorax. After descending to the abdomen, the aorta divides into two terminal branches, each of which supplies blood to one leg.

Each artery, no matter what its size, has walls with three layers, or coats. The innermost layer, or tunica intima, consists of a lining, a fine network of connective tissue, and a layer of elastic fibres bound together in a membrane pierced with many openings. The tunica media, or middle coat, is made up principally of smooth (involuntary) muscle cells and elastic fibres arranged in roughly spiral layers. The outermost coat, or tunica adventitia, is a tough layer consisting mainly of collagen fibres that act as a supportive element. The large arteries differ structurally from the medium-sized arteries in that they have a much thicker tunica media and a somewhat thicker tunica adventitia. See also cardiovascular system.

Artesia, city, Eddy county, southeastern New Mexico, U.S., near the Pecos River. It originated in 1890 as a stop (called Miller) on the old stagecoach route between Roswell and Carlsbad. As a livestock-shipping point on the Pecos Valley Southern Railway (completed 1894), it was known as Stegman. It adopted its present name in 1905 following the discovery of an underground artesian water basin.

Artesia is a trade centre and shipping point for the surrounding irrigated farmlands (wool, cotton, alfalfa, feeds) and ranchlands. Nearby oil and gas fields (discovered in 1923) support refineries, extraction plants, and petrochemical industries. Potash mining is also of economic importance in the area. The first underground school (Abo Elementary) in the United States, designed for safety against atomic radiation and fallout, was built within the city. Inc. village, 1905; city, 1930. Pop. (1992 est.) 11,071.

artesian well, a man-made spring from which water flows under natural pressure without

pumping. It is dug or drilled wherever a gently dipping, permeable rock layer (such as sandstone) receives water along its outcrop at a level higher than the level of the surface of the ground at the well site. At the outcrop the water moves down into the aquifer (water-bearing layer) but is prevented from leaving it by impermeable rock layers (such as shale) above and below it. Pressure from the water's weight (hydrostatic pressure) forces water to the surface of a well drilled down into the aquifer; the pressure for the steady upflow is maintained by the continuing penetration of water into the aquifer at the intake area.

In places where the overlying impermeable rocks are broken by joints or faults, water may escape through them to rise to the surface as artesian springs. In some areas, artesian wells and springs are a major source of water, especially in arid plains adjacent to mountain ranges that receive precipitation. The rapid development of new wells through overdrilling, however, has tended to reduce head pressures in many artesian systems. As a result, most artesian wells are now outfitted with pumps.

Artevelde, Jacob van, English JAMES VAN ARTEVELDE (b. c. 1295, Ghent, Flanders [now in Belgium]—d. July 17, 1345, Ghent), Flemish leader who played a leading role in the preliminary phase of the Hundred Years' War (1337–1453). Governing Ghent with other "captains" from 1338, he aligned the Flemings with King Edward III of England and against both France and the Count of Flanders. He maintained his position as chief captain until he was murdered in a riot seven years later.

Van Artevelde's profession is unknown, but he belonged to the wealthy bourgeoisie and owned land both in Ghent and in the surrounding area. He was twice married, the second time to Kateline de Coster, whose family had considerable influence in Ghent. Van Artevelde had already reached middle age when he began to take part in public affairs. The only mention of him before 1338 is as a supporter of Louis I, Count of Flanders, during a revolt against Louis in Ghent in 1325. But as relations between England and France worsened in the 1330s, tension arose between the count and the Flemish towns. Louis, a vassal of the French king Philip VI, sided with France. The towns, although Philip offered them inducements, needed English wool for their weaving industry and could not afford to alienate Edward III of England.

At that point, van Artevelde emerged as a leader. In 1338, at a great meeting at the Monastery of Biloke, he unfolded his plan for an alliance of the Flemish towns with those of Brabant, Holland, and Hainaut to maintain an armed neutrality in the dynastic struggle between France and England. His efforts were successful. Early in 1338, the people of Ghent, under his leadership, declared their neutrality, and the major towns of Bruges and Ypres followed suit, joining together in a league for that purpose. France was forced to acquiesce, and the vital wool trade with England was safeguarded.

In Ghent itself van Artevelde, with the title of captain general, henceforth exercised almost dictatorial authority until his death. His first step was to bring about the conclusion of a commercial treaty with England. The Count of Flanders tried to overthrow van Artevelde's power by force of arms but failed completely and was compelled at Bruges to sign a treaty (June 21, 1338) sanctioning the federation of Ghent, Bruges, and Ypres. This was followed during the year 1339–40 by more treaties that gradually brought into the federation many of the towns and provinces of the Netherlands. The policy of neutrality, however, proved impracticable, and the Flemish towns, under van Artevelde, openly took the side of the English, with whom a close alliance was concluded (Jan. 26, 1340). Van Artevelde now reached

the height of his power, concluding alliances with kings and publicly associating with them on equal terms. Under his able administration, trade flourished and Ghent rose rapidly in wealth and importance.

Van Artevelde's virtually despotic rule eventually provoked his compatriots to jealousy and resentment. His proposal to disown the sovereignty of the Count of Flanders and to recognize in its place that of Edward III's eldest son, Edward the Black Prince, gave rise to violent dissatisfaction. In 1345 a popular insurrection broke out in Ghent, and van Artevelde fell into the hands of the crowd and was murdered. One of his sons, Philip (b. 1340), eventually led an unsuccessful revolt against Count Louis II of Flanders in 1382. Jacob van Artevelde's memory was resurrected by Belgian-nationalist historians in the 19th century as an early hero in the country's long struggle for independence.

BIBLIOGRAPHY. Studies of his life and influence include Henry Stephen Lucas, *The Low Countries and the Hundred Years' War, 1326–1347* (1929, reprinted 1976), an analytic description of van Artevelde's part in the Hundred Years' War in its first stage; and David Nicholas, *The van Arteveldes of Ghent* (1988), discussing Jacob and his son Philip.

artha (Sanskrit: "wealth," or "property"), in Hinduism, the pursuit of wealth or material advantage, one of the four traditional aims in life. The sanction for *artha* rests on the assumption that—with the exclusion of the exceptional few who can proceed directly to the final aim of moksha, or spiritual release from life—material well-being is a basic necessity of man and is his appropriate pursuit while a householder, that is, during the second of the four life stages. Furthermore, *artha*, as the pursuit of material advantage, is closely tied to the activities of statecraft, which maintains the general social order and prevents anarchy. But, as the immoderate pursuit of material advantage would lead to undesirable and ruinous excesses, *artha* must always be regulated by the superior aim of dharma, or righteousness.

Artha-śāstra (Sanskrit: "Handbook of [the King's] Profit"), singularly important Indian manual on the art of politics, attributed to Kauṭilya (also known as Viṣṇugupta or Cāṅkya), who reportedly was chief minister to King Candragupta (c. 300 BC), the founder of the Maurya dynasty. Although it is unlikely that all of the text dates to such an early period, several parts have been traced back to the Mauryas.

The author of the *Artha-śāstra* is concerned with central control by the king of a realm of fairly limited size, and he speaks of the way the state's economy is organized, how ministers should be chosen and war conducted, and how taxation should be arranged and distributed. Great emphasis is placed on the importance of a network of runners, informers, and spies, which, in the absence of a ministry of public information and a police force, functioned as a surveillance corps for the king, focusing particularly on any external threats and internal dissidence.

Entirely practical in purpose, the *Artha-śāstra* presents no overt philosophy. But implicit is a complete skepticism, if not cynicism, concerning human nature and its corruptibility and the ways in which the king—and his trusted servant—can take advantage of such human weakness.

Unstated but apparent is the paradox that a king has to have complete confidence in the minister who is ruling his state. This paradox was dramatized by the playwright Viśākha-datta (c. 5th century AD), who was probably at the court of the Guptas, in his Sanskrit

play *Mudrārākṣasa* ("Minister Rākṣasa and His Signet Ring").

arthāpatti (Sanskrit: "the incidence of a case"), in Indian philosophy, the fifth of the five means of knowledge (*pramāṇa*) by which man obtains accurate knowledge of the world. *Arthāpatti* is knowledge arrived at by circumstantial implication. See *pramāṇa*.

arthritis, inflammation of the joints and its effects. In its acute form, arthritis is marked by pain, inflammation, redness, and swelling. There are three principal forms; see osteoarthritis; rheumatoid arthritis; septic arthritis.

arthrodire, any member of an order of extinct, armoured, jawed fishes, class Placodermi, found in Devonian freshwater and marine deposits. (The Devonian period lasted from 408 million to 360 million years ago.) Early arthrodires, such as the genus *Arctolepis*, were well-armoured fishes with flattened bodies. They had hollow, backward-curved shoulder spines and may have used the long spines to anchor themselves or to move about on the bottom.

Later arthrodires, such as the Middle Devonian genus *Coccosteus*, tended toward marine habitats. Coccosteans were less heavily armoured than *Arctolepis*, and the bony head and body shields were connected by a joint on each side allowing free head movement. They were predators and had bony jaws with tusklike projections in front and cutting edges in back. The back of the body and the tail apparently were naked. The shoulder spine was shortened or, in some forms, absent.

Arthrodires became extinct during the Late Devonian. The genus *Dinichthys* (sometimes included with *Dunkleosteus*), representative of this period, was similar to coccosteans but grew much longer, about 9 m (30 feet) against 0.6 m (2 feet) for coccosteans.

There were many arthrodire offshoots during the Devonian. Members of the genus *Phyllolepis* were specialized fishes that had lost most of the head armour. They were formerly considered ostracoderms. The ptyctodonts, relatives of the arthrodires, lived in the sea and possibly fed upon mollusks. Ptyctodonts have been thought of as ancestors of chimaeras, but evidence is inconclusive.

arthropod, any member of the phylum Arthropoda, the largest such division in the animal kingdom, consisting of at least 1,000,000 invertebrate species.

A brief treatment of arthropods follows. For full treatment, see MACROPAEDIA: Arthropods.

Arthropoda is the largest animal phylum and is one of tremendous diversity. By far the largest group within the phylum comprises the insects, one class of the subphylum Uniramia. The remaining three subphyla are Chelicerata (e.g., spiders, scorpions, ticks, and mites), Crustacea (shrimp, crabs, lobsters, crayfish, sand fleas), and Trilobita, an early group of arthropods that became extinct during the Permian period (286 million to 245 million years ago).

All arthropods are bilaterally symmetrical and possess a segmented body in which each segment may bear a pair of limbs. The most characteristic feature of the arthropods is a covering (exoskeleton) that, when thickened, forms an articulated armour over body and limbs and provides a surface area for muscle attachment. The head carries a dorsal brain, sense organs, and the feeding apparatus. Among the several classes a variable number of trunk segments have been incorporated into the head, the head structure alone serving to differentiate the groups. Terrestrial arthropods possess tracheal tubes or book lungs, or both, as respiratory organs; aquatic arthropods possess gills. The exoskeleton is periodically

molted to allow growth. Some arthropods, especially crustaceans, are able to regenerate missing limbs.

Arthropods exhibit every type of feeding mode. They are carnivores, herbivores, detritus feeders, filter feeders, and parasites. Each arthropod group has specialized the paired appendages around the mouth in accordance with the particular diet.

With few exceptions, the sexes of arthropods are separate. Sperm are commonly transferred to the female within sealed packets called spermatophores. Some arthropods (especially arachnids) exhibit courtship behaviour prior to fertilization. Crustaceans usually go through a larval stage upon hatching, while most young chelicerates and insects resemble the adult.

Arthropods have successfully adapted to nearly all environments, both aquatic and terrestrial. A species of jumping spider, for example, is able to live permanently at latitudes above 6,000 m (19,680 feet) on the upper slopes of Mount Everest. In contrast, a certain kind of blind crab thrives at depths of 2,500 m (8,200 feet) in the Galapagos Rift several hundred miles off the coast of Ecuador.

Arthur, name of rulers grouped below by country and indicated by the symbol ●.

BRITAIN

● **Arthur**, legendary British king who appears in a cycle of medieval romances (known as the matter of Britain) as the sovereign of a knightly fellowship of the Round Table (*q.v.*). It is not certain how or where (in Wales or in those parts of northern Britain inhabited by Brythonic-speaking Celts) these legends origi-

King Arthur, detail from "Christian Heroes," a French wool tapestry attributed to Nicolas Bataille, late 14th century; in the Cloisters, Metropolitan Museum of Art, New York City

nated or whether the figure Arthur was based on a historical person. See also Arthurian legend.

Assumptions that a historical Arthur led Welsh resistance to the West Saxon advance from the middle Thames are based on a conflation of two early chroniclers, Gildas and Nennius, and on the *Annales Cambriae* of the late 10th century. The 9th-century *Historia Britonum* of Nennius records 12 battles fought by Arthur against the Saxons, culminating in a victory at Mons Badonicus. The Arthurian section of this work, however, is from an undetermined source, possibly a poetic text. The *Annales Cambriae* also mention Arthur's victory at Mons Badonicus (516) and record the Battle of Camlann (537), "in which Arthur

and Medraut fell." Gildas' *De excidio et conquestu Britanniae* (mid-6th century) implies that Mons Badonicus was fought in about 500 but does not connect it with Arthur.

Another speculative view, put forward by R.G. Collingwood (*Roman Britain and the English Settlements*, 1936), is that Arthur was a professional soldier, serving the British kings and commanding a cavalry force trained on Roman lines, which he switched from place to place to meet the Saxon threat.

Early Welsh literature, however, quickly made Arthur into a king of wonders and marvels. The 12th-century prose romance *Kulhwch and Olwen* associated him with other heroes, this conception of a heroic band, with Arthur at its head, doubtless leading to the idea of Arthur's court.

BRITTANY

● **Arthur I** (b. March 29, 1187, Nantes, Brittany—d. April 3, 1203?, Rouen or Cherbourg), duke of Brittany, a grandson of King Henry II of England; he was a rival of his uncle John (king of England from 1199) for several French provinces, both in his own interest and in that of King Philip II Augustus of France.

In October 1190 Arthur was recognized as heir presumptive to the English throne by another uncle, the childless King Richard I the Lion-Heart. Arthur was a posthumous child of Geoffrey, fourth of Henry II's five sons, and his wardship was a point of contention between Richard and Philip. From 1196 he was reared in Philip's household, causing Richard to disinherit the boy in favour of John, who, after Richard's sudden death, was accepted as king in England and Normandy. Philip, however, recognized Arthur's right to Brittany, Anjou, Aquitaine, and Maine and betrothed his daughter Mary to the young duke. The situation was complicated by Eleanor of Aquitaine, widow of Henry II, who wanted Aquitaine and Anjou for John. Captured in battle by John at Mirebeau-en-Poitou on Aug. 1, 1202, Arthur was imprisoned and, according to tradition, was murdered either by John himself or at his order.

● **Arthur II** (b. 1262—d. 1312, Château de l'Isle, near La Roche-Bernard, Brittany), duke of Brittany (1305–12), son of John II and Beatrice of England.

By successive marriages before his accession, he acquired the viscounty of Limoges (1275) and the county of Montfort-l'Amaury (1292). During his short reign, the war between Edward I of England and Philip IV of France was ended by treaty, whereby France ceded Brittany to England; but Arthur, with the vigorous support of the Bretons, defied and aborted the transfer. Arthur was succeeded by his son, John III the Good.

● **Arthur III**: see Richemont, Arthur, constable de.

Arthur, village on the Douglas-Moultrie county line, east-central Illinois, U.S. Founded in 1872 as a farming centre, it was originally called Glasgow and later renamed for the brother of Robert Hervey, president of the Paris and Decatur Railroad. Members of the Old Order Amish settlement, a conservative religious group in the area since 1865, have contributed to the character of the community. Horse-drawn buggies, the mode of travel for many Amish, share the country roads and village streets with automobiles. Agriculture (grain and livestock) is the mainstay of the economy, supplemented by some light industry, including a broomcorn-processing plant. Inc. 1877. Pop. (1990) 2,112.

Arthur, Chester A(Ian) (b. Oct. 5, 1829, North Fairfield, Vt., U.S.—d. Nov. 18, 1886, New York City), 21st president of the United States (1881–85). Elected vice president on the Republican ticket of 1880, he acceded to the

presidency on the assassination of President James A. Garfield.

Arthur graduated from Union College, Schenectady, N.Y., in 1848. He then taught school

while studying law, and in 1853 he entered a law office in New York City. Admitted to the New York bar in 1854. Arthur was an ardent abolitionist and won an early reputation by successfully pleading the case of a slave who sued for his freedom on the ground that his master had brought him temporarily to the free state of New York. Joining the Republican Party in the 1850s, Arthur became active in local politics and was quartermaster general of New York state's troops during the Civil War.

Resuming his law practice in 1863, he became closely associated with New York Republican boss Senator Roscoe Conkling, and in 1871 he was appointed customs collector for the port of New York City by President Ulysses S. Grant. The customhouse had long been conspicuous for some of the most flagrant abuses of the spoils system, and, although Arthur conducted the business of the office with integrity, he continued the practice of overstaffing it with employees whose chief qualification was loyalty to Conkling. In 1877 the newly elected president Rutherford B. Hayes, intent on reform of the civil service, demanded the resignation of Arthur and others in the New York City customhouse. With the support of Conkling, Arthur was able to resist Hayes for a time; but in July 1878 Hayes finally suspended him, and once again Arthur returned to the practice of law.

As a delegate to the Republican National Convention of 1880, Arthur worked with Conkling and the "Stalwart" faction for the renomination of Grant for a third term as president. With the triumph of James A. Garfield, Arthur was offered the vice presidency as a conciliatory gesture to the Stalwarts. His nomination was coldly received by the public, however, and when, during his first few months in office, he openly sided with Conkling in a bitter conflict with Garfield over New York patronage, the impression was widespread that he was too partisan for the nation's second highest office.

Acceding to the presidency on Sept. 19, 1881, in a period of intense factional controversy, Arthur is said to have been deeply wounded by public apprehension over the prospect of an administration in the hands of so confirmed an adherent of the spoils system. He did replace six of the seven members of Garfield's cabinet with his own appointees, but his appointments were generally unexceptionable, and he displayed an unexpected independence by his veto in 1882 of an \$18,000,000 rivers and harbours bill that contained ample funds for projects that could be used for political patronage. He particularly confounded his critics and dismayed his friends among the Stalwarts by his support of the Pendleton Act (1883), which created a federal civil-service system (with appointments and promotions

based on merit) applying to a limited number of specified offices. He and his secretary of the navy, William E. Chandler, recommended the appropriations that initiated the rebuilding of the U.S. Navy toward the strength it later achieved at the time of the war with Spain.

In 1884 Arthur, who was secretly suffering from Bright's disease, an incurable kidney ailment, allowed his name to be presented for the Republican presidential nomination. Defeated by James G. Blaine, he retired to New York City at the end of his term.

BIBLIOGRAPHY. Studies of his life and politics include George Frederick Howe, *Chester A. Arthur* (1934, reissued 1987); Thomas C. Reeves, *Gentleman Boss: The Life of Chester Alan Arthur* (1975); and Justus D. Doenecke, *The Presidencies of James A. Garfield & Chester A. Arthur* (1981).

Arthur, Sir George, 1ST BARONET (b. June 21, 1784, Plymouth, Devon, Eng.—d. Sept. 19, 1854, London), colonial administrator who was governor of Van Diemen's Land (now Tasmania) from 1825 to 1836. His efforts to expand the island's economy were remarkably successful.

After army duty in the Napoleonic Wars in Europe and Egypt (1804–14), Arthur served as lieutenant governor of British Honduras (1814–22). He was named lieutenant governor of Van Diemen's Land in 1823 and became governor two years later, when the colony was separated from New South Wales. That year (1825) he also helped the Van Diemen's Land Company to develop the northwest area of the island. He campaigned effectively against the bushrangers, rural outlaws who had robbed the settlers and fought the Aborigines. His attempt to restrict the Aboriginal population to the southeastern peninsula behind the so-called Black Line of armed settlers was a complete failure (see Black War). By 1835 the remaining Aborigines were persuaded to settle northeast of Tasmania on Flinders Island, where they soon died out.

Arthur established a penal settlement at Port Arthur (1832) and a model prison for boys at Point Puer (1835). He also helped to develop the colony's religious life and education. He antagonized the Tasmanian and Sydney press, however, by his autocratic administration and by his attempts at censorship.

In 1837 Arthur was appointed lieutenant governor of Upper Canada (now Ontario), arriving just after a rebellion against British rule had been suppressed. He was rewarded with a baronetcy for his help in uniting Upper Canada and Lower Canada (now Quebec) in 1841 and in 1842 was named governor of Bombay. He retired to England in 1846.

Arthur, J.C., in full JOSEPH CHARLES ARTHUR (b. Jan. 11, 1850, Lowville, N.Y., U.S.—d. April 30, 1942, Lafayette, Ind.), American botanist who discovered basic facts about the parasitic fungi known as rusts.

Graduated from what is now Iowa State University, Ames, in 1872, Arthur received his doctorate at Cornell University, Ithaca, N.Y., in 1886. In 1887 he became professor of botany at Purdue University, West Lafayette, Ind., where he served until 1915. During his professorship at Purdue he was also a professor in the Indiana Agricultural Experiment Station, and it was during this period that he made his chief contributions on the life history of rusts. From 1882 to 1900 he was an editor of the *Botanical Gazette*.

Arthur wrote many articles on botanical subjects and published a *Handbook of Plant Dissection*, with Charles R. Barnes and John M. Coulter (1886), *Living Plants and Their Properties*, with Daniel T. MacDougal (1898), and *Manual of the Rusts in United States and Canada* (1934).

Arthur, Jean, original name GLADYS GEORGIANNA GREENE (b. Oct. 17, 1905, New York, N.Y., U.S.—d. June 19, 1991, Carmel, Calif.),

American film actress known for her cracked, throaty voice, which accentuated her witty charm and intelligence in several comedies.

After modeling and performing in small parts on the Broadway stage, Arthur made her screen debut in a silent western, *Cameo Kirby* (1923). She found her niche as a comedienne in the wacky film *The Whole Town's Talking* (1935). Her screen persona as a no-nonsense,

Jean Arthur
Culver Pictures

emotionally honest heroine proved to have wide appeal, and she starred in such Frank Capra social comedies as *Mr. Deeds Goes to Town* (1936), *You Can't Take It with You* (1938), and *Mr. Smith Goes to Washington* (1939), as well as in such hits as *Only Angels Have Wings* (1939), *The Talk of the Town* (1942), and *The More the Merrier* (1943), which earned her an Academy Award nomination for best actress.

When her movie contract expired in 1944, Arthur, who had a chronic case of camera jitters, gladly retired from film. She was lured back to Hollywood to star, with Marlene Dietrich, in a comedy of postwar Berlin, *Foreign Affair* (1948), and in the western classic *Shane* (1953). She portrayed a lawyer in her own television series, *The Jean Arthur Show*, in 1966 and made occasional appearances on Broadway during the 1970s before retiring completely from show business. She later taught drama at Vassar College, Poughkeepsie, N.Y., and other schools.

Arthur Kill Bridge, steel vertical-lift bridge, completed in 1959, spanning the Arthur Kill (channel) between Elizabeth, N.J., and Staten Island, N.Y. The movable section, suspended from two 215-foot- (66-metre-) high towers, is 558 feet (170 m) long and can be raised 135 feet (41 m) above the water to allow ships to pass beneath it. It carries a single railroad track and, at its completion, was the longest and highest span of its type in the world.

Arthurian legend, the body of stories and medieval romances, known as the matter of Britain, centring on the legendary king Arthur (q.v.). Medieval writers, especially the French, variously treated stories of Arthur's birth, the adventures of his knights, and the adulterous love between his knight Sir Lancelot and his queen, Guinevere. This last situation and the quest for the Holy Grail (the vessel used by Christ at the Last Supper and given to Joseph of Arimathea) brought about the dissolution of the knightly fellowship, the death of Arthur, and the destruction of his kingdom.

Stories about Arthur and his court had been popular in Wales before the 11th century; European fame came through Geoffrey of Monmouth's *Historia regum Britanniae* (between 1135 and 1139), celebrating a glorious and triumphant king who defeated a Roman army in eastern France but was mortally wounded in battle during a rebellion at home led by his nephew Mordred. Some features of Geoffrey's story were marvelous fabrications, and cer-

tain features of the Celtic stories were adapted to suit feudal times. The concept of Arthur as a world conqueror was clearly inspired by legends surrounding great leaders such as Alexander the Great and Charlemagne. Later writers, notably Wace of Jersey and Layamon, filled out certain details, especially in connection with Arthur's knightly fellowship.

Using Celtic sources, Chrétien de Troyes (*q.v.*) in the late 12th century made Arthur the ruler of a realm of marvels in five romances of adventure. He also introduced the theme of the Grail into Arthurian legend. Prose romances of the 13th century began to explore two major themes: the winning of the Grail and the love story of Lancelot and Guinevere. An early prose romance centring on Lancelot seems to have become the kernel of a cyclic work known as the Prose *Lancelot*, or Vulgate cycle (*c.* 1225). The Lancelot theme was connected with the Grail story through Lancelot's son, the pure knight Sir Galahad, who achieved the vision of God through the Grail as fully as is possible in this life, whereas Sir Lancelot was impeded in his progress along the mystic way because of his adultery with Guinevere. Another branch of the Vulgate cycle was based on a very early 13th-century verse romance, the *Merlin*, by Robert de Boron, that had told of Arthur's birth and childhood and his winning of the crown by drawing a magic sword (*see* Excalibur) from a stone. The writer of the Vulgate cycle turned this into prose, adding a pseudo-historical narrative dealing with Arthur's military exploits. A final branch of the Vulgate cycle contained an account of Arthur's Roman campaign and war with Mordred, to which was added a story of Lancelot's renewed adultery with Guinevere and the disastrous war between Lancelot and Sir Gawain that ensued. A later prose romance, known as the post-Vulgate Grail romance (*c.* 1240), combined Arthurian legend with material from the Tristan romance.

The legend told in the Vulgate cycle and post-Vulgate romance was transmitted to English-speaking readers in Thomas Malory's late 15th-century prose *Le Morte Darthur*. At the same time, there was renewed interest in Geoffrey of Monmouth's *Historia*, and the fictitious kings of Britain became more or less incorporated with official national mythology. The legend remained alive during the 17th century, though interest in it was by then confined to England. Of merely antiquarian interest during the 18th century, it again figured in literature during Victorian times, notably in Alfred Tennyson's *Idylls of the King*. In the 20th century an American poet, Edwin Arlington Robinson, wrote an Arthurian trilogy, and in England T.H. White retold the stories in a series of novels collected as *The Once and Future King* (1958). *Camelot* (1960), a musical by Alan Lerner and Frederick Loewe, was based on White's work. *See also* Grail.

ārtī (Hindi), Sanskrit **ĀRĀTRĪKA**, in Hindu and Jaina rites, the waving of lighted lamps before an image of a god or a person to be honoured. In performing the rite, the worshiper circles the lamp three times in a clockwise direction while chanting a prayer or singing a hymn. *Ārtī* is one of the most frequently observed parts of both temple and private worship (*see* puja). The god is honoured by the lighted ghee (clarified butter) or camphor and is protected by the invocation of the deities of the directions of the compass. In Indian households, *ārtī* is a commonly observed ritual treatment accorded specially honoured guests. It is also a part of many domestic ceremonies.

Artibonite River, French **RIVIÈRE DE L'ARTIBONITE**, Spanish **RÍO ARTIBONITO**, river, the longest on the island of Hispaniola. It rises in the Cordillera Central (Ciboa Mountains) of

the Dominican Republic and flows southwest along the border with Haiti and then west and northwest into Haiti and through the fertile

Péligre Dam on the Artibonite River, Haiti
Adams and Adams

Artibonite Plain to enter the Gulf of Gonaïves after a course of 150 miles (240 km). It is navigable upstream for about 100 miles (160 km) by small craft. Large tracts of irrigated land were developed as part of the Artibonite Valley Agricultural Project. The focus of the project was the Péligre Dam, which was initiated in 1930 as a flood-control project; its completion in 1956 resulted in the creation of a large reservoir (Péligre Lake). Soil erosion, induced by forest denudation in the Artibonite valley, has resulted in severe siltation of the reservoir and has greatly reduced its agricultural and energy potential. The Péligre hydroelectric operation, completed in 1971, supplies much of Haiti's electricity.

artichoke, also called **FRENCH**, or **GLOBE**, **ARTICHOKE**, large, coarse, herbaceous, thistle-like perennial plant (*Cynara scolymus*) of the Asteraceae family. The thick edible scales and bottom parts of the immature flower heads are a culinary delicacy. The bottom part of the immature flower head is called a heart.

The aboveground parts of the plant die each year after flowers are formed; new shoots arise the next season to produce rosettes of deeply cut, woolly leaves up to 1 m (3.3 feet) long; later, sturdy, branched flower stalks rise; their flowers are purplish. After four to eight years the cluster of rosettes from a crown becomes crowded, and the size and quality of the heads become reduced. The plant is then renewed by planting divisions of the crown or rooted offshoots. The mature flower heads produce seeds, but the seedlings do not necessarily resemble the variety of the parent plant.

The artichoke is native to the western and central Mediterranean, whence it was carried to the eastern Mediterranean in ancient times. At that time the young leaves rather than the immature flower heads were eaten; the edible-

Artichoke (*Cynara scolymus*)
Ingmar Holmasen

flower form was first recorded in Italy about 1400. Today it is extensively cultivated in California, France, Belgium, the Mediterranean countries, and other regions with the necessary rich soil and mild, humid climate.

The artichoke's flavour is delicate and nut-like, and the smaller heads, or buds, are usually the most tender. Artichoke heads are served as a hot vegetable with a sauce or as a cold salad or appetizer.

The Jerusalem artichoke (*q.v.*) is a tuber and does not resemble the artichoke.

Articles of Confederation: *see* Confederation, Articles of.

Articulatae (botany): *see* Sphenophyta.

articulation, in phonetics, a configuration of the vocal tract (the larynx and the pharyngeal, oral, and nasal cavities) resulting from the positioning of the mobile organs of the vocal tract (*e.g.*, tongue) relative to other parts of the vocal tract that may be rigid (*e.g.*, hard palate). This configuration modifies an airstream to produce the sounds of speech. The main articulators are the tongue, the upper lip, the lower lip, the upper teeth, the upper gum ridge (alveolar ridge), the hard palate, the velum (soft palate), the uvula (free-hanging end of the soft palate), the pharyngeal wall, and the glottis (space between the vocal cords).

Articulations may be divided into two main types, primary and secondary. Primary articulation refers to either (1) the place and manner in which the stricture is made for a consonant or (2) the tongue contour, lip shape, and height of the larynx used to produce a vowel. The primary articulation may still permit some range of movement for other articulators not involved in its formation. For example, an "apico alveolar" articulation involves the tip of the tongue but leaves the lips and back of the tongue free to produce some degree of further stricture in the vocal tract. This latter is called a secondary articulation. Among the chief secondary articulations are palatalization, as in Russian and many other languages (the front of the tongue approaching the hard palate); velarization (the back of the tongue approaching the soft palate, or velum); labialization (added lip-rounding), glottalization (complete or partial closure of the vocal cords); and nasalization (simultaneous passage of air through the nasal and oral tracts).

artificial heart, machine or mechanical pump that maintains blood circulation (and oxygenation) in the human body for varying periods of time. The heart-lung machine and mechanical heart are the two main types of artificial hearts.

Heart-lung machine. The heart-lung machine is a mechanical pump that maintains a patient's blood circulation during heart surgery by shunting blood away from the heart, oxygenating it, and returning it to the body. The machine thus essentially consists of an artificial lung (oxygenator) and a substitute heart (pump). For nearly a century, beginning about 1868, scientists tried to develop a mechanical unit capable of restoring oxygen to blood depleted of this element in its movement through the tissues and removing the excessive carbon dioxide that accumulates during this same passage. Many investigators also worked on the development of a pump to supplant heart action temporarily. Decades of animal investigation culminated in the first successful application of an artificial heart-lung machine to an operation on a human being, by John H. Gibbon, Jr., on May 6, 1953.

For intervals of an hour or more a heart-lung machine can accept the entire venous return of a patient weighing as much as 100 kg (200 pounds). The blood is pumped back into the patient's arteries in a volume sufficient to maintain life at even the most distant parts of the patient's body as well as in those centres with the greatest requirements (brain and nervous tissue, liver, adrenals, kidneys). To do this, up to 5,000 millilitres (about 1.3 gallons) or more of blood must be moved each minute. While the heart is relieved of its pumping duties, it can be stopped by drugs or cooling and then started by warming or electrical means. Meanwhile, the surgeon can open this organ and repair or replace valves or close abnormal holes inside. The heart-lung machine can support a person's circulation

for only a few hours; if it is used for longer periods, the blood is damaged by the pumping and oxygenation.

Mechanical hearts. Instruments capable of replacing the pumping action of the normal heart for prolonged periods of time, without excessively damaging either the fluid or the cellular elements of whole blood, have been the goal of continuing research. On the way to this goal, several kinds of appliances have been tried that are designed to reduce, rather than take over entirely, the total work load of a heart with impaired functional capacity.

In general these units consist of either counterpulsation (diastolic augmentation) equipment that pulses the blood during the heart's "resting" phase between beats or an artificial auxiliary ventricle that substitutes temporarily by pumping a portion of the normal cardiac output. Use of these devices under experimental conditions has provided certain limited benefits to the circulation, including the heart; but the benefits are achieved at the expense of hazards to health with prolonged use. During the 1970s synthetic materials were developed that overcame most of the medical drawbacks and greatly aided the development of permanent artificial hearts. One such device, designed by Robert K. Jarvik, was surgically implanted into a patient by William C. DeVries on Dec. 2, 1982. The aluminum-and-plastic device, which was called the Jarvik-7 after its inventor, replaced the two lower chambers (ventricles) of the natural heart; its two rubber diaphragms, designed to mimic the pumping action of the natural heart, were kept beating by an external compressor that was connected to the implant by hoses. No oxygenation was required, because with an artificial heart the patient's lungs are not bypassed. This first patient to receive a permanent artificial heart survived 112 days and died as a result of various physical complications caused by the implant. Several subsequent patients who received artificial hearts fared little better or even worse. The consensus was that the existing technology could not yet produce a permanent artificial heart that functioned as well as a natural one and that such artificial hearts should be used only as temporary replacements in needy patients until suitable natural hearts could be obtained for transplantation. See also pacemaker.

artificial insemination, the introduction of semen into the vagina or cervix of a female by any method other than sexual intercourse. The procedure has become widely used in animal breeding and for the impregnation of women whose husbands are sterile or impotent.

The practical use of artificial insemination in animals was developed during the early 1900s in Russia and spread to other countries in the '30s. Its chief advantage is that the desirable characteristics of a bull or other male livestock animal can be passed on more quickly and to more progeny than if that animal were mated with females in a natural fashion. Ten thousand or more calves have been produced annually from a single bull through the use of artificial insemination. In the actual procedure used, semen is obtained from a male animal and, after being diluted, is deep-frozen, after which it can be stored for long periods of time without losing its fertility. For use, the semen is thawed and then introduced into the genital tract of a female animal.

In humans, artificial insemination has become a useful, if somewhat controversial, technique to impregnate women who are physically capable of conceiving and bearing a child but who cannot do so through sexual intercourse, usually because their husband is sterile or impotent. Fresh semen is obtained from the husband (if he is impotent) or from some other male donor (if the husband is sterile) and is introduced by a syringe into the

woman's vagina or cervix during the middle of her menstrual cycle. The semen can also have been previously frozen and stored in a sperm bank. The technique is reasonably successful in achieving conception and pregnancy, although the delicate moral issues surrounding it have yet to be fully resolved.

artificial intelligence (AI), the capacity of a digital computer or computer-controlled robot device to perform tasks commonly associated with the higher intellectual processes characteristic of humans, such as the ability to reason, discover meaning, generalize, or learn from past experience. The term is also frequently applied to that branch of computer science concerned with the development of systems endowed with such capabilities.

A brief treatment of artificial intelligence follows. For full treatment, see MACROPAEDIA: Artificial Intelligence.

Research on artificial intelligence began soon after the development of the modern digital computer in the 1940s. Investigators quickly recognized the potential of computing devices as a means of automating thought processes and soon tested their theories with chess-playing and theorem-proving programs.

Some computer programs that are used to perform AI tasks are designed to manipulate symbolic information at extremely high speeds, in order to compensate for their partial lack of human knowledge and selectivity. Such programs are usually called "expert systems." Other programs are designed to simulate human capabilities for problem solving through the use of highly selective search and recognition methods, rather than through superhuman processing speeds. Both expert systems and programs simulating human methods have attained the performance levels of human experts and professionals in performing certain specific tasks, but by the mid-1990s there were still no programs that could match human flexibility over wider domains or in tasks requiring much everyday knowledge.

Knowledge-based expert systems enable computers to make decisions for solving complicated nonnumerical problems. These expert systems consist of hundreds or thousands of "if-then" logic rules formulated with knowledge gleaned from leading authorities in a given field. The MYCIN program, for example, has been used to help physicians diagnose certain forms of bacterial blood infections and to determine suitable treatments. A computer programmed in MYCIN first makes a plausible guess as to the patient's condition on the basis of observed symptoms, then determines how well that tentative diagnosis fits all known facts about the behaviour of the microorganism thought to be involved. Once the computer has identified the cause of the infection, it reviews the kinds of antibiotics available and recommends one or several alternative forms of therapy.

Programs have also been developed that enable computers to comprehend commands in a natural language—*e.g.*, ordinary English. The software systems of this type that have been produced so far are limited in their vocabulary and knowledge to specific, narrowly defined subject areas. They contain large amounts of information about the meaning of words pertaining to that subject, as well as information about grammatical rules and common violations of those rules.

The ability to identify graphic patterns or images is associated with artificial intelligence, since it involves both cognition and abstraction. In a system designed with this capability, a device linked to a computer scans, senses, and transforms images into digital patterns, which in turn are compared with patterns stored in the computer's memory. The stored patterns can represent geometric shapes and forms that the computer has been pro-

grammed to (or has learned to) identify. The computer processes the incoming patterns in rapid succession, isolating relevant features, filtering out unwanted signals, and adding to its memory any new patterns that deviate beyond a specified threshold from the old and are thus perceived as new entities.

Major and continuing advances in computer processing speeds and memory sizes have facilitated the development of AI programs. Although most AI programs attempting to simulate higher mental functions incorporate the bottleneck of limited short-term memory, which restricts humans to carrying out one or a few mental tasks at a time, many investigators have begun to explore how the intelligence of computer programs can be enhanced by incorporating parallel processing—*i.e.*, the simultaneous execution of several separate operations by means of computer memories that allow many processes to be carried out at once. The question of which portions of the human brain (and their corresponding thought processes) operate serially and which operate in parallel has been a topic of intense debate by researchers in both the cognitive sciences and AI, but no clear verdict had been reached by the mid-1990s.

The largest computer memories now contain elementary circuits that are comparable in number to the synaptic connections (about 10 trillion) in the human brain, and they operate at speeds (billions of operations per second) that are far faster than elementary neural speeds (which are at most thousands of operations per second). The challenge driving AI research is to understand how computers' capabilities must be organized in order to reproduce the many kinds of mental activity that are comprised by the term "thinking." AI research has thus focused on understanding the mechanisms involved in human mental tasks and on designing software that performs similarly, starting with relatively simple ones and continually progressing to levels of greater complexity. (H.A.Si.)

artificial jaundice: see carotenemia.

artificial organ, any machine, device, or other material that is used to replace the functions of a faulty or missing organ or other part of the human body. Artificial organs include the artificial heart and pacemaker (*qq.v.*), the use of dialysis (*q.v.*) to perform kidney functions, and the use of artificial substitutes for missing limbs (see prosthesis).

artificial respiration, breathing induced by some manipulative technique when natural respiration has ceased or is faltering. Such techniques, if applied quickly and properly, can prevent some deaths from drowning, choking, strangulation, suffocation, carbon monoxide poisoning, and electric shock. Resuscitation by inducing artificial respiration consists chiefly of two actions: (1) establishing and maintaining an open air passage from the upper respiratory tract (mouth, throat, and pharynx) to the lungs and (2) exchanging air and carbon dioxide in the terminal air sacs of the lungs while the heart is still functioning. To be successful such efforts must be started as soon as possible and continued until the victim is again breathing.

The most widely used method of inducing artificial respiration is mouth-to-mouth breathing, which has been found to be more effective than the manual methods used in the past. The person using mouth-to-mouth breathing places the victim on his back, clears his mouth of foreign material and mucus, lifts the lower jaw forward and upward to open the air passage, places his own mouth over the victim's mouth in such a way as to establish a leak-proof seal, and clamps the nostrils.

He then alternately breathes into the victim's mouth and lifts his own mouth away, permitting the victim to exhale. If the victim is a child the rescuer may cover both the victim's mouth and nose. The rescuer breathes 12 times each minute (15 times for a child and 20 for an infant) into the victim's mouth.

One method of artificial respiration, known as the modified Sylvester chest-pressure-arm-lift technique, is used if mouth-to-mouth breathing is not possible. The victim is placed faceup, and the shoulders are elevated to allow the head to drop backward. The rescuer kneels at the victim's head, facing him, grasps the victim's wrists, and crosses them over the victim's lower chest. The rescuer rocks forward, pressing on the victim's chest, then backward, stretching the victim's arms outward and upward. The cycle is repeated about 12 times per minute.

artificial selection, in biology, the selective breeding of animals and plants by humans. See selection.

Artigas, city, northwestern Uruguay. The city lies along the Cuareim River (Quaraí River in Brazil) across from Quaraí, Brazil, in the Santa Ana Hills (Santana Hills in Brazil). It was founded in 1852 as San Eugenio and was renamed in honour of José Gervasio Artigas, the national hero of independence. It is now a commercial and manufacturing centre for the surrounding agricultural and pastoral lands. Principal exports include cattle, jerked beef, wool, cereals, and fruit. The city has a television and a radio station. Artigas is linked by railroad and highway to Salto, and it has an airport.

Artigas is situated in one of the least densely populated regions in the nation. Like most of Uruguay, the surrounding area is ranching country. Its rolling, somewhat rocky pastures are good but subject to damaging droughts. There is some agriculture, with sugarcane, oranges, grapes, and corn (maize) being the principal crops. Black slaves were imported into northwestern Uruguay in the 18th and 19th centuries. When slavery was abolished in the 19th century, most of the slaves were sold to Brazil, and the few remaining did not form a distinct ethnic community. By 1850, owing to intermarriage and warring with white settlers, the pure-blooded Indian population had also vanished. Pop. (1985) 35,119.

Artigas, José Gervasio (b. June 19, 1764, probably Montevideo [now in Uruguay]—d. Sept. 23, 1850, Ibiray, near Asunción, Paraguay), soldier and revolutionary leader who is regarded as the father of Uruguayan independence, although that goal was not attained until several years after he had been forced into exile.

As a youth Artigas was a gaucho, or cowboy, in the interior of what is now Uruguay. In 1797 he entered the Spanish military forces, which then were mainly engaged in exterminating bandits. Several years later (1810) he offered his services to the Buenos Aires junta that was leading an independence movement against Spain. After winning a brilliant victory at Las Piedras, he besieged Spanish-held Montevideo for a time. In the face of superior Portuguese forces (called in from Brazil by the Spaniards), Artigas led a dramatic withdrawal of about 16,000 people from the region into Argentine territory.

Artigas then became the champion of federalism against the efforts of Buenos Aires to assert centralized control over the whole Río de la Plata region. In 1814 this struggle became a civil war. At first Artigas ruled over about 350,000 square miles (900,000 square km) of what is now Uruguay and central Argentina. His hold, however, was weakened

by his insistence on decentralized government and was finally broken by a Portuguese invasion, which he resisted for three years. From 1820 he lived in exile in Paraguay; the independence of his native Uruguay was finally achieved on Aug. 27, 1828.

artillery, in military science, crew-served big guns, howitzers, or mortars having a calibre greater than that of small arms, or infantry weapons. Rocket launchers are also commonly categorized as artillery, since rockets perform much the same functions as artillery projectiles, but the term artillery is more properly limited to large gun-type weapons using an exploding propellant charge to shoot a projectile along an unpowered trajectory.

A brief treatment of artillery follows. For full treatment, see MACROPAEDIA: War, The Technology of.

The dividing line between modern artillery and small arms is usually placed at a bore diameter, or calibre, of 0.60 inch or 15 mm. Weapons with a bore diameter greater than that are considered artillery, and those of smaller calibre are considered small arms. The term gun is reserved for a long-barreled, long-range artillery piece that fires its projectile in a relatively flat trajectory, while a howitzer has a shorter barrel and less range and shoots in a moderately arched trajectory. (Intermediate types capable of both functions are called gun-howitzers.) A mortar has a very short barrel, short range, and a hairpin trajectory owing to the high angle at which it is fired.

Modern artillery originated in the second half of the 19th century. Before that period, cannons and mortars had not changed fundamentally since their introduction in the 14th century. Made of cast bronze or brass, cast iron, or wrought iron, they were classified according to the weight of the spherical balls they fired (e.g., 12-pounder, 24-pounder). Artillery was generally deployed as horse (for use with cavalry), field (for the support of infantry), and garrison (for coastal and fortress defense). Pieces were hauled on two-wheeled carriages by teams of horses, while wagons called limbers carried ammunition, tools, spare parts, and crewmen. The short ranges of these weapons—and of enemy musket fire—meant that they were set up within sight of their targets. Upon firing, huge clouds of smoke were generated by the black-powder propellants, and the gun and carriage, having been thrown back by the recoil forces, had to be wrestled back into firing position. The bore was then swabbed out with a sponge to extinguish sparks, powder and shot were rammed from muzzle to breech, and the piece was fired again.

By the end of the 19th century, hydro-pneumatic piston arrangements allowed a fired artillery piece to recoil atop the carriage and then return to approximately the same firing position as before. Hence the gun did not have to be relaid (re-aimed) between shots. By this means, round after round could be fired as fast as the gun could be reloaded. Quicker reloading was facilitated by new mechanisms allowing the insertion of the ammunition into the gun through the breech rather than through the muzzle. Gun barrels were now made of forged steel, and their bores were threaded with rifling grooves. These imparted a stabilizing spin to projectiles, which acquired an elongated shape and were propelled far beyond visual range by more powerful, smokeless, nitrocellulose-based gunpowders. Both powder and projectile were fixed in a metal cartridge case called a shell, which could be loaded quickly into the breech of a weapon.

Since World War II, a common practice has been to distinguish between light, medium, and heavy artillery. Guns and howitzers up to 105 mm in calibre are called light, and those over 105 mm but not more than 155 mm are called medium. Light artillery supports ground

troops in attack and defense, and medium artillery adds the function of bombarding enemy artillery as well as troop concentrations and facilities just behind the combat area. Heavy artillery, which is also intended to attack installations to the rear, is frequently mounted on lightly armoured, tracked or wheeled vehicles. These and the larger medium pieces are designed to deliver projectiles to a target area 100 m (330 feet) in diameter from as far away as 25 km (15 miles). To add to the devastation of rear areas, the United States and the Soviet Union designed nuclear-armed projectiles as small as 155 mm. Among the conventional types of shells fired by artillery are high-explosive rounds, which are used against infantry, light vehicles, and aircraft; armour-piercing rounds, which are used to penetrate tanks and other armoured vehicles, naval vessels, and reinforced structures; and various chemical rounds, which may be used to produce smoke or provide illumination on the battlefield.

The coming of air power early in the 20th century led to the creation of the antiaircraft gun, a type of artillery that is also commonly divided into light (20 to 40 mm), medium (40 to 90 mm), and heavy (100 mm and more). Since World War II, all but the light antiaircraft guns have been rendered obsolete by tactical guided missiles, which have also caused the virtual disappearance of garrison artillery.

The growing importance of heavy tanks spurred the development in World War II of recoilless rifles. These light artillery pieces, which measure up to 105 mm in calibre, eliminated recoil upon firing by allowing propellant gases to escape through a nozzle in the breech. They fire low-velocity explosive projectiles that, along with the recoilless principle itself, have been applied to shoulder-held infantry weapons since the war.

Artin, Emil (b. March 3, 1898, Vienna, Austria—d. Dec. 20, 1962, Hamburg, W.Ger.), Austro-German mathematician who made fundamental contributions to class field theory, notably the general law of reciprocity.

After one year at the University of Göttingen, Artin joined the staff of the University of Hamburg in 1923. He emigrated to the United States in 1937, where he taught at Notre Dame University (1937–38), Indiana University, Bloomington (1938–46), and Princeton University (1946–58). In 1958 he returned to the University of Hamburg.

Artin's early work centred on the analytical and arithmetic theory of quadratic number fields. He made major advances in abstract algebra in 1926 and the following year used the theory of formal-real fields to solve the Hilbert problem of definite functions. In 1927 he also made notable contributions in hypercomplex numbers, primarily the expansion of the theory of associative ring algebras. In 1944 he discovered rings with minimum conditions for right ideals, now known as Artin rings. He presented a new foundation for and extended the arithmetic of semi-simple algebras over the rational number field.

His theory of braids, set forth in 1925, was a major contribution to the study of nodes in three-dimensional space. Artin's books include *Geometric Algebra* (1957) and, with John T. Tate, *Class Field Theory* (1961). Most of his technical papers are found in *The Collected Papers of Emil Artin* (1965).

artiodactyl, a member of the mammalian order Artiodactyla, which consists of the even-toed ungulates. These large and medium-size herbivores, familiar from barn-

yard, field, and zoo, are distributed among nine families: pigs (Suidae), peccaries (Tayassuidae), hippopotamuses (Hippopotamidae), camels (Camelidae), chevrotains (Tragulidae), giraffes and okapi (Giraffidae), deer (Cervidae), pronghorn (Antilocapridae), and cattle, sheep, goats, and antelope (Bovidae).

A brief treatment of artiodactyls follows. For full treatment, see MACROPAEDIA: Mammals.

The artiodactyls were a distinct group by the end of the Eocene epoch (36.6 million years ago). They demonstrated skill at adapting to environmental changes during the Oligocene epoch, which ended about 23.7 million years ago, and have remained prominent ever since. The 150 living species of the order are widely distributed. Deer, originally Eurasian, have spread to the Americas. Their close cousins the giraffe and okapi are at home in Africa, as are the hippopotamuses. Various bovids (which number almost 100 species) and pigs flourish in the Western and Eastern hemispheres, and the two peccaries live in Central and South America. The larger camels are native to Asia and Africa, but smaller members of the family, such as llamas and vicuñas, are found in South America. Three of the chevrotains live in the tropical forests of Asia, and one lives in Africa. The pronghorn, not a true antelope, lives in the grasslands of western America. The value of these mammals to man has always been great. They provide food in the form of meat and milk as well as clothing in the form of hides and wool, and in parts of the world camels are still used for transportation.

The artiodactyls are distinguished from the perissodactyls—the odd-toed ungulates such as horses and rhinoceroses—by the weight-bearing axis of the leg, which extends through the third and fourth toes together. (There is a fifth toe, but no first.) In the five-toed perissodactyls, the axis passes through the third, or central, toe. Another basic characteristic that identifies artiodactyls is the astragalus, an ankle bone that has rounded articulations at both ends and no constricted neck. This arrangement provides greater thrust when the animal runs, and, together with long legs and the ability to contract muscles quickly, it adds to the speed of most artiodactyls. The evolutionary success of the artiodactyls may be attributed to this and other adaptations of skeletal structures for swift flight and to the ability of members of the order to swallow food quickly and, in many cases, regurgitate it and chew it later.

Antlers and horns are found in many members of the order. Antlers, the hard, branched outgrowths of bone in the skull, are common on most male deer and are found on female reindeer as well. Males use antlers, which are shed seasonally and regrown, to fight and to mark territory. Combatants usually seek to avoid inflicting serious injury. Bovids of both sexes often have horns, but they are not regenerated if lost. Hair or fur, the latter sometimes beautifully coloured or patterned, covers the bodies of all members of the order except the hippopotamuses.

Advanced members of the order can bolt their food and then regurgitate and chew it, or ruminate, at a time of their choosing, such as when a threat from predators has passed. Most of these ruminants, who graze a variety of vegetation, have evolved a complex stomach containing four parts. Swallowed food passes from one part, the rumen, back into the mouth for complete mastication and is then swallowed again, after which it passes through the three other chambers, specialized for the digestion of a largely cellulose diet.

Courtship among artiodactyls may be more or less elaborate, often beginning with the male sniffing the female's urine, perhaps to determine if she is in heat. Contact such as nuzzling or taps on the leg may precede mating. Gestation periods range from 4 to 14 months. A placenta joined to the mother's

womb is the organ through which the fetus breathes, feeds, and eliminates waste. Single births are the rule, although some species of deer bear twins, and the number may range to five for the European wild pig.

Reliance on milk lasts at least a few months, but all young eventually join in the endless search for food, to which snow, fire, and competition from other herbivores pose the chief problems. Adaptations to the search for food include the snout and tusks of pigs and the thickened skin that protects the warhog foraging under low bushes. Chevrotains, frequenting the thick undergrowth near water, have added roots and tubers to their diet. Another dietary specialization is that of the reindeer, which prefer lichens during the winter. The preference of different species of herbivores for different plants permits a number of species to flourish in the same geographic area.
